measure, to sequence in the general testimony of those who have seen it in its native waters, and who declared it to be at length transmuted, not into a frog, but a fish! and it was even added by some, that it afterwards reverted to its tadpole form again! That it is really no other than a frog in its larva or tadpole state, will be evident to every one who considers its structure; and more especially, if it is collated with the tadpole even of some European frogs. Like our common European tadpoles, this animal, according to the more or less advanced state in which it is found, is furnished either with all the four legs, or with only the two hinder ones; it also sometimes happens that in the largest-sized of these tadpoles, exceeding perhaps the length of six or eight inches, the hind legs alone appear; while in those of far smaller size both the fore and hind legs are equally conspicuous.

It will readily appear that the larva of this frog is larger in proportion to the complete animal than in any other species hitherto discovered. From which we may observe, that perhaps all the specimens of these very large tadpoles occurring in museums, may not be those of the true para-doxa in particular, but of some other American, African, or Asiatic frogs, as the R. occulta, marina, &c. See FROG-FISH, Vol. I. p. 780.

Hylæ, or frogs with rather slender bodies, long limbs, and the tips of the toes flat, orbicular, or dilated.

6. Rana zebra, zebra-frog, appears to be by far the largest of all the Hylæ, or slender- bodied frogs, and is, according to Sota, a native of Carolina and Virginia. Its colour is an elegant pale russet-brown, beautifully marked on the back and limbs, and even to the ends of the toes, with transverse chestnut-coloured bands, which on the limbs are double and much more numerous than on the back; the fore feet are tetradactylous, and the hind pentadactylous; the head is large in proportion, the eyes prominent, and the mouth wide. It measures about five inches.

7. Rana purpurea, the fire-frog, is remarkable for its colours, as well as in the elegance of its form and the agility of its movements, the tree-frog exceeds every other European species. It is a native of France, Germany, Italy, and many other European regions, but is not found in the British islands. Its principal residence, during the summer months, is on the upper parts of trees, where it wanders among the foliage in quest of insects, which it catches with extreme celerity, seizing softly toward its prey in the manner of a cat toward a mouse, and while at the proper distance, seizing it with a sudden spring, frequently of more than a foot in height. It often suspends itself under the leaves of trees; it is thus concealed. The leaf is then continued concealed beneath their shade. Its size is smaller than any other European frog, except the fire-frog. Its colors vary in the upper part is green, more or less bright to its different individuals; the abdomen is white, and marked by numerous granules; the under surface of the limbs is reddish, and the body marked on each side by a longitudinal blackish or violet-coloured streak. The body is smooth above, and moderately short above; the hind legs are very long and slender; the toe feet have four and the hind feet five toes, all of which terminate in rounded, flat, and dilated tips, the under surface of which, being soft and glutinous, enables the animal to hang with perfect security from the leaves of trees, &c. The skin of the abdomen is also admirably adapted to this purpose, forming a kind of adhesion, covered with small granular granules in such a manner as to fasten closely even to the most polished surface; and the animal can adhere at pleasure to that of glass, in whatever position or inclination it is placed, by merely pressing itself against it.

Though the tree-frog inhabits the woods during the summer months, yet on the approach of winter it retires to the waters, and there submerging itself in the soft mud, or concealing itself beneath the banks, remains in a state of torpidity, and again emerges in the spring, at which period it deposits its spawn in the waters, like the rest of this genus.

During their residence among the trees, they are observed to be particularly noisy on the approach of rain; so that they may be considered, in some measure, as a kind of barometer; more especially the males, which, if kept in glasses, and supplied with proper food, will afford an infallible presage of the changes of weather.

Toads. 8. Rana bufo, common toad. Of all the European toads, this seems to be the most universally known; at least, in its complete or perfect form. It is found in gardens, woods, and fields; and frequently makes its way into cellars, or any obscure recesses in which it may occasionally conceal itself, and which it may, or may not, if found of sufficient security from the too great a degree of cold. In the early part of spring, like others of this genus, it returns to the waters, where it continues during the breeding-season, and deposits its spawn in the form of double necklace-like chains or strings of beautifully transparent glutens, and of the length of three or four feet.

The toad is an animal too well known to require any very particular description of its form. It may be observed, that it is always covered by tubercles, or elevations on the skin, of larger or smaller size in different individuals; and that the general colour of the animal is an obscure brown above, much paler and irregularly spotted beneath.

The toad arrives at a considerable age; its general term of life being supposed to extend to 15 or even 20 years; and Mr. Pennant, in his British Zoology, gives us a curious account, communicated by a Mr. Ascott of Tething in Devonshire, of a toad's having lived, in a kind of domestic state, for the space of more than 40 years, and of having been in a great degree tamed, or rather from its natural vivacity, to desire of concealment, since it would always regularly come out of its hole at the approach of its master, &c. In order to be fed. It grew to a very large size, and was considered as so singular a curiosity, that even ladies, laying aside their usual aversion and prejudices, requested to see the favourite toad. It was, therefore, often brought to table, and fed with various kinds of morsels; at least, with those which, by persons of unphilosophical minds, can support a long abstinence, and requires but a small quantity of air; but in the accounts generally given of toads discovered in stones, wood, &c. the animals are said to
have been completely impacted or imbedded, and without any space for air.

9. Rana viridis. The green toad is a native of Germany and some other parts of Europe, and seems to have been first described by Valenciennes, and afterwards by Lauter, who informs us that it inhabits the cavities of walls about Vienna, and is distinguished by its greenish and confluent spots on the upper parts, disposed on a pale or brownish ground, and usually reaching over the shoulders. Each of the green spots or patches is also bordered by a blackish margin, and the whole pattern has a somewhat rude and somewhat map-like appearance. The colour of the skin is very variegated, being that of the common black or garden nightshade, but much more powerful, so as to fill a whole room. The female is of a browner cast than the male. In winter this species lives under ground, and, like other species of the genus, frequents the waters at the breeding season.

10. Rana dubia, or musca. Of this animal a specimen is preserved in the national Museum, of which I have a map of the post: its size is that of a common toad, but the shape of the body differs, seeming gradually to decrease from the shoulders to the hind legs, somewhat in the manner of those of the night-frog. Its colour, so far as can be determined from the specimen long preserved in spirit of wine, appears to have been a moderately deep brown above, and pale or whitish beneath, yellowish or red at the back with brown. The whole upper surface is beset with distinct oval punctures or tubercles.

Whether this is the species intended by Linnaeus, under the name of rana musca, very probably is uncertain. In the former, Nature he refers to no author or figure, but informs us that the animal is a native of Surinam, and that it has a musical voice.

11. Rana pipa. pipa. This is also called the common toad. Among the whole tribe of amphibia, it is, perhaps, difficult to find an animal of more singular appearance than this, which may be regarded as a more deformed and ridiculous animal than even the common night-frog. This arises not so much from the general shape of the animal, as from the extraordinary structure of the upper eyelids, which are so formed as to resemble a pair of short sharp-pointed horns; the shape of the mouth is such as to exceed that of any other species, and even to equal half the length of the body itself. The skin of the body, both above and below, is of a most disgusting brown. Along the back runs a broad white band, commencing at the head, and thence decreasing gradually, so as to appear narrow over the hind parts; it is also imparted with small greenish spots. All the rest of the body is rough, with sharp spines, except the head, which is variegated with white, and the abdomen, which is of a deep ruby yellow. The legs are furnished with small quills; the hands and the toes are marked in a similar manner, and resemble in some degree the human fingers, and are four in number on the fore legs, and five on the hind; the hind feet are also furnished with small quills. The head is very large and thick, and when the mouth is opened, exhibits a broad and thick tongue, shaped somewhat like an oyster, and fastened in to the lower jaw, but loose behind as in frogs; it is also covered over with papillae. The female agrees in all respects with the male, except that the mouth is still wider, and the front is greater in a somewhat different manner. See Plate Nat. Hist. fig. 343.

Selma seems to have been misinformed as to the native country of this species, which he imagined to be Virginia; but the animal is now known to be a native of South America only.

12. Rana pipa. This is also one of those animals which, at first view, every one pronounces deformed and hideous; the general uncouthness of its shape being often exaggerated by a phenomenon unexampled in the rest of the animal world, viz. the young in various stages of exclusion, proceeding from cells dispersed over the back of the parent.

The size of the pipe considerably exceeds that of the common toad: the body is of a flattened form; the head male is longer, with the edges or corners furnished with a kind of short cutaneous and lacertated appendage on each side; in the male, however, the head is rather oval than triangular, and the pointed less distinct; the fore feet are tetrads, the toes long and thin, and each divided at the tip into four distinct processes or processes, each of which, if narrowly examined with a magnifier, will be found to be from an obscurely subdivided almost in a similar manner; the hind feet are five-toed, and very widely webbed; the web reaching to the very tips of the toes. The male pipe is larger than the female, measuring much less than seven inches from the nose to the end of the body; the nose in both sexes is of a somewhat truncated form, like that of a mole or hog, and the eyes very small, from each eye, in the female, run two rows of granules, or glandular points, to the middle of the back; the whole body is also covered with similar points or glandules, but smaller than the former. The granules proceed from each eye down the back, instead of a double row as in the female: these points or granules are also larger than in the female, and gradually decrease in size as they pass from the lower part of the back; the skin round the neck, in both sexes, forms a kind of loose or wrinkled collar: the abdomen of the male is of a brownish tinge than that of the female, and is sometimes obscurely spotted with yellow; but the general colour, both of the male and female pipe, is a dark or blackish brown.

It was for a long time supposed that the ova or eggs of this extraordinary animal were produced in the bursal cells, without having been first excluded in the form of spawn; but later observations have proved that a still more extraordinary process takes place; and that the spawn after exclusion is received into the open cells of the back, and then concealed till the young have arrived at maturity. The female pipe deposits her eggs or spawn at the brink of some stagnant water; and the male collects or amasses the heap of ova, and deposits them on the female, where, after impregnation, they are pressed into the cells, which are at that period open for their reception, and afterwards close over them; thus retaining them till the period of their second birth, which happens in somewhat less than three months, when they emerge from the back of the parent in their complete state. During the time of their concealment, however, they undergo the usual change of the rest of the genus, being first hatched from the eggs in the form of a tadpole; and generally acquire their complete shape some time before their exclusion.

According to Fermin, the pipe is calculated by nature for producing but one brood of young; and, compared with the rest of the genus, it can by no means be considered as a very prolific animal; the number of young produced by the female which he observed, amounted to 75, and were all excluded within the space of five days.

RANCIDITY, the effect of Oils.

RAN.

RANDOM SHOT, in gunnery, is a shot made when the muzzle of a gun is raised above the horizontal line, and is not designed to shoot directly or point blank. The utmost random of any piece is about 40°; the mouth very seldom goes 45°. To shoot a bullet will go farthest when the piece is mounted to about 45° above the level range. See GUNNERY, and PROJECTILE.

RANGE, in gunnery, the path of a bullet, or the line it describes from the mouth of the piece to the point where it lodges. If the piece is in a line parallel to the horizon, it is called the right or level range: if it is mounted to 45°, it is said to have the utmost range; all others between 60° and 45° are called the intermediate rangs.

RANGER, a sworn officer of a forest, appointed by the king's letters-patent, whose business is to act through his charge, to drive back the deer out of the purifier, &c. and to present all trespassers within his jurisdiction at the next forest-court.

RANGES, in a ship, two pieces of timber that go across from side to side; the one on the forecastle, a little abait the fore-mast; and the other in the beak-head, before the waulings of the bowsprit.

RANK, in war, is a row of soldiers placed side by side.

To double the ranks is to put two ranks into one. To close the ranks is to bring the men together and to open them, is to set them farther apart.

RANK, the order or place assigned a person suitable to his quality or merit. See PRECEDENCE.

Rank and precedence, in the army and navy, are as follows:

Engineer's rank. Chief, as colonel; di-rector, as lieutenant-colonel; sub-director, as major; engineer in ordinary, as captain; engineer extraordinary, as captain-lieutenant; sub-engineer, as lieutenant; practitioner engine-

Navy rank. Admiral, or commander-in-chief of his majesty's fleet, has the rank of a field-marshal; admirals with their flags on the main-topmast head, rank with generals of horse and foot; vice admirals, with lieute-

RAmap. See Brassica.

Rape, in law, is where a man has carnal knowledge of a woman by force, and against her will; by 18 Eliz. c. 7, if any person shall unlawfully and carnally know and abuse any woman-child under the age of ten years, whether with her consent or against it, he shall be punished as for a rape. And it is not a sufficient excuse in the ravisher, to prove that she is a common strumpet; for she is still under the protection of the law, and may not be forced. Nor is it the offence of a rape mitigated by showing that the woman at last yielded to the violence, if such her consent was forced by fear of death or torture; nor is it any excuse that she consented after the fact. 1 Haw. 108.

The civilians make another kind of rape, called rape of subordination or seduction; which is seducing a maid either to uncleanness or marriage, and that by gentle means; provided there is a considerable disparity in the age and circumstances of the parties.

Rape is also a name given to a division of a county, and sometimes means the same as a hundred, and at other times signifies a division consisting of several hundreds; thus Saxe is divided into six rapes, every one of which, besides its hundreds, has a castle, a river, and a forest, belonging to it. The like parts in other counties are called titheings, lathes, or rententakes.

Raphanus, radish, a genus of the silique order, in the tetradymana class of plants; and in the natural method ranking under the 39th order, siliqueous. The calyx is close: the silique torose, or swelling out in knots, subarticulated, and round. There are two melfillicel glandules between the shorter stamina and the pistil, and two between the longer stamina and the calyx. There are six species; the saline, or common garden-radish, is best known, and of these there are several varieties. They are annual plants, which being sown in the spring, attain perfection in two or three months, and shoot up soon after into stink, for flower and seed, which, ripening in autumn, the whole plant, root and top, perishes; so that a fresh supply must be raised annually from seed in the spring, performing the sowings at several different times, from about Christmas to May, in order to continue a regular succession of young tender radishes throughout the season, allowing only a fortnight or three weeks interval between the sowings; for one crop will not continue good longer than that space of time, before they will either run to seed, or become tough, sticky, and too hot to eat.

Raphidia, a genus of insects of the order neuroptera. The generic character is, mouth with two teeth; head depressed, humpy; feeders four; stemmata three; wings deltex; antennae the length of thorax, which is cylindrical, and elongated in front; tail of the female furnished with a recurved lase bristle. This genus contains but few species, the most remarkable of which is the raphidia ophthalmus of Linnaeus; a smallish fly, with rather large transparent wings, and a narrow thorax, stretching forwards in a remarkable manner. It is found on trees, &c. in summer, but is rather a rare insect; the pupa, according to Linnaeus, resembles the complete insect, but is destitute of wings.

Raphidota coronta is a large species, equal in size to one of the larger dragon-flies, and is distinguished by its very long homelike jaws, which extend far beyond the thorax, and are terminated by a bind lip; the wings are large, reticulated, and semitransparent. It is a native of North America.

Raphidota mautspa is a small species, but little superior is size to the R. ophthalmus, and is a native of some of the warmer parts of Europe. It has the habit of the genus mauspa, and it is even doubtful whether it should not more properly be referred to that genus.

Raphidota, in physics, the act whereby a body is brought to possess more room, or appear under a larger bulk, without the accession of any new matter. This is commonly the effect of caloric, as has long been universally allowed. In many cases, however, philosophers have attributed it to the action of a repulsive principle. However, from the many discoveries concerning the nature and properties of the electric fluid and caloric, there is the greatest reason to believe that this repulsive principle is no other than other caloric or hire.

Rasent, or Razant, in fortification, Rasant flank, or line, is that part of the curtin or flank whence the shot exploded rase, or glance along, the surface of the opposite bastion.

Rash, in medicine, an eruption upon the skin, thrown out in fevers or surfeits. See Medicine.
RAT

RAT, or Marlinpike, in clock-work, a sort of wheel having twelve fangs, which serve to lift up the detents every hour, and make the clock strike hourly.

RATCHETS, in a watch, are the small teeth at the bottom of the fusee, or barrel, which stops it in winding up.

RATES, in the navy, the orders or classes into which the seamen are divided, according to their force and magnitude. The regulation which limits the rates of men of war to the smallest number possible, seems to have been determined by considerations of political economy; or, the simplicity of the service in the royal dock-yards.

The British fleet is accordingly distributed into six rates, exclusive of the inferior vessels that usually attend the ships of war, armed ships, bomb-ketches, fire-ships and cutters, or schooners commanded by lieutenants. Ships of the first rate mount 100 cannon, having 42-pounders on the lower deck, 24-pounders on the middle deck, 12-pounders on the upper deck, and 9-pounders on the quarter-deck and forecastle. They are manned with 850 men, including their officers, seamen, marines, and armed sloops.

In general, the duties of every rate, besides the captains, have the master, the boatswain, the gunner, the chaplain, the purser, the surgeon, and the carpenter; all of whom, except the captain, have their mates or assistant, in which are comprehended the sailmaker, the master at arms, the armourer, the captain's clerk, the gunsmith, &c. The number of other officers is always in proportion to the rate of the ship. Thus a first-rate has six lieutenants, six master's mates, twenty-four midshipmen, and five Surgeon's mates, who are considered as gentlemen; besides the following petty officers; quarter-masters, and their mates; boatswain's mates and yeomen, eight; gunner's mates and assistants, six; quarter-gunnery twenty-five; carpenter's mates, two, besides fourteen assistants; with one steward, and steward's mate to the purser.

If the dimensions of all ships of the same rate were equal, it would be the simplest and most perspicuous method to collect them into the span of view in a table; but as there is no invariable rule for the general dimensions, we must content ourselves with but a few remarks on ships of each rate, so as to give a general idea of the difference between them.

The Victory, one of the last-built of our first-rates, and ever memorable for being commanded by Lord Nelson in the glorious battle of Trafalgar, is 222 feet 6 inches in length, from the head to the stern; the length of her keel, 154 feet 3 inches; that of her gun-deck, or lower deck, 180 feet; her extreme breadth is 51 feet 10 inches; her depth in the hold, 21 feet 6 inches; her burthen 2162 tons; and her poop reaches 6 feet before the mainmast.

Ships of the second rate carry 90 guns upon three decks, of which those on the lower battery are 32-pounders; those on the middle, 18-pounders; on the upper deck, 12-pounders; and those on the quarter-deck, mates, six 6-pounders, and yeomen, six gunner's mates and yeomen, with 22 quarter-gunnery, two carpenter's-mates with ten assistants, and one steward and steward's mate.

Ships of the third rate carry from 64 to 80 cannon; the largest have six-pounders; and the smallest, viz. those of 8 or 10 guns, four-pounders. Their officers are generally the same as in the 6th rate, with little variation; and their complement of great delays is to keep the officers to the force or magnitude. Bomb-vessels are on the same establishment as sloops; but fire-ships and hospital ships are on that of fifth rates.

Noolding the second rate excellently manifests the great improvement of the marine art, and the degree of perfection to which it has arrived in Britain, than the facility of managing our first rates; which were formerly extremely unmanageable. The crew of their upper deck being the same as those on the quarter-deck and forecastle of the latter, which are 9-pounders. The complement in a 74 is 155, and in a 64, 500 men; having, in peace, four lieutenants, but in war, five; and when an admiral is aboard, six. They have three master's-mates, 16 midshipmen, three surgeon's-mates, 10 quarter-masters and their guns, 30 9-pounders, 6 guns, 14 gunner's-mates and yeomen, with 18 quarter-gunnery, one carpenter's-mate with eight assistants, and one steward and steward's mate under the purser.

Ships of the fourth rate mount from 60 to 70 guns, upon two decks, and the quarter-deck. The lower tier is composed of 24-pounders, the upper tier of 12-pounders, and the cannon on the quarter-deck and forecastle are 6-pounders. The complement of a 50-gun ship is 320 men, in which there are three lieutenants, two master's-mates, 10 midshipmen, two surgeon's-mates, eight quarter-masters and their mates, four boat-swind's mates and yeomen, one gunner's mate and one yeoman, with 12 quarter-gunners, one carpenter's-mate and six assistants, and a steward and steward's-mate.

Vessels of war under the fourth rate, and above the sixth, have generally comprehended under the general name of frigates, and never appear in the line of battle. They are divided into the fifth and sixth rates: the former mounting from 50 to 52 guns, and the latter from 28 to 30. The largest of the fifth rate have two decks of cannon, the lower battery being of 18-pounders, and that of the upper-deck of 9-pounders; but those of 30 and 32 guns have one complete deck, mounting 12-pounders, besides the quarter-deck and forecastle, which carry 6-pounders. The complement of a ship of 44 guns is 250 men; and that of a frigate of 36 guns, 240 men. The first has three, and the second two lieutenants; and both have two master's-mates, six midshipmen, two surgeon's-mates, six quarter-masters and their mates, two boatswain's-mates and one yeoman, one gunner's mate and one yeoman, with 10 or 11 quarter-gunners, and one purser's steward.

Frigates of the 6th rate carry 9-pounders, those of 28 guns having 3-pounders on their quarter-deck, with 200 men in attendance; and those of 24, 100 men: the former have two lieutenants, the latter one; and both have two master's-mates, four midshipmen, one surgeon's-mate, four quarter-masters and their mates, one gunner's-mate, one yeoman, one gunner's-mate and one yeoman, with six or seven quarter-gunnery, and one purser's steward.

The sloops of war carry from 18 to 8 cannon; the largest have six-pounders; and the smallest, viz. those of 8 or 10 guns, four-pounders. Their officers are generally the same as in the 6th rate, with little variation; and their complement of great delays is to keep the officers to the force or magnitude. Bomb-vessels are on the same establishment as sloops; but fire-ships and hospital ships are on that of fifth rates.

The first rates, which have two tiers, are fit for the line of battle, to lead the convoys and squadrons of ships of war in action, and in general to suit the different exigencies of the naval service. The fourth rates may be employed on the same occasions as the third-rates, and may be also destined amongst the foreign colonies, or on expeditions of great delay; for these ships are excellently useful for keeping and sustaining the sea. Vessels of the fifth rate are too weak to suffer the shock of a line of battle; but they may be designed to lead the convoys of merchant-ships, to protect the commerce in the colonies, to cruise in different stations, to accompany squadrons, or be sent express with necessary intelligence and orders. The same may be observed of the sixth-rates. The frigates, which mount from 28 to 33 guns upon one deck, with the quarter-deck, are extremely proper for cruising against privateers, or for short expeditions, being light, long, and usually excellent sailers.

RATEEN, in commerce, a thick woollen stuff, quilted, woven on a loom with four threads, like serge, and other stuffs, that have the scale or quilted appearance. There are some rateens dressed and prepared like cloths; others left simply in the hair, and others where the hair or knap is fried.

RATIO, in mathematics and geometry, is that relation of homogeneous things which determines the quantity of one from the quantity of another, without the intervention of a third.

Two numbers, lines, or quantities, A and
B, being proposed, their relation one to another may be considered under one of these heads: 1. How much A exceeds B, or B exceeds A; and this is found by taking A from B or B from A, and is called arithmetical reason, or ratio. 2. Or how many times, and parts of a time, A contains B, or B contains A; and this is called geometric reason or ratio; or, as Euclid defines it, it is the mutual habit, or respect, of two magnitudes of the same kind, according to quantity; that is, as to how often the one contains, or is contained in, the other; and is found by dividing A by B, or B by A; and here note, that ratio which quantity is referred to another quantity, is called the antecedent of the ratio; and that to which the other is referred, is called the consequent of the ratio; as, in the ratio of A to B, A is the antecedent, and B the consequent. Therefore any quantity as antecedent, divided by any quantity as a consequent, gives the ratio of that antecedent to the consequent.

Thus the ratio of A to B is \( \frac{a}{b} \), but the ratio of B to A is \( \frac{b}{a} \); and, in numbers, the ratio of 12 to 4 is \( \frac{12}{4} = 3 \), or triple; but the ratio of 4 to 12 is \( \frac{4}{12} = \frac{1}{3} \), or subtriple.

The quantities thus compared must be of the same kind; that is, such which, by multiplication, may be made to exceed one the other; or as these quantities expressed to have a ratio between them, which, being multiplied, may be made to exceed one another. Thus a line, how short soever, may be multiplied, that is, produced so long as to exceed in length any given right line; and consequently these may be compared together, and the ratio expressed; but as a line cannot, by any multiplication whatever, be made to have breadth, that is, to be made equal to a superficies, how small soever; these cannot therefore be compared together, and consequently have no ratio or respect one another, according to quantity; that is, as to how often the one contains, or is contained in, the other. See PROPORTION.

RATIO, a certain allowance which is given in bread, &c., or forage, when troops are reliefed. See an officer or soldier.

Complete ratio of the small species.

When the small species are not issued, 1½ lbs. of flour or bread, with 1½ lbs. of beef, or 10 oz. of pork, forms a complete ratio; or 3 lbs. of beef, or 2 lbs. of cheese, or half a pound of rice, forms a complete ratio.

The deductions to be taken for provisions from the pay of officers, non-commissioned officers, or men, are the same for all ranks, and in all corps, and—like the circumstances of service, when serving out of Great Britain, or stations where provisions are supplied by the public; also, when embarked in transports or other vessels, (except when serving as marines;) also when prisoners of war, maintained at the expense of Great Britain; also when in general hospitals, whether at home or abroad, a deduction of sixpence per day.

A deduction of threepence halfpenny from the pay of every non-commissioned officer and private in Jamaica, in New South Wales, or Gibraltar.

Non-commissioned officers and soldiers serving as marines shall not be liable to any deduction from their full pay on account of their war service.

Ration for a horse on home service in 1795, 14 lbs. of hay, 10 lbs. of oats, 4 lbs. of straw, for which a stoppage is made of sixpence.

The French use the same term, viz. ration de foin, a ration of hay; double ration, double ration; demi-ration, a half ration.

RATIONAL is applied to integral, fractional, and mixt numbers; thus we say, rational fraction, rational integer, and rational mixt number.

Rational is applied to the true horizon, in opposition to the sensible or apparent one. RATIONALS, a solution, or account of the principles of some opinion, action, hypothesis, plan, or the like.

RATLINES, or, as the seamen call them, Ratlines, those lines which make the ladder-steps to go up the shrouds and futtocks, hence called the ratlines of the shrouds.

RATTLE-SNAKE. See Crotalops.

RAVEN, in fortification, was a flat bastion, placed in the middle of a curtin; but now a detached work composed only of two faces, which make a salient angle, without any flanks, and raised before the curtin on the common face of the place. A ravelin is a triangular work resembling the point of a bastion with the flanks cut off. See FORTIFICATION.

In use before a curtin is, to cover the opposite flanks of the two next bastions. It is used also to cover a bridge, or a gate, and is always placed without the moat. There are also double ravelins that serve to cover each other; they are said to be double when they are joined by a curtin.

RAVEN. See Corvus.

RAUWOLFIA, a genus of the pentandria monogynia class of plants, the corolla of which consists of a single funnel-shaped petal, with a large limb, divided into five inclosed segments; the fruit is a succulent berry, with five seeds. There are four species, trees of South America.

RAY, a beam of light emitted from a radiant or luminous body. See OPTICS.

RAYS OF LIGHT, colour and heat of. Dr. Herschel had been employed in making observations on the sun by means of telescopes. To prevent the inconvenience arising from the heat, he used coloured glasses; but these glasses, though deep enough, colored to intercept the light, very soon cracked and broke in pieces. This circumstance induced him to examine the heating power of the different coloured rays. He made each of them turn upon the bulb of a thermometer, near which two other thermometers were placed to serve as a standard. The number of degrees which the thermometer exposed to the coloured ray rose above the other, which were kept under the heating power of that ray. He found that the most refrangible rays have the least heating power; and that the heating power gradually increases as the refrangibility decreases.

The violet ray therefore has the smallest heating power, and the red ray the greatest. Dr. Herschel found that the heating power of the violet, green, and red rays, are to each other as the following numbers: Violet = 1, Green = 22.4, Red = 55.

It struck Dr. Herschel as remarkable, that the illuminating power and the heating power of the rays follow different laws. The first is in greatest perfection in the middle of the spectrum, and diminishes as we approach either extremity; but the second increases constantly from the violet end, and is greatest at the red end. This led him to suspect that perhaps the heating power does not stop at the end of the visible spectrum, but is continued beyond it. He placed the thermometer completely beyond the boundary of the red ray, but still in the line of the spectrum, and found it still higher than it had done when exposed to the red ray. On shifting the thermometer still farther, it continued to rise; and the rate did not reach its maximum till the thermometer was half an inch or more beyond the situation of the red ray. When shifted still farther, it sank a little; but the power of heating was sensible at the distance of 1½ inch from the red ray.

These important experiments have been lately repeated and fully corroborated by Sir Henry Englefield, in the presence of some very good judges. The apparatus was very different from that of Dr. Herschel, and confided on purpose to obviate certain objections which had been made to the conclusions drawn by that illustrious philosopher. The bulbs of the thermometers used were mostly blackened. The following table exhibits the result obtained in one of these experiments:

<table>
<thead>
<tr>
<th>Thermometer in the blue ray rose in</th>
<th>3' from 55° to 50°</th>
</tr>
</thead>
<tbody>
<tr>
<td>green</td>
<td>3°</td>
</tr>
<tr>
<td>yellow</td>
<td>3°</td>

Both Dr. Herschel and Sir Henry Englefield take notice of a faint blush of red at a semi-oval form, visible when the rays beyond the red end of the spectrum were collected by a lens.

From these experiments it seems to follow, that there are rays emitted from the sun, which produce heat, but have not the power of illuminating; and that these are the rays which produce the greatest quantity of heat. Consequently color is emitted from the sun.
in rays, and the rays of caloric are not the same as the rays of light. 1. On examining the other extremity of the spectrum, Dr. Herschel ascertained that no rays of colored heat and of violet ray. He had found, however, as Sen- nebier had done before him, that all the coloured rays of the spectrum have the power of heating; it may be questioned therefore whether there are any rays which do not warm. The coloured rays must either have the property of exciting heat as rays of light, or they must derive that property from a mixture of rays of caloric. If the first of these suppositions was true, light ought to excite heat in all cases; but it has been long known to philo-

sophers that the light of the moon does not produce the least sensible heat, even when concentrated so strongly as to surpass, in point of illumination, the brightest candles or lamps, and yet these produce a very sensible heat. Here then are rays of light which do not produce heat; rays, too, composed of all the seven prismatic coloured rays. We must conclude, therefore, that the well-known fact, that rays of light do not excite heat; and consequently that the coloured rays from the sun and combustible bodies, since they excite heat, must consist of a mixture of rays of light and caloric. This case was demonstrated long ago by Dr. Hooke, and afterwards by Scheele, who separated the two species from each other by a very simple method. If a glass mirror is held before a glowing fire, the heat, but not the rays of caloric; a metallic mirror, on the other hand, reflects both. The glass mirror becomes hot; the metallic mirror does not alter its temperature. If a plate of glass is suddenly interposed between a glowing fire and the face, it intercepts completely the warming power of the fire, without causing any sensible diminution of its brilliancy; consequently it intercepts the rays of caloric, but allows the rays of light to pass. If the glass is allowed to remain in its station till its temperature has reached its maximum, in that situation it ceases to intercept the rays of caloric, but allows them to pass as freely as the rays of light. This case was demonstrated by Dr. Robison, professor of natural philosophy in the university of Edinburgh. The fact consists in this, viz., that the rays of light and of caloric are different, and that the coloured rays derive their heating power from the rays of caloric which they contain. Thus it appears that solar light is composed of three sets of rays, the colorless, the caloric, and the de-

oxidizing.

The rays of caloric are refracted by trans-
parent bodies just as the rays of light. We see, too, that, like the rays of light, they differ in their refrangibility: that some of them are as refrangible as the violet rays, but that the greater number of them are less refrangible than the red rays. Whether they are trans-
mitted through all transparent bodies has not been ascertained, but there is no difference of their refraction in different mediums been examined. We are certain, however, that they are transmitted and refracted by all transparent bodies which have been employed as birefringent substances, and have been proved, by experiment, that it is not only the
colorable emitted by the sun which is refrang-

ible, but likewise the rays emitted by common fires, by candles, by hot iron, and even by water.

The rays of caloric are reflected by polished surfaces in the same manner as the rays of light. This was lately proved by Herschel; but it had been demonstrated long before by Scheele, who had even ascertained that the angle of their reflection is equal to the angle of their incidence. Mr. Pictet also had made a set of very ingenious experiments on this subject, about the year 1790, which led to the same conclusion. He placed two convex mirrors of tin, of nine inches focus, at the distance of twelve feet two inches from one another. In the focus of one of them he placed a ball of iron two inches in diameter, heated so as not to be visible in the dark; in the other was placed the bulb of a thermometer. In six minutes the ther-
mometer rose 22°. A lighted candle, which was substituted for the ball of iron, produced nearly the same effect. In this case both the rays had to pass in order to separate them; he interposed between the two mirrors a plate of clear glass. The ther-
mometer sunk in nine minutes 14°; and when the glass was again removed, it rose in seven minutes 11°. This effect fell on the thermometer did not seem at all dimin-

ished by the glass. Mr. Pictet therefore concluded, that the caloric had been reflected by the mirror, and that it had been the cause of the temperature, and that a third experiment, a glass matrasst was substituted for the iron ball, nearly of the same diameter with it, and containing 2043 grains of boiling water. Two minutes after a thick screen of silk, which had been interposed between the two mirrors, was removed, the thermometer rose from 47° to 50°, and descendent again the moment the matrasst was removed from the focus.

The mirrors of tin were now placed at the distance of 93 inches from each other; the matrasst with the boiling water in one of the, and a very sensible air thermometer in the other, every degree of which was equal to half a degree Fahrenheit. Exact-

ly in the middle space between the two mirrors there was placed a very thin common glass mirror, suspended in such a manner that either side could be turned towards the matrasst. In the mean time of this mirror was turned to the matrasst, the thermometer rose to 3.5°. In another experiment, when the polished side of the mirror was turned to the matrasst, the thermometer rose 3°, when the other side the same. On rubbing off the tin foil, and repea-
ting the experiment, the thermometer rose 0.5°. On substituting for the glass mirror a piece of thin white pasteboard of the same dimensions with it, the thermometer rose 10°. As the rays of light and of caloric emitted the sun accompany each other, it cannot be doubted that they move with the same velocity. The rays of caloric, therefore, move at the rate of almost 500,000 miles in a second. This is confirmed by an experiment of Mr. Pictet, which he performed in the following manner: He took a glass globe three inches in diameter, with a short neck, and weighing 451 grains; poured into it 1700 grains of water from the New River, London, and then sealed it hermetically. The whole weighed 2150.5 grains at the temperature of 32°. It was put for twenty minutes into a freezing mixture of snow and salt, till some of it was frozen; it was then, after being wiped first with a dry linen cloth, next with clean washed dry leather, immediately weighed, and found to be 22° below the weight of a grain heavier than before. This was repeated exactly in the same manner five different times; at each, more of the water was frozen, and more weight gained. When the whole water was frozen, it was 30° of a grain heavier than it had been when fluid. A thermometer applied to the glass showed at 10° the temperature of the air; when the thermometer was put into a glass globe in the same manner, the same column of the thermometer rose to 32°; it weighed 30° of a grain more than it did at the same temperature when fluid. It will be seen afterwards, that ice contains less caloric than water of the same temperature with it. The balance used was nice enough to mark 1° with part of a grain.

This subject had attracted the attention of Lavoisier, a philosopher distinguished by the uncommon accuracy of his researches. His experiments, which were published in the Memoirs of the French Academy for 1783, led him to conclude that the phenomena of water, when placed on the face of the tin mirror there was placed a thick screen, which was removed as soon as the bullet reached the focus. The thermometer rose the instant the screen was removed, and remained without. Any heat, consequently the time which caloric takes in moving 60 feet is too minute to be measured. We see at once that this must be the case when we recollect that caloric moves at the rate of 500,000 miles in a second.

The velocity of caloric being equal to that of light, its particles must move in an equally minute. Therefore neither the addition of caloric nor its abstraction can sensibly affect the weight of bodies. As this follows necessarily as a consequence from Dr. Herschel's experiments, it was possible to prove by experiment that caloric affects the weight of bodies, the theory founded on Dr. Herschel's discoveries would be overturned: but such ded-

uctions have been drawn from the experiments of De Luc, Fordyce, Moreau, and Chauvier. According to this view, the bodies become absolutely lighter by being heated. The experiment of Fordyce, which seems to have been made with the greatest care, was conducted in the following manner:

He took a glass globe three inches in diameter, with a short neck, and weighing 451 grains; poured into it 1700 grains of water from the New River, London, and then sealed it hermetically. The whole weighed 2150.5 grains at the temperature of 32°. It was put for twenty minutes into a freezing mixture of snow and salt, till some of it was frozen; it was then, after being wiped first with a dry linen cloth, next with clean washed dry leather, immediately weighed, and found to be 22° below the weight of a grain heavier than before. This was repeated exactly in the same manner five different times; at each, more of the water was frozen, and more weight gained. When the whole water was frozen, it was 30° of a grain heavier than it had been when fluid. A thermometer applied to the glass showed at 10° the temperature of the air; when the thermometer was put into a glass globe in the same manner, the same column of the thermometer rose to 32°; it weighed 30° of a grain more than it did at the same temperature when fluid. It will be seen afterwards, that ice contains less caloric than water of the same temperature with it. The balance used was nice enough to mark 1° with part of a grain.

This subject had attracted the attention of Lavoisier, a philosopher distinguished by the uncommon accuracy of his researches. His experiments, which were published in the Memoirs of the French Academy for 1783, led him to conclude that the phenomena of water, when placed on the face of the tin mirror there was placed a thick screen, which was removed as soon as the bullet reached the focus. The thermometer rose the instant the screen was removed, and remained without. Any heat, consequently the time which caloric takes in moving 60 feet is too minute to be measured. We see at once that this must be the case when we recollect that caloric moves at the rate of 500,000 miles in a second.
Caloric not only possesses the velocity of light, but agrees with it also in another property no less peculiar. Its particles are not exactly the same size, but are colloidal in mass; and whenever they are forcibly accumulated, they fly off in all directions, and separate from each other with inconceivable rapidity. This property necessarily suppose the existence of a mutual repulsion between the particles of caloric.

Thus it appears that caloric and light resemble each other in a great number of properties. Both are emitted from the sun in rays, with the velocity of 200,000 miles in a second; both of them are refracted by transparent bodies, and reflected by polished surfaces; both of them consist of particles which mutually repel each other, and which produce no sensible effect upon the weight of other bodies. They differ, however, in this particular, light produces in us the sensation of vision; caloric, on the contrary, the sensation of heat.

Upon the whole, we are authorized by the above statement of facts, to conclude that the solar heat is composed of three distinct substances, in some measure separable by the prism on account of the difference of their refrangibility. The caloric rays are the least refrangible, the deoxidizing rays are most refrangible, and the caloric rays possess a mean degree of refrangibility. Hence the rays in the middle of the spectrum have the greatest illuminating power, those beyond the red end the greatest heating power, and those beyond the violet end the greatest deoxidizing power: and the heating power on the one hand, and the deoxidizing power on the other, gradually increase as we approach that end of the spectrum where the maximum of each is concentrated. These different bodies resemble each other in so many particulars, that the same reasoning respecting refrangibility, reflectibility, &c. may be applied to all of them. They produce different effects upon those bodies on which they act. Little progress has yet been made in the investigation of these effects; but we may look forward to this subject as likely to correct many vague and unmeaning opinions which are at present in vogue among philosophers.

**REALGAR.**

Reach, in the sea language, signifies the distance between any two points of land, lying nearly in a right line.

Re-action, in physiology, the resistance made by all bodies to the action or impulse of others, that endeavour to change its state whether of motion or rest. See MOTION.

**REALGAR.**

Realgar, a mineral found in Sicily and various parts of Germany. It is either massive or crystallized. The primitive form of the crystals of iron with scalenohedrals, and it commonly appears in 4, 6, 8, 10, or 12 sided prisms, terminated by four-sided pyramids. Colour red. Streak yellowish-red. Specific gravity 3.355. It is electric on anode, and becomes incandescent electric by rubbing. Before the blowing of the wind, it easily burns with a blue flame, and soon evaporates. It is also the old name for a sublimate of arsenic, found native in different parts of Europe. It has a scarlet colour, and is usually found in transparent prisms. Its specific gravity is 3.5. It is composed of 50 parts of arsenic, and 20 of sulphur, and it is sometimes used as a part.

Rea, a term frequently used in composition, to denote something behind, or back of, another; thus, the back of a chair or sofa, in opposition to its front; thus, neo-classical, if used for the back part of a building, in opposition to the front, for the rear-guard, rear half-sheets, rear-line, rear-rank, and rear-admiral.

**REALM OF THE PROVINCE OF THE BADGERS.**

This is a second attack of a bear that was formerly attacked and dismissed the court without day, as by the not coming of the justices, or some such cause.

**REALMURIA.**

A genus of the class order polyandria pentagonia. The calyx is six-leafed; petals five; caps one-celled, five-valved, many-seeded. There is one species, an annual of Egypt.

**REAL-REBUTTER.**

In commerce, a term much used at Amsterdam, for an abatement in the price of several commodities, when the buyer, instead of taking time, advances ready money.

**REAL-REBUTTER.**

In commerce, a term much used at Amsterdam, for an abatement in the price of several commodities, when the buyer, instead of taking time, advances ready money.

**REBUTTER.**

Is the answer of the defendant to the plaintiff's sur-rejoinder.

**RECAPITULATION.**

In oratory, _&c._ is a summary, or a concise and rapid enumeration, of the principal things insisted on in the preceding discourse, whereby the force of the whole is collected into one view.

**RECAPITULATION.**

Where one has deprived another of property, the owner may lawfully claim and retake it wherever he happens to find it, so that it shall not be in a riotous manner, or attended with any breach of the peace.

RECEIPTS, are acknowledgments in writing of having received a sum of money or other value. A receipt is either a voucher for an obligation discharged or one incurred. Receipts for money above 40s. must be stamped; but on the back of a bill of exchange or promissory note which has already stamp'd, is good without a farther duty. Writing a receipt on a stamp of greater value than the value requires, inures no penalty, and the receipt is taken off on a stamp of a lower value, or on unstamped paper, then a receipt is no discharge, and incurs a penalty. See STAMP.

**RECEIVER.**

In Pneumatics, a glass vessel for containing the thing on which an experiment in the air-pump is to be made.

**RECEIVER.**

In chemistry, a vessel of earth, glass, &c. for receiving any distill'd liquor.

**RECEIVER.**

Receiving stolen goods, know'n to be stolen, is a high misdemeanor at the common law; and by several statutes is made felony and transportation; and in some particular instances, felony without benefit of clergy.

**RECEIVER.**

Also signifies an officer, of which there are several kinds, denominated from the particular matters they receive, the places where, or the persons from whom, &c.

**RECEIVER.**

Is an officer appointed to receive the money of such persons as are in compend with the king, upon original writs sued out of ohanancy. 2. Receiver-general of the duchy of Lancaster is an officer belonging to the duchy-court, who collects the revenues, fines, forfeitures, and assessment s, within that duchy. 3. Receiver-general of the public revenue, is an officer appointed in every county, to receive the taxes granted by parliament, and remit the money to the treasury.

**RECIPE.**

In medicine, a prescription or remedy, to be taken by a patient; so called because it is written with the word recipi, i.e. take; which is generally denoted by the abbreviation _R._

**RECIPIENT, or RECIPIENT.**

A mathematical in-trument, serving to measure re-entering and salient angles, especially in fortifications.

It usually consists of two arms, or rulers, AC, and BC (Plate Misc. fig. 197) riveted together at C, and capable of being opened and closed, like a sector. To take an angle with it, they lay the centre of a protractor over the joint C, and apply its diameter to one of the rulers; then the degrees cut by the edge of the other ruler, show the quantity of the angle.

There are other forms of this instrument: the _M._ (figured 198), has a graduated circle, by which may be readily measured by its index; and fig. 199. is another kind composed of four equal rulers of brass, riveted together by their ends, so as to form a parallelogram; and on one of the rulers, which is a graduated semicircle, which measures the opposite angle of the parallelogram, by means of one of the rulers produced so as to serve instead of an index.

**RECIPROCAL TERMS, among logicians, are those figures which have the antecedents and consequents of the same ratio, in both figures.**

Thus, (Plate Misc. fig. 200.) A:B::C:D or 12:4::3:9; that is, as much as the side A, in the first rectangle, is longer than B, so much deeper is the side C, in the second rectangle, than the side D in the first; and, consequently, the greater length of the one is compensated by the greater breadth or depth of the other; for the side A is 3 longer than C, so B is 4 longer than D, and the two are equal, so that A + D = B + C, or 12 3 = 4 9 = 36.

This is the foundation of that capital theorem, viz., that the rectangle of the extremes is always equal to that of the means; and, consequently, the reason of the rule of three.

Hence it follows, that if any two triangles, parallelograms, prisms, parallelepipeds, pyramids, cones, or cylinders, have their bases and altitudes reciprocally proportional, those two figures are equal to each other; and, vice versa, if they are equal, then their bases and altitudes are reciprocally proportional. See TRIANGLE, PARALLELOGRAM, &c.

**RECIPROCAL PROPORTION, in arithmetic, is when, in four numbers, the fourth is less than the second, by so much as the third is greater than the first; and vice versa.

This is the foundation of the inverse, or indirect, rule, which is fixed a graduated semicircle, 4: 10 = 8: 5. It is applied also to quantities which, being multiplied together, produce unity. Thus 1 and x, y and 1, are reciprocal quantities, be-
RECOGNISANCE, or RECOGNIZANCE, is an obligation of bond, which a man enters into before some court or record, or magistrate duly authorized, with consent given to some particular act; to appear at the assize or quarter sessions, to keep the peace, &c.

RECOIL, or REBOUND, the starting backward of a firearm, after an explosion. Merriam tells us, that a cannon 18 feet in length, weighing 8400 lb. gives a ball of 24 lb. an uniform velocity of 640 feet per second. Parting, therefore, \( w = 8400 \), \( w = 24 \), \( v = 640 \), and \( \omega = \frac{v}{w} = \frac{24 \times 64}{8400} = 0.24 \); that is, it could recoil at the rate of 2.2 feet per second free to move.

RECORD, An act committed to writing in any of the king's courts, during the term wherein it is written, is alterable, being no bond; but that term, the contrary, it is a record, and of that which consists of no alteration or proof of the contrary.

RECORDARE FACIAS, a writ directed to the sheriff, to remove a cause out of an inferior court, into the king's bench or common pleas.

RECORER, a person whom the mayor or other magistrates of a city or corporation nominate to them, for their better direction in matters of justice, and proceedings in law; and which account this person is generally a learned, or well skilled in the law. The recorder of London is chosen by the lord-mayor and aldermen; and, as he is led to be the mouth of the city, he delivers judgment of the courts, and records judgments.

RECOVERY, in law, is obtaining anything by judgment or trial at law. A recovery resembles a fine so far as being action red or fictitious, and in that land are recovered against the tenant of the freehold, and an absolute fee-simple is vested in the recoveror; but it is carried through every stage of proceeding, instead of being compromised like a fine. See Fine.

This invention we owe to the ingenuity of the ecclesiastics, to evade the statute of mortmain, which prohibited, without licence, any giving or receiving, under pretence of a free gift, or any lands or tenements whatsoever; and as judgment was given for religious houses, they were presumed to have recovered the lands by sentence of law on a supposed prior title, and were held not to recover in the statute.

The convenience of these recoveries was soon discovered, and made use of by lay persons as a common mode of transferring lands; but the want of moderation on the part of the ecclesiastics, in their frequent recourse to feigned recoveries, was such as to call for parliamentary interference, and gave rise to the act in the reign of Edward the First, called the statute of Westminster; which enacted, that in all cases where any recoveries were made to lay persons, the lands so recovered by default, a jury should try the right; and if the defendants were found to have no title, the land should be forfeited to the lord of the fee, according to the statute of mortmain.

This act threw the recoveries into disuse, till they were resumed as a mode of evading the strictness of the statute de donis conditionibus, which lays a general restraint on alienations, but allows many at-tempts to procure a release of this statute; but in vain: but as the inconveniences were manifest, the judges always endeavoured to construe means of evading it; and it was decided in a case in the reign of Edward IV., that a common recovery suffered by a tenant in tail, should operate as an effetual bar to his estate tail, and to all remainders and reversioners depending thereon; by which means tenants in tail are now enabled to dispose of their estates, or convert them into estates in fee-simple; and it may be suffered of all things, whereof a writ of covenant may be brought for the purpose of levying a fine.

There are three persons required to form a recovery: the demandant, tenant, and vouchee. The demandant is he who brings the writ of entry; the tenant is he against whom the writ is brought; and the vouchee is he whom the tenant vouches and calls to warranty; but this may be better understood by supposing John Jacobs to be tenant of the freehold, and desires of recovering a recovery to cut off all entail and reversions, and to convey the estate in fee-simple to James Jenkins. Jenkins sets out a writ of recovery, and, by him, as in the case of a fine, and charges that the defendant has no title, but came into possession after Hugh Hunt had turned the plaintiff out of it. The proceedings are made up on the recovery-roll, in which the writ and complaint of the defendant are recited; the tenant then apprises and calls upon one Charles Browning, who is supposed at the original purchase to have warranted the title to the tenant, and who is supposed to vouch; the vouchee then appears, is impleaded, and defends the title. Jenkins, the defendant, craves leave to impri, which is granted; the plaintiff then returns into court, but the vouchee is arraigned, and makes default; judgment is of course given for Jenkins, and Jacobs is to recover the value of Charles Browning, as he lost them through his default. But on enquiry, it is always found that Browning (who is merely an officer of the court, and denominated the common vouchee, from being impri, at whatever, has no lands, so that Jacobs, now vouching the recoveror, has but a nominal recompense; and the plaintiff, who is now recoveror, has the lands vested in him by judgment of the court, and again delivered by the sheriff. A recovery is sometimes with double or treble voucher, or even more if necessary. And, indeed, a double voucher is the most common, by first conveying an estate to any third person, against whom the writ is issued, he then vouches the tenant in tail, who vouches over the common vouchee; for if the recovery is had immediately against the tenant in tail, it bars only such estate in the premises of which he is then actually seized; but the act of error must be brought during his minority.

Sometimes, though but seldom, the court permits the infant to appear by guardian, where the recovery is made in manor advantage to the infant; and when this has been allowed by the judges, the infant cannot set it aside; but if it is to the prejudice of the infant, he has a remedy by action against the guardian. This appeared in several cases. If the infant appears by attorney, he may recover the recovery after he is of age, because it may be here discovered by trial whether the warrant of attorney was made by him while an infant. A married woman joining with her husband in recovering a recovery, will bar her remainder; because as she is examined privately as to her consent, it takes away the presumption in law that it is done by the consent of her husband. All persons have power to sue a recovery except the king, and for his use, or where the plaintiff must count against him, which the law does not allow, infants, persons non compos, and women who are personal dower; who are prohibited by the statute of Henry VII. c. 20, which enacts that a recovery suffered by any woman of lands settled by her on her husband, or settled on her husband and her by any of his ancestors, shall be void.

The effect of common recoveries may appear to be an absolute bar of all estates, if, but of remainders and reversions expectant on the determination of such estates. Sol that a tenant in tail may convey lands in tail to the recoveror, free and discharged of all conditions and appointments in tail, and of all remainders and reversions. But as before mentioned, a woman possessed of dower is prevented by the statute; and by the statute of Eliz. c. 8, no tenant for life of any sort can suffer a recovery, so as to bind the remainders or reversion. For which reason, if there is a tenant for life with remainder in tail, and other remainders in tail, and the tenant for life is desirous to suffer a valid recovery, either he or the tenant to the precise should vouch the remainder-man in tail. It is an essential part of a recovery, that the tenant to the precise should be actually
seized of the freehold; but by 14 Geo. II. though the legal freehold should be vested in lessees, yet those who are intitled to the next freehold estate in remainder or reversion may make a good tenant to the precise; and though the deed or fine which creates such tenant should be subsequent to the judgment of recovery, if it is in the same term, the recovery is valid; and that though the recovery itself does not appear to be entered, or not regularly entered on record; yet she dued to make a tenant to the precise and declare the uses of the recovery, with twenty years possession, shall be sufficient evidence of the recovery. If a recovery is levied without good title, the good title is determined, and the uses declared, they only oure to the uss of him who levies them; and if there is a consideration, yet as the most usual use, sur cognizance de droit, and c. c. conveys an absolute estate without limitations, these conveyances could not be made to answer the purposes of family, settlements (wherein a variety of uses and designations is often necessary), unless their force and effect were made subject to the direction of more complicated deeds. These deeds, if made previous to the judgment, are called deeds to lead the uses; if subsequent, to declare them.

RECTANGLE, in geometry, the same with a right-angled parallelogram.

RECTANGLED, RECTANGULAR, or RIGHT-ANGLED, appellation given to figures and solids which have one or more right angles: thus a triangle with one right angle, is termed a rectangular triangle; also parallelograms with right angles, squares, cubes, &c. are rectangular. Solids, as cones, cylinders, &c. are also said to be rectangular with respect to their axes, when their axes are perpendicular to the plane of the horizon.

RECTIFICATION, in geometry, is the finding a right line, equal in length to a curve. See the article CURVE.

The rectification of curves is a branch of the higher geometry, where the use of the inverse method of fluxions is very conspicuous.

Case I. Let AC, (Plate Six, fig. 201) be any kind of curve, whose ordinates are parallel to themselves, and perpendicular to the axis AQ. Then if the fluxion of the absciss AM be denoted by Ma, or by Ca (equal and parallel to Ma), and a", equal and parallel to Ca, is the representation of the corresponding fluxion of the ordinate MC; then will the diagonal CS, touching the curve in C, be the line which the generating point p would describe, was its motion to become uniform at C; which line, therefore, truly expresses the fluxion of the space AC, gone over. See the article Fluxions.

Hence, putting AM = a, CM = y, and AC = a'; we have a = dy = \sqrt{Ca^2 + Sa^2} = \sqrt{a^2 + y^2}, from which, and the equation of the curve, the value of y may be determined. Thus, let the curve be represented by a parallelogram of any kind, the general equation for which is 

\[ a \times y = 0 \]

and hence \( a = \frac{n - 1}{y} \), and therefore

\[ \frac{n}{a^2} \]

and the result is

\[ \frac{\sqrt{1 + \frac{n}{a^2}^2}}{a^2} = \sqrt{\frac{\frac{n}{a^2} + \frac{2n - 2}{a^2}}{2}} \]

which lies for a woman who has received part of her dower, and purposes to demand the remainder in the same term, against the heir, or his guardian.

RECTO D OE DOTE UNDE NIEL HARTE, a writ of right which lies in a case, where the husband having divers lands or tenements, has assured no dower to his wife, and she thereby is driven to sue for her thirds, against the heir or his guardian.

RECTO QUANDO DOMINUS REMISET, a writ of right, which lies in cases, where lands or tenements in the seignory of any lord are in demand by the right of the tenant.

RECTOR, a term applied to several persons whose offices are very different; as 1. The rector of a parish is a clergyman who has the charge and cure of a parish, and possesses all the tithes, &c. 2. The same name is also given to the chief elective officer in several foreign universities, particularly in that of Paris. 3. Rector is also used in several convents for the superior officer who governs the house; and the Jesuits give this name to their superiors of such houses as for other seminaries or colleges.

RECTORY, a parish church, parsonage, or spiritual living, with all its rights, tithes, and glebes.

RECTUM, in anatomy, the last and third part of the large intestines. See Anatomy.

RECURVIROSTRA, in ornithology, a genus belonging to the order of grallae. The bill is long, subulate, bent back, sharp and narrow; the legs are webbed, and furnished with three toes forwards, and one short behind. Mr. Latham notes of this genus three species, viz. the avocet, or the one commonly known, the American, and the alba. This last, it is probable, has some affinity to the American. The recurvirostra avocetta is about the size of a lapping body, but has very long legs. The substance of the bill is soft, and almost membranous at its tip, it is thin, weak, slender, compressed horizontally, and incapable of defence or effort. These birds are variegated with black and white, and during the winter are frequent on the eastern shores of Great Britain. They visit the Severn, and sometimes the pools of Shropshire. They feed on worms and insects, which they scoop out of the sand with their bills. They lay two eggs, white, with greenish lustre, and large spots of black, about the size of a pigeon's. They are found also in various parts of the continent of Europe in Russia, Denmark, and Sweden, but they are not numerous. They are also found in Siberia, but offenier about the salt lakes of the Tartar desert, and about the Caspian sea; likewise on the coasts of Picardy, France, in April and November, and at Orleans, but rarely. In breeding-time they are very plentiful on the coasts of Bas Poison. They do not appear to wander further south in Europe than Italy. Whether from tempest or address, the avocet shuns shores, and is not easily taken. The American avocet is rather larger and longer than the last. The bill is similar, but thicker; the fore head dusky white; the head, neck, and upper part of the breast, are of a deep cream-colour; the lower parts of the neck behind white; the back is black; and the under parts from the pure wings are purplish black, rarely white, and partly ash-coloured. These birds inhabit North America; and were...
RED

found by Dampier in Shaks' bay, on the coast of New Holland. See Plate Nat, Hist. fig. 345.
The recrivostra, or sectopela alta, is about 14 inches and a quarter long, its colour white, with a patch of crimson on its keys duckish, its bill orange, its legs brown. Edwards remarks that the bill of this bird is bent upwards, as in the avost: its bill black at the tip, and orange at the rest of its length; all the plumage is white, except a tine of yellowish on the great quills of the wing and of the tail. Edwards supposes that the whiteness is produced by the cold climate of Hudson's-bay, from which he received it, and that they remain their brown for whatever during the summer. It appears that several species of this bird have spread further into America, and have even reached the southern provinces.

A bird of this kind, Mr. Latham says, was sent from Hudson's-bay, and from the figure, has any appearance of an avost. In Edwards's plate, however, the toes appear cluen to the bottom: a circumstance seeming to overturn the supposition, an I only to be authenticated when other specimens shall have come under the eye of the well-informed naturalist.

RECURSANT, a person who refuses to go to church, and worship God after the manner of the church of England, as by law established; to which is annexed the penalty of 20 l. a month for nonconformity. 32 Eliz. c. 1.

RED, in dyeing, is one of the five sines or other colours. See Dyeing.

RED-LEAD. See Lead, oxide of.

RED-book of the exchequer, an antient record or manuscript containing the publick accounts of the king's remembrancer, containing divers miscellaneous treatises relating to the times before the Conquest.

REDDENDUM, in our law, is used substantively for the cause in a lease wherein the rest is reserved to the lessor. The provisions for it is next after the limitation of estate.

REDEMPTION, in law, a faculty or right of reentering upon lands, &c. that have been sold and assigned, upon reimbursing the purchaser the purchase money with all legal costs. Bargains whereby the faculty, or, as some call it, the equity, of redemption is reserved, are only a kind of pignorative contracts. A certain time is limited within which the faculty of redemption shall be exerciséd, and beyond which it shall not extend.

REDENS, REDANS, or REDANT, in fortification, a kind of work indented in form of the teeth of a saw, with rampart and receding angles, to the end that one part may flank or defend another. It is called saw-work, and indented work. Redens are frequently used in the fortifying of walls, where it is not necessary to be at the expense of building stairs; as when they stand on the side of a river, a marsh, the sea, &c.

REDOUBT, or REDOUTE, in fortification, a small square fort, without any defence but in front, used in trenches, lines of circumvallation, and approach, as also for the lodgings of corps de garde, and to defend passages. In marshy grounds, redoubts are frequently made of stone-works, for the security of the neighbouring road; their face consists of 10 to 15 fathoms, the ditch round them from 8 to 9 feet broad and deep, and their parapets have the same thickness.

REDUCE, or REDUCE, a military term signifying an advantageous piece of ground, entrenched and separated from the rest of the place, camp, &c. for an army, garrison, &c. to retire in case of a surprize.

REDUCTION, that rule by which numbers or different denominations are brought into one denomination. See ARITHMETIC.

REDEMPTION, or Draught, or Draught, is the making a copy of it either larger or smaller than the original, still preserving the form and proportion. The great use of the proportional compasses is the reduction of figures, &c. whence they are called compasses of reduction.

There are various methods of reducing figures, &c. The most easy is by means of the pentagraph, or parallelogram; but this has its defects. See PENTAGRAPH.

The best and most usual methods of reductions are as follows: 1. To reduce a figure, as ABCDE (fig. 204). About the middle of the figure, as z, pitch a point, and from this point draw lines to its several angles A, B, C, &c. then drawing the line ab parallel to BC, be parallel to DC, &c. you will have the figure abcede similar to ABCDE.

If the figure abede had been required to be enlarged, there needed nothing but to produce the lines from the point beyond the angles, as zD, ZC, &c. and reduce the sides, viz. DC, CB, &c. parallel to the sides de, eb, &c.

2. To reduce a figure by the angle of proportion, suppose the figure ABCDE (fig. 204) required to be diminished in the proportion of the line AB to cb, (fig. 205). Draw the indefinite line GH (fig. 206) and from G to H set off the line AB. On G describe the arch HI. Set off the line ab as a chord on HI, and draw GJ. Then with the angle JGH, you have all the measures of the figure to be drawn. Thus, to lay down the point c, take the interval BC, and upon the point G, describe the arch KL. Also on the point G, describe MN: and upon A, with the distance MN, describe an arch cutting the one in c, which produce to the side bc. And after the same manner are the other sides and angles to be described. The same process will also serve to enlarge the figure.

3. To reduce a figure by a scale. Measure all the sides of the figure, as ABCDE, fig. 204, by a scale, and lay down the same measures respectively from a smaller scale in the proportion required.

4. To reduce a map, design, or figure, by squares. Divide the original into little squares; and divide a fresh paper of the dimensions required into the same number of squares, which are to be larger or less than the former, as the map is to be enlarged or diminished. This done, in every square of the second figure draw what you find in its correspondent one in the first.

REDUCTION, in metallurgy, is the bringing back metallic substances which have been vitiated or deformed, into their natural and original state of metals again. See CHEMISTRY.

Reduction, in surgery, denotes an operation by which a dislocated, luxated, or fractured bone, is restored to its former state or place.

REED, See Arundo.

REEF, a term in navigation. When there is a great gale of wind, they commonly roll up part of the sail below, that by this means it may become the narrower, and not draw so much wind; which contracting or taking up the sail they call a reef, or reeling the sail; so also when a top-mast is sprung, as they call it, that is, when it is cracked, or almost in the cap, they cut off the lower piece that was nearly broken off, and setting the other part, now much shorter, in the step again, they call it a reefed topmast.

REEL, in the manufactories. There are various kinds of reels, some very simple, others very complex. Of the former kinds those most in use are: 1. A little reel held in the hand, consisting of three pieces of wood, the biggest and longest wherein (which does not exceed a foot and a half in length, and a quarter of an inch in diameter) is traversed by two other pieces disposed differently. 2. The common reel, or windlass, which turns upon a pivot, and has four flights traversed by long pins or sticks, wherein the skin to be reeled is put, and which are drawn closer or opened wider according to the skin. A representation of the common reel may be seen in Plate Mixed, fig. 207, where A is the bench or seat of the reel, B the two uprights; C the arms of the reel, its anchor turning, and hitching its little lantern of four notches in the teeth of the wheel; D two handles, the upper one to make the lower by means of a pinion; E a hammer, the handle wherein is lowered by a peg at the bottom of the lower wheel; F a cord which is rolled round the axle of the lower wheel and supports a weight which stops after a certain number of turns, to regulate the work-woman.

REELING, in the manufactories, the winding of thread, silk, cotton, or the like, into a skin, or upon a bottom, to prevent its entangling. It is used for the charging or discharging of bobbins or quills, to use them in the manufacture of different stuffs, as thread, silks, cotton, &c.

RE-ENTRY, in law, signifies the resuming or retaining that possession which any one had before he was dispossessed; as where a person makes a lease of lands to another, the lessor thereby quits the possession, and the leasee covenants that upon non-payment of the rent reserved, the lessor may lawfully re-enter.

REEVING, in the sea language, the putting a rope through a block called a rope, or a piece of a block, is called unreeling.

REFINING, in general, is the art of purifying a thing: including not only the assaying or refining of metals, but likewise the de-
Refract, in astronomy, is the inclination of the rays of light proceeding from the heavenly bodies, in passing through the atmosphere, by which their apparent altitudes are increased. See Astronomy, Vol. I. page 171.

Reflection in a crystal,
REG

According to the establishment of the present French army, the term of regiment is confined to the space of thirty years, and the name of half-brigade is given to the infantry; so that chief de brigade, chief of brigade, corresponds with our colonel of a regiment of infantry. The denomination of colonel is still retained in the French cavalry.

With respect to the derivation of the word, it appears that the best etymology is from the French word regie, management, which comes from the Latin regere, to govern. Hence a regiment is said to be governed by a colonel. M. Lenentout, a celebrated French etymologist, differs from this explanation. He traces it from the French regime, which signifies system, regimen, administration, and which is again derived from the Latin regimen, bearing the same import. In a physical acceptance of the term, regimen (under regimen) is used to express any body that is composed of several others. But this is mere conjecture of his part.

REGISTER, a public book, in which are entered and recorded memos, acts, and minutes, to be had recourse to occasionally, for knowing and proving matters of fact.

Of these are two kinds; as 1. Registers of deeds in Yorkshire, and other ancient deeds, in which are registered all deeds, conveyances, wills, &c., that affect any lands or tenements in those counties, which are otherwise void against the subsequent purchasers, or mortgagees, &c., but this does not extend to any copyhold estate, nor to leases at a rack-rent, or where they do not extend beyond 150 years. The registered memorials must be registered under the seal of some of the grantees or grantees, attested by witnesses who are to prove the signing or sealing of them, and the execution of the deed.

But these registers which are confined to two counties, are in Scotland, general, by which the laws of North Britain are rendered very easy and regular. Of these there are two kinds; the one general, fixed at Edinburgh, under the superintendence of the law-register; and the other particular, in the several shires, warraceys, and regiments, the clerks of which are obliged to transmit the registers of their respective courts to the general register. No man in England can have a right to any estate, but it must be registered by the registrar thereof, day of his being seiz'd thereof, by which means all secret conveyances are cut off. 2. Parish registers, are books in which are registered the baptisms, marriages, and burials, of each parish. The dissenters of all denominations register the births of their children at Dr. Williams's Library in Red Cross street, Cripplegate.

REGISTER is also used for the clerk or keeper of a register. Of these we have several, denominated from the registers they keep; as register of the high court of delates; register of the arches court of Canterbury; register of the court of admiralty; register of the prerogative court; register of the garter, &c.

REGISTER SHIPS, in commerce, are vessels which obtain a permission either from the king of Spain, or the council of the Indies, to traffic in the Spanish and West Indies, which are thus called from their being registered before they set sail from Cadiz for Buenos Ayres. Each of these permissions costs 30,000 pieces of eight; and by the tenor of the edict, or permit, they are not to exceed 300 tons; but there is such a good understanding between the merchants and the council of the Indies, that ships of 5 or 60 tons frequently pass unnoticed; and though the quantity and quality of the merchandise on board are always expressed, yet by means of presents, the officers both in Spain and the Indies allow them to load and unload vastly more than the permission expresses.

REGISTER, in printing, is disposing the forms on the press, so that the lines and pages printed on one side of the sheet fall exactly on those of the other.

REGISTER, among letter-founders, is one of the inner parts of the mould in which the printing-types are cast. Its use is to direct the joining the mould justly together again, before it is opened to take out the new-cast letter.

REGLETS, or RIGLETS, in printing, are thin slips of wood, exactly planed to the size of the body of the letter. The smaller sorts are placed between the lines of poetry; and those that are used in filling up short pages, in forming the spaces or distances between the lines of titles, and in adjusting the distances of the pages in the chase so as to form register.

REGIMATOR, or REGIMATR, in law, formerly signified one who bought wholesale, or by the great, and sold again by retail; but the term is now used for one who buys any wares or victuals, and sells them again in the same market or fair, or within five miles round it. See FORESTALLING.

REGISTRAR, is also used for one who furnishes up old moveables to make them pass for new. And missus, who take off the outward surface of hewn stone, in order to whiten it, or make it look fresh again, are said to register.

REGULAR, denotes any thing that is agreeable to the rules of art: thus we say a regular building, verb, &c.

A regular figure in geometry is one whose sides, and consequently angles, are equal; and a regular figure with three or four sides, is commonly termed an equilateral triangle or square, as all others with more sides are called regular polygons.

All regular figures may be inscribed in a circle. A regular solid, called also a Platonic body, is that terminated on all sides by regular and equal planes, and whose solid angles are all equal.

The regular bodies are the five following: 1. The tetrahedron, which is a pyramid comprehended under four equal and equilateral triangles. 2. The hexahedron, or cube, whose surface is composed of the equilateral squares. 3. The octahedron, which is bounded by eight equal and equilateral triangles. 4. The dodecahedron, which is contained under twelve equal and equilateral pentagons. 5. The icosahedron, which is composed of twenty equal and equilateral triangles. These five are all the regular bodies in nature. See TETRAHEDRON, &c.

Proportion of the five regular bodies inscribed in the same (sphere) from Peter Hor- rigen. Cursus Math. vol. i. p. 773, and Bur- row's Euclid, lib. xiii.:

REG

The diameter of the sphere being 2, the circumference of the greatest circle is 6.28318
Superficies of the greatest circle 3.14159
Superficies of the sphere 12.56637
Solidity of the sphere 4.18859
Side of the tetrahedron 1.02909
Superficies of a tetrahedron 4.6188
Solidity of a tetrahedron 0.15132
Side of a cube or hexahedron 1.1547
Superficies of the hexahedron 8
Solidity of the hexahedron 1.5306
Side of an octahedron 1.4142
Superficies of the octahedron 6.9282
Solidity of the octahedron 1.33333
Side of the dodecahedron 2.73816
Superficies of the dodecahedron 10.31462
Solidity of the dodecahedron 2.85316
Side of the icosahedron 1.05146
Superficies of the icosahedron 9.95734
Solidity of the icosahedron 2.33613

If one of these five regular bodies was required to be cut out of the sphere of any other diameter, it will be, As the diameter of the sphere (2), is to the side of any one solid inscribed in the same (suppose the cube, 1, 1347), so is the diameter of any one sphere (suppose 8), to 9.2376, the side of the cube inscribed in this latter sphere.

Let d be (Plate Miscel. fig. 358.) be the diameter of any sphere, and de of it =a1b2=b3.
Erect the perpendiculars up, and draw the line, de, ef, fr, and fis, then will:
1. re be the side of the tetrahedron.
2. df be the side of the hexahedron.
3. de be the side of the octahedron.
4. Cut de in extreme and mean proportion in b, and ef will be the side of the dodecahedron.
5. Set the diameter dr up, perpendicularly at r; and from the centre c, to its top, draw the line ec, cutting the circle in g.
Let fall the perpendicular gh, then is br the side of the icosahedron.

REGULAR curves, such as proceed gradually in the same geometrical manner with regard to the curvatures. See CURVE.

REGULATOR, in chemistry, an imperfect metallic substance that falls to the bottom of the crucible in the melting of ores, or impure metallic substances. The regular is now understood to be the pure metal.

REGULUS, in astronomy, a star of the first magnitude in the constellation Leo; called also from its situation, cor leonis, or the lion's heart. See ASTRONOMY.

REINDEER. See cervus.

REJOINER, in law, is the defendant's answer to the plaintiff's replication or reply. Thus, in the court of chancery, the defendant puts in an answer to the plaintiff's bill, which is sometimes also called an exception; the plaintiff's answer to this is called a replication, and the defendant's answer to that a rejoinder.

REJOINING, in architecture, filling up the joints of the stones in buildings. This ought to be performed with the best mortar, as that of lime and cement; and sometimes with plaster, as in the joints of vaults.
RELATIVE TERMS, in logic, are words which imply a relation; such are master and servant, husband and wife, &c.

In grammatical terms are those which answer to some other word foregoing, called the antecedent; such are the relative pronouns, who, whom, and, &c.

RELIEF, in law, is an instrument in writing, by which estates, rights, titles, entries, actions, and other things, are extinguished and discharged; and sometimes transferred, abridged, or enlarged; and in general, it signifies one person's giving up or discharging the right or action he has, or claims to have, against another, or his lands, &c.

A release may be either in fact or in law; a release in fact is where it is expressly declared, by the very words, as the act and deed of the party; and a release in law is that which acquits by way of consequence, as when a false creditor takes the debtor to be his own

RELIANIA, a genus of the class and order Syngenesia Polyma superfus. The calyx is imbricate, scarious; corollas of the ray many; pappus membranaceous; receptacle, chaffy. There are 16 species, herbs of the Gour

RELIEF, in law, a certain sum of money which the tenant holding by knight's service, grand seigniery, or other tenure (for which homage, or legal service, is due), and being at full age, and without the aid of his ancestor, paid by his father at his entrance.

RELIEVE, in a military sense, is to send off those men that are upon duty, and to bring others to take their place; thus, to relieve the guard, the trenches, &c. is to bring fresh men upon duty, and to discharge those who were upon duty before.

RELIBV, and RELIEF, are terms applied to that mode of working in sculpture by which figures are made to project from the ground or body on which they are formed, and to which they may be attached. The same term is used, whether the figure is cut with the chisel, modelled in clay, or cut in metal or plaster.

There are three kinds of reliefs:

1. Alto-relievo, or high relief, when the figures are so prominent from the ground, that merely a small part of them remains attached to it.

2. Mezzo-relievo, or half-relief, when one half of the figures rise from the ground, in such a manner that the figure appears divided by it.

3. Baso-relievo, or bas-relief (low relief), when the work is raised but little from the ground, in small medals, and generally in fresco, and other ornamental parts of buildings.

These reliefs are the comprehensive term by which all works in relief are denominated indiscriminately. See SCULPTURE.

RELIEVE, or RELIEF, in painting, is the detached manner in which the figures seem, at a due distance, to stand out from the ground of the painting. See PAINTING.

RELIGION, Seditious words in derogation of the established religion are punishable as treason to a breach of the peace. 1 H. 17.

REMAINDER, in law, is an estate limited in lands, tenements, or rents, to be enjoyed after the expiration of another particular estate.

An estate in remainder is an estate limited to take effect and be enjoyed after another estate is determined. As if a man seized in fee simple grants lands to one for 20 years, and after the determination of the said term, then to another and his heirs for ever; here the former is tenant for years, remainder to the latter in fee. In the first place, an estate for years is created or carved out of the fee, and given to the former, and the residue and remainder is left to the latter. But there are estates in remainder which are in fact only one estate; the present term of years, and the remainder afterwards, when added together, being equal only to one estate in fee. 2 Black. c. 11.

The word remainder is no term of art, nor is it necessary to create a remainder. So that any words sufficient to show the intent of the party, will create a remainder; because such estates take their denomination of remainder, whether natural and manner and manner of their existence after they are limited, than from any previous quality inherent in the word. See Fcarne on Remainders.

There is this difference between a remainder and a reversion, in case of a reversion, the estate granted, after the limited time, reverts to the grantor or his heirs; but by a remainder it goes to some third person, or a stranger.

REMEMBRANCCS, antiently called either of the remembrance, certain offices in the exchequer, whereby three are distinguished by the names of the king's remembrancer, the lord treasurer's remembrancer, and the remembrancer of the first-fruits. The king's remembrancer enters in his office all recognizances taken before the barons, for any of the king's debts, for appearances, or observing of orders; he also takes all bonds for the king's debts, &c; and makes out processes thereon. He likewise issues process against the collectors of the customs, excise, and others, for their accounts; and informations upon penal statutes are entered and sued in his office, where all proceeding in matters upon his book, and in his hand, remain. His duty further is to make out the bills of compositions upon penal laws, to state the statements of debts; and into his office are delivered all kinds of indentures and other documents, which concern the surveying of any lands to the crown. He yearly, in crastino Annuarum, reads in open court the statute for election of sheriffs; and likewise openly reads in court, the oaths of all the officers, when they are admitted.

The lord treasurer's remembrancer is charged to make out process against all sheriffs, escheators, receivers, and bailiffs, for their accounts. He also makes out warrants of fictitious, and for debts due to the king, either in the pipe or with the auditors; and process for all such revenue as is due to the king, on account of his tenures. He takes the account of sheriffs; and also keeps a record book, in which are registered all debts of sheriffs or other accountants pay their proctors due at Easter and Michaelmas; and at the same time he makes a record, whereby the sheriffs or other accountants keep their prescribed days, and pay their accounts to that officer. He keeps account of this office all the accounts of customers, comptrollers, and accountants, in order to make entry thereof on record; also all extants and transfers are certified here, &c.

The remembrancer of the first-fruits takes all compositions and bonds for the payment of first-fruits and tenth; and makes out process against such as do not pay the same.

REMITTING, to send, or to remit a sum of money, bill, or the like, is to send the sum of money, &c.

REMITTER, in law, is where one that has a right to lands, but is out of possession, has afterwards the freehold cast upon him by some subsequent defective title, and enters in virtue of that title; in this case the law remits him to his antient and more certain right, and by an equitable fiction supposes him to have gained possession in consequence and by virtue thereof; and this, because he cannot possibly obtain judgment at law, to be restored to his prior right, since he is hims the tenant of the land. 3 Black. 190.

RENOMA, the sucking-fish. See Eels.

REMOVER, in law, is where a suit is removed or taken out of one court into another; and is the opposite of remanding a cause, or sending it back into the same court whence it was removed.

RENDER, in law, is used in levy a fine; which is either single, whereby nothing is granted or rendered back again by the cognizor to the cognizor; or double, which contains a grant or render back again of some real common, or other thing, out of the land itself to the cognizor.

RENDEZVOUS, or BRENDEVOYS, a place appointed to meet in, at a certain day and place.

RENEALMIA, in botany, a genus of the monogynia order, belonging to the monandria class of plants. The corolla is tubular; the nectarium oblong; the calyx monophyllous; the anthera sessile, opposite to the nectarium; the berry is fleshy. There is only one species, a native of Surinam.

RENT, is a certain profit issuing yearly, out of lands and tenement corporeal.

There are at common law three kinds of rents; rent in service, rent charge, and rent seek, or rack rent.

Rent service is where the tenant holds his land of his lord by fealty and certain rent; or by homage, fealty, and certain rent; or by other service and certain rent; and it is called a rent service, because it has some corporeal service incident to it, which is chiefly the service. Rent charge is so called because the land for payment of it is charged with a distress. Rent seek, or rack rent, is where the land is granted without any clause of distress for the same. 1 Tost. 141.

The time for payment of rent, and consequently for a demur, is such a convenient time before the setting of the last day, as will be sufficient to have the money counted; but if the tenant meets the lessor on the land at any time of the last day of payment, and tenders the rent, that is sufficient; but the money is to be paid indifferently on that day, and therefore a tender on that day is sufficient. See DISTRESS.

RENTERS, in the manufactories, the name for line-drawers. It consists in sewing two pieces of cloth edge to edge, without doubling them, so that the seam scarcely ap-
and hence it is denominated fine-drawing. The French word meaning the same thing, and is derived from the Latin retrahere, or re, in, and trahere, because the scene is drawn in or covered. It is said that in the East Indies, if a piece of fine muslin is torn, and the threads of the fine-drawers, it will be impossible to discover where the rent was. In this country the dexterity of the fine-drawers is not so great as that of those in the East; but it is still such as to enable them to defend the revenue, by sewing a head or slip of English cloth on a piece of Dutch, Spanish, or other foreign cloth; or a slip of foreign cloth on a piece of English, so far as to pass the whole as a piece, and by that means avoid the duties, penalties, &c. The trick was first discovered in France by M. Savary.

RESTERING, in tapestry, is the working new warp into a piece of damaged tapestry, whether eaten by the rats or otherwise destroyed, and on this warp to restore the ancient pattern or design. The warp is to be of woollen, not linen. Among the titles of the French tapestry-makers is included that of resterers.

REVERSE, inverted. See Heraldry.

REPARATION FACIENDA, a writ which lies in divers cases, one of which is, where three are tenants in common, or joint tenants, as in a mortgage, of a mill or horse which is fallen into decay, and the one being willing to repair it, the other two will not; in this case, the party willing shall have this writ against the other two. P. N. B. 172.

REPARATION. A tenant for life or years, may cut down timber trees to make reparations, although he is not compelled thereto; as where a house is ruinous at the time of the lease made, and the lessee sells it to fall, he is not bound to rebuild it, and yet if he sells timber for reparations he may justify the same. Co. Litt. 54.

REPEAT, in music, a character shewing that what was last played or sung must be repeated or gone over again.

REP E LMENTS, medicines supposed to have the power of bringing back into the mass of the blood such morbid humours as had been secreted from it. The term is now lost out of the materia medica.

REP E RCU SION, in mechanics. See Reflection.

REFLECTION. Reflection, in music, a frequent repetition of the same sound.

REPERTORY, a place in which things are orderly disposed, so as to be easily found when wanted. The indexes of books are repertories, shewing where the matters sought for are contained. Common-place books are also kinds of repertories.

REP E TEND, in arithmetic, denotes that part of an infinite decimal fraction, which is continually repeated. Thus 2, 131, 131, the figures 13 are the repetend. These repetends chiefly arise in the reduction of vulgar fractions to decimals, as \( \frac{1}{7} = 0.142857 \) 142857 0.142857, and so on, for ever. A single repetend is that in which only one figure repeats itself, as \( \frac{1}{7} \) is a single repetend. A compound repetend is that in which two or more figures are repeated, as \( \frac{1}{11} = 0.131313 \). To find the value of any repetend, or to reduce it to a vulgar fraction, "taken the given repeating figure or figures for a numerator: and for the denominator, take as many 9s as there are figures in the repetend: this is the fraction answering to 123123, &c., is \( \frac{13}{99} \).

REPETITION, in music, denotes a repetition of a term or figure, or an entire composition, or even a whole strain, part of a strain, or double strain, &c. The repetition is denoted by a character called a repeat, which is varied so as to express the various circumstances of a repeat. Repeat means a figure which gracefully and emphatically repeats either the same word, or the same sense in different words.

REPLEADER. Whenever a repleader is granted, the pleadings must begin de novo at that stage of them, whether it is the plea, replication, rejoinder, or whatever else, wherein there appears to have been the first default, or deviation from the regular course. When a repleader is awarded, it must be without costs. 3 Black. 395.

REPLETION. See Medicine.

REPLEVIN, is the writ called replication figure. If any goods distrained by another, for any cause, and putting in surety to the sheriff, that upon delivery of the thing distrained, he will prosecute the action against the distrainer. Co. Litt. 12.

That the avowant is in the nature of a plaintiff, appears, 1st. from his being called an actor, which is a term in the civil law, and signifies plaintiff; 2dly, from being entitled to have judgment de novo habilato; 3dly, and as plaintiff or defendant to have a return of the goods distrained, 4th.

That the avowant is in the nature of a plaintiff, appears, 1st. from his being called an actor, which is a term in the civil law, and signifies plaintiff; 2dly, from being entitled to have judgment de novo habilato; and 3dly, from this, that the plaintiff might plead in abatement of the avowry, and consequently such avowry must be in the nature of an action. Cartl. 112.

Replevins by writ, issue properly out of chancery, returnable into the courts of K. B. and C. B. at Westminster. In order to obtain a reprieve, the application must be made to the plaintiff, or any of his deputies, and security given that the party replying will pursue his action against the distrainer; for which purpose, by the ancient law, he is required to put in pledges to protect the county, and if the right is determined against him, he will return the distress again, for which purpose he is to find pledges to make return. These pledges are discretionary, and at the peril of the sheriff. 3 Black. 147.

After the goods are delivered back to the party replying, he is then bound to bring his action of reprieve against the distrainer, which may be prosecuted in the county court where the distress of which he was the party, or in any other court or in any other place, which court or place the distrainer may be. If the court or place to which the distress of which the plaintiff was the party shall not be suitable to the court in which the action is brought, the plaintiff to be tried, he may remove it to the superior courts of king's-bench or common- pleas, the plaintiff at pleasure, and the defendant upon reasonable cause.

If the sheriff is shown a stranger's goods, and he takes them, an action of trespass lies against him, for otherwise he could have no remedy; for being a stranger he cannot have the writ of proprietary procedans; and was he not intituled to this remedy, it would be in the power of the sheriff to strip a man's house of all his goods. 2 Rol. Abr. 352.

If it is determined for the plaintiff, namely, that the distress was wrongfully taken, he has already got his goods back into his own possession, and shall keep them, and moreover recover damages. But if the defendant prevents by the decretal or nonsuit of the plaintiff, this be his de novo habilato, hendo, by which the goods or chattels which were distrained and then reprieved, are removed into his custody, to be sold, or otherwise disposed of as if a privation had been made. If the distress was for damage feasant, the distrainer may keep the goods so returned, until tender shall be made of sufficient amends. Rol. Abr. 146.

On a return being had to the same, the party desiring to have the cattle or goods restored, must shew them to the sheriff, for otherwise the sheriff may not know them.

REPLICATION, in logic, the assuming one's meaning the same term twice in the same proposition.

REPLICATION, an exception or answer of the plaintiff in a suit to the defendant's plea; and is also that which the complainant replies to the defendant's answer in chancery. The replication is to contain certainly, and not to vary from the declaration, but must pursue and maintain the cause of the plaintiff's action; otherwise it will be a depreciation in pleading, and going to another matter. 1 Inst. 304.

REPORT, in law, is a public relation of cases judicially argued, debated, resolved, or adjudged, in any of the king's courts, with the causes and reasons of the same, as delivered by the judges. Also when the court of chancery, or any other court, refers the stating of a case, or the comparing of an account, to a master, or any other, it certifies thereon is called a report.

REPOSE, in painting, certain masses or large assemblages of light and shade, which being well conducted, prevent the confusion of objects and figures, by engaging and fixing the eye so that it cannot attend to the other parts of the painting for some time; and thus leading it to consider the several groups gradually proceeding from stage to stage.

R E P R E S E N T A T I O N. There is an heir by representation, where the father dies, in the life of the grandfather, leaving a son, who shall inherit the grandfather's estate before the father's brother, &c.

REPRIEVE, to suspend a prisoner from the execution and proceeding of the law at that time. Every judge who has power to order any execution, has power to reprieve.

REPRISALS. See LETTERS OF MARQUE.

REPRISE, or Reprieve, at sea, is a merchant-ship, which, after its being taken by a corsair, privateer, or other enemy, is retaken by the opposite party. If a vessel thus retaken has been 24 hours in the possession of the enemy, it is deemed a lawful prize; but if it is retaken within that time, it is to be restored to the party in lawful possession. If the vessel thus retaken has been 24 hours in the possession of the enemy, it is deemed a lawful prize; but if it is retaken within that time, it is to be restored to the party in lawful possession, and if it has been led into any port, it is to be restored to the proprietor.

REPRODUCTION, is usually understood to mean the restoration of a thing before existing, and since destroyed. It is very well known that trees and plants may be
REPRODUCTION.

This particular. If a piece of stick, or any other substance, is brought near them, they do not stay for its touching them, but begin to leap and frisk about as soon as it comes towards them. There want, however, some further experiments to ascertain whether this is really by the sense of sight, for though we can discover no distinct organs of sight in these creatures, yet they seem affected by the light of the sun or a candle, and always frisk about in some manner at the approach of either; and even the moonlight has some effect upon them.

A twig of willow, poplar, or many other trees, being planted in the earth, takes root, and becomes a most perfect piece of wood which will in the same manner produce other trees. The case is the same with these worms; they are cut to pieces, and these several pieces have perfect animals; and each of these may be again cut into a number of pieces, each of which will in the same manner produce an animal. It has been supposed by some that these worms were oviparous; but Mr. Bonett, by cutting one of them to pieces, having observed the fragment, resemblance a small filament, to move at the end of one of the pieces, separated it; and on examining it with his glasses, found it to be a perfect worm in some form with its parent, which lived and grew larger in a vessel of water into which he put it. These small bodies are easily divided, and very readily complete themselves again, a day usually serving for the production of a head to the part that wants one; and, in general, the smaller and more slender the worms are, the sooner they complete themselves after this operation. When the bodies of the large worms are examined by the microscope, it is very easy to see the appearance of the young worms alive, and moving about within them; but it requires great precision and exactness to be certain of this; since the ramifications of the great artery have very much the appearance of young worms, and they are kept in a sort of continual motion by the systole and dilatation of the several portions of the artery, which is the source of many hearts. It is very certain, that what we force in regard to these animals by our operations, is done also naturally every day in the brooks and ditches where the earthworms abound; the virtuoso observer will find in these places many of them without heads or tails, and some without either; as also other fragments of various kinds, all which are then in the act of completing themselves; but whether accidents have reduced them to this state, or they thus purposely throw off parts of their own body for the reproduction of more animals, it is not easy to determine. These are plainly liable to many accidents, by which they lose the several parts of their body, and must perish very early if they had not a power of reproducing what was lost; they often are broken into two pieces, by the residence of some hard piece of mud which they enter and they are subject to a disease, a kind of gangrene, rotting off the several parts of their bodies, and must inevitably perish by it, had they not this power.

This worm was a second instance, after the polype, of the surprising power in an animal of recovering its most essential parts when lost. But nature does not seem to have limited her beneficence in this respect to these two creatures. Mr. Bonett tried the same experiments on another species of water-crawls, discovered in being much thicker. This kind of worm, when divided in the summer season, very often shows the same property; for if it is cut into three or four pieces, the pieces will lie dead for a long time; but afterwards will move about again; and will be found in this state of rest to have recovered a head, or a tail, or both. After recovering their parts, they move very little; and according to this gentleman's experiments, seldom live more than a month.

It should seem, that the more difficult success of this last kind of worm, after cutting, and the long time it took to observe, that in the last parts, if it does recover them at all, are owing to its thickness; since we always find in that species of worms which succeeds best of all, that those which are thinnest recover their parts much sooner than the others.

The water-insects also are not the only creatures which have this power of recovering the lost parts. The earth abundes us some examples, which, when cut in such manner from their cuttings, are less deserving our admiration than those of the water: the common earth-worms are of this kind. Some of these worms have been divided into three or four pieces; and some of these pieces after having passed two or three months without any appearance of life or motion, have then been able to reproduce a head or tail, or both. The reproduction of a worm, after such a state of rest, is no long work; a few days do it; but it is otherwise with the head, that does not seem to perform its functions in the divided pieces till about seven months after the separation. If in all these operations, both on earth and water-worms, the hinder part suffers greatly more than the fore part in the cutting; for it always tends itself about a long time, as if actuated by strong convulsions; whereas the head usually crawls away without the appearance of any great uneasiness.

The reproduction of several parts of lobsters, crabs, &c. makes those great curiosities in natural history. That, in lieu of an organic part of an animal broken off, another shall rise perfectly like it, may seem inconsistent with the modern system of generation, where the animal is supposed to be wholly formed in the egg. Yet has the matter of fact been well attested by the fishermen, and even by several virtuosi who have taken the point into examination, particularly M. de Recamier and M. Perron, whose skill and exactness in things of this nature will hardly be questioned. The legs of lobsters, &c. consist each of five articulations: now, when any legs happen to break, by any accident, as in walking, &c. which frequently happens, the fracture is always found to be in a part near the fourth articulation, and what that loss is precisely reproduced some time afterwards; that is, a part of a leg shoots out, consisting of four articulations, the first of which has two claws as before, so that the loss is entirely repaired. The virtuoso's leg is cured by design at the fourth or fifth articulation, and is thus broken off always comes again; but it is not so if the fracture is made in the first, second, or third articulation. In those cases, the re-
production is very rare if things continue as they are. For, as is exceedingly surprising, it is that they do not; for, upon visiting the lobster mained in these barren and unhappy articulations, at the end of two or three days, all the other articulations are found broken off; and it is asserted they have performed the operation on themselves, to make the reproduction of a leg certain.

The part reproduced is not only perfect, like that retracted, but also, in a certain space of time, grows equal to it. Hence it is that we frequently see lobsters which have their two large legs unequal, and that in all proportions. This shows the smaller leg to be a new one.

A part thus reproduced being broken, there is a second reproduction. The summer, which is the only season of the year when the lobsters eat, is the most favourable time for the reproduction. It is then performed in four or five weeks; whereas it takes up eight or nine months in any other season. The small legs are sometimes reproduced, but more rarely of them than the great ones; the horns do the same. The experiment is most easily tried on the common crab.

REPTILES, in natural history, are a order of amphibia, the character of which is, that they breathe through the mouth; have feet, and flat naked ears, without auricles. There are five genera of reptiles, viz.

Toad
Draco
Lucerta
Rana
Siren.

REPUISION, in physics, that property in bodies, by which, if they are placed just beyond the sphere of each other's attraction of cohesion, they mutually fly from each other.

That there is a force which opposes the approach of bodies towards each other, and which tends to separate them farther from each other, is obvious from the slightest view of the phenomena of chemistry. Thus, when we represent the north pole of a magnet A to the south pole of another magnet B, suspended on a pivot, and at liberty to move, the magnet B recedes as the other approaches; and by following it with A, at a proper distance, it may be made to turn round on its pivot with considerable velocity. In this case there is evidently some force which opposes the approach of the north poles of A and B, and which causes the movable magnet to retire before the other. There is then a repulsion between the two magnets; a repulsion which increases with the power of the magnets; and this power has been made so great, by a proper combination of magnets, that all the force of a strong man is insufficient to make the two north poles touch each other. The same repulsion is equally obvious on electrical bodies; and indeed it is by means of it alone that the quantity of electricity is measured by philosophers. If two cork balls are suspended from a body with silk threads, so as to touch each other; we charge the body with electricity, the cork balls separate from each other, and stand at a distance proportional to the quantity of electricity with which the body is charged; the balls of course repel each other. See Electricity.

But it is not in electric and magnetic bodies only that repulsion is perceived. Newton has shown that it exists also between two glasses. He found that when a convex lens is put upon a flat glass, it remains at the distance of the 1/4 th part of an inch, and a very considerable pressure is required to diminish this distance; nor does any force which may be applied bring them into actual mathematical contact; a force may indeed be applied sufficient to break the glasses in pieces; but it may be demonstrated that it does not diminish their distance much beyond the 1/5 th part of an inch. There is, therefore, a force of repulsion which prevents the two glasses from touching each other.

That the particles of air repel each other is evident; for a considerable force is required to keep them, as near each other as we find them at the surface of the earth; and when this force is removed, they separate from each other, that is to say, the air expands. Nor is it known how far this expansion extends; it is artificially expanded to 3000 times its usual bulk, and is doubtless at great heights in the atmosphere its expansion is still much greater than that.

On the other hand, air may be forcibly condensed, so that it may be made to approach nearer each other; but a considerable force is required to produce this effect; and this force increases nearly as the density: if it is removed, the particles again separate, and the atmosphere assumes its former bulk.

What are the limits of this condensation is not known; but air has been forcibly compressed to 1000th part of its natural bulk. Thus we see that the air may be made to approach 16 times nearer each other. The elasticity of air, or the effort which it makes when compressed to resume its former bulk, is evidently the consequence of a repulsive force which its particles exert. All gaseous fluids possess the same repulsive force, and are indebted to it for their elasticity.

The particles of solid elastic bodies likewise repel each other; for they also, when forcibly compressed, resume their former size, and of course their particles repel each other. It has been demonstrated by philosophers, that all liquids are capable of a certain degree of compression, and that when the compressing force is removed they resume their former bulk; consequently the particles of these bodies also repel each other.

All bodies then possess a repulsive force, which exerts itself at sensible distances or at insensible distances; of course the repulsions may be divided into two classes.

The only sensible repulsions with which we are acquainted, take place at small distances. They may be reduced to two kinds, namely, electricity and magnetism.

It has been ascertained, that bodies possessed of the same kind of electricity repel each other; and likewise that the same magnetic poles of bodies repel each other; while, on the other hand, differently electrified bodies, and the different magnetic poles of magnetic bodies attract each other.

Repulsion increases, as far as has been ascertained, inversely as the square of the distance; consequently, at the point of contact it is infinite.

In sensible repulsion is most conspicuous in elastic fluids, as air and the gases; but it is exhibited also by elastic bodies in general. In these, if a judgment can be formed from the experiments on air, the repulsion increases nearly at the rate of 1/2.

Inensible repulsion may either be a force inherent in the particles of bodies, or it may belong exclusively to some particular body combined with these particles. The first of these hypotheses seems to have been adopted by Newton.

Other philosophers have supposed that repulsion is not a property inherent in all matter, but confined to a peculiar substance which has been generally considered as calcareous. According to this hypothesis, there are two kinds of matter, one whose particles attract, another whose particles repel. Let us call the first cohesive matter, and the other calcareous; and let us suppose also, what must be the case, that cohesive matter and calcareous matter attract each other with a certain force, in certain circumstances. This will explain the expansive power of calcareous, which combining with other particles of other matter, destroys the cohesion of those particles, and acts upon the body as a repulsive force; and this appears at least to explain the repulsion which exists in elastic, and, perhaps, other fluids.

Before we quit this subject, it will be worth while to shew, by an example, that the repulsion between the particles of calcareous matter acts as a present chemical force, and that it affords a key to explain several phenomena which at first sight appear nearly contradictory.

Why do bodies require different temperature in order to unite? and why does the presence of calcareous in many cases favour, or rather produce, union, while it prevents or destroys it in others?

Some substances, phosphorus for instance, combine with oxygen at the common temperature of the atmosphere; others, as carbon, combine with oxygen at a higher temperature. To what are these differences owing?

It is evident, that what diminishes the cohesion which exists between the particles of any body, must tend to facilitate their chemical union with the particles of other bodies. This is the reason that bodies combine more easily when heated by friction, than, or when they have been previously reduced to a fine powder. Now calcareous possesses the property of diminishing cohesion; and it is evident why some bodies require a high temperature to cause them to combine, is that at a low temperature the attraction of cohesion is in them superior to that of affinity; accordingly, it becomes necessary to weaken that attraction by calcareous till it becomes inferior to that of affinity.

The quantity of calcareous necessary for this purpose must vary according to the strength of the cohesion and of the affinity; it must be inversely as the affinity, and directly as the cohesion. When we see precisely the force of the cohesion between the particles of any body, and of the affinity between the particles of that body and with any other, we can easily reduce the temperature necessary to calculation.

That calcareous or temperature acts in this manner, cannot be doubted, if we consider that other methods of diminishing the attrac-
tion of cohesion may be substituted for it with success. A large lump of charcoal, for instance, will not unite with oxygen at so low a temperature as the same charcoal will do when re-covered to a very fine powder; and charcoal will combine with oxygen at a still lower temperature, if it is reduced to its integral particles, by precipitating it from alcohol, as Dr. Hutton has shewn by the alcohol through red-hot copper. And to shew that there is nothing in the nature of oxygen and carbon which renders a high temperature necessary for their union, if they are presented to each other in different circumstances, they combine at the common temperature of the atmosphere; for if nitric acid, at the temperature of 6°, is poured upon charcoal-powder, well dried in a clay oven, and which charcoal takes fire, owing to its combining with the oxygen of the acid. And in some other situations, carbon is so completely divided that it is capable of combining with the oxygen of the atmosphere, or, to be in the same thing, of catching fire at the common temperature: this seems to be the case with those p.rophori that are formed by distilling to dryness several of the neutral salts with a certain acid. The observations are sufficient to show, that carbonic is in many cases necessary in order to diminish the attraction of cohesion.

But there is a difficulty still remaining. Hence it is certain that in those instances in which the bodies combine with oxygen without the assistance of any foreign heat, the combination is once begun, though a quantity of carbonic is necessary to begin the combination of carbonic and oxygen, it is not necessary to be surrounded by a great quantity of carbonic during the whole time of their combining with oxygen? Alcohol, for instance, if once kindled, burns till it is quite consumed; and this is the case with oils also, provided they are furnished with a wick.

We err very much, were we to suppose that a high temperature is not as necessary to these substances during the whole of their combustion as at the commencement of it: for Mr. Monge found, in making the trial, that a candle would not burn after the temperature of the air around it was reduced below a certain point.

All substances which continue to burn after being once kindled are volatile, and they burn the easier in proportion to that volatility. The application of a certain quantity of carbonic to alcohol volatilizes part of it, that is, diminishes the attraction of its cohesion, so much that it combines with oxygen. The oxygen which enters into this combination gives out as much heat as volatilizes another portion of the alcohol, which combines with oxygen in its turn, more heat is given out; and thus the process goes on. Oils and tallow exhibit the same phenomena; only the amount of carbonic to alcohol volatilizes part of it, that is, diminishes the attraction of its cohesion, so much that it combines with oxygen. The oxygen which enters into this combination gives out as much heat as volatilizes another portion of the alcohol, which combines with oxygen in its turn, more heat is given out; and thus the process goes on. Oils and tallow exhibit the same phenomena; only the amount of carbonic to alcohol volatilizes part of it, that is, diminishes the attraction of its cohesion, so much that it combines with oxygen. The oxygen which enters into this combination gives out as much heat as volatilizes another portion of the alcohol, which combines with oxygen in its turn, more heat is given out; and thus the process goes on. Oils and tallow exhibit the same phenomena; only the amount of carbonic to alcohol volatilizes part of it, that is, diminishes the attraction of its cohesion, so much that it combines with oxygen. The oxygen which enters into this combination gives out as much heat as volatilizes another portion of the alcohol, which combines with oxygen in its turn, more heat is given out; and thus the process goes on. Oils and tallow exhibit the same phenomena; only the amount of carbonic to alcohol volatilizes part of it, that is, diminishes the attraction of its cohesion, so much that it combines with oxygen. The oxygen which enters into this combination gives out as much heat as volatilizes another portion of the alcohol, which combines with oxygen in its turn, more heat is given out; and thus the process goes on. Oils and tallow exhibit the same phenomena; only the amount of carbonic to alcohol volatilizes part of it, that is, diminishes the attraction of its cohesion, so much that it combines with oxygen. The oxygen which enters into this combination gives out as much heat as volatilizes another portion of the alcohol, which combines with oxygen in its turn, more heat is given out; and thus the process goes on. Oils and tallow exhibit the same phenomena; only the amount of carbonic to alcohol volatilizes part of it, that is, diminishes the attraction of its cohesion, so much that it combines with oxygen. The oxygen which enters into this combination gives out as much heat as volatilizes another portion of the alcohol, which combines with oxygen in its turn, more heat is given out; and thus the process goes on. Oils and tallow exhibit the same phenomena; only the amount of carbonic to alcohol volatilizes part of it, that is, diminishes the attraction of its cohesion, so much that it combines with oxygen. The oxygen which enters into this combination gives out as much heat as volatilizes another portion of the alcohol, which combines with oxygen in its turn, more heat is given out; and thus the process goes on. Oils and tallow exhibit the same phenomena; only the amount of carbonic to alcohol volatilizes part of it, that is, diminishes the attraction of its cohesion, so much that it combines with oxygen. The oxygen which enters into this combination gives out as much heat as volatilizes another portion of the alcohol, which combines with oxygen in its turn, more heat is given out; and thus the process goes on. Oils and tallow exhibit the same phenomena; only the amount of carbonic to alcohol volatilizes part of it, that is, diminishes the attraction of its cohesion, so much that it combines with oxygen. The oxygen which enters into this combination gives out as much heat as volatilizes another portion of the alcohol, which combines with oxygen in its turn, more heat is given out; and thus the process goes on. Oils and tallow exhibit the same phenomena; only the amount of carbonic to alcohol volatilizes part of it, that is, diminishes the attraction of its cohesion, so much that it combines with oxygen.

The affinity of hydrogen is greater for oxygen than for the other gases which either of these gases. The oxygen is the other gases, and there is an attraction of cohesion between the particles of the oxygen and hydrogen; the same attraction subsists between those of nitrogen and oxygen; the affinity of all these affinities (namely, the affinity between hydrogen and carbon, the affinity between oxygen and carbon, the cohesion of the particles of the hydrogen, and the cohesion of the particles of oxygen) is greater than the affinity between the hydrogen and oxygen; and therefore no decomposition can take place. Let the affinity between

\[\text{Oxygen and carbon} \quad 50\]
\[\text{Hydrogen and carbon} \quad 50\]
\[\text{Cohesion of oxygen for hydrogen} \quad 4\]
\[\text{Cohesion of hydrogen} \quad 2\]

Sum of quiescent affinities \quad 108

The affinity of oxygen and hydrogen 105

The quiescent affinities being greater than the dissoluble affinities, no decomposition can take place.

Let now a quantity of caloric be added to the oxygen and hydrogen gas, it has the property of expanding them, of course of diminishing their cohesion; while its affinity for them is so small, that it may be neglected. Let us suppose that it diminishes the cohesion of the oxygen 1, and of the hydrogen 1; then the combination will now be 3 and 1; and the quiescent affinities being 104, while the divalent are 105, decomposition would of course take place, and a quantity of caloric would thus be set at liberty to produce the same effects upon the neighbouring particles.

Thus, then, caloric acts only by diminishing cohesion; and the reason that it is required so much in gaseous substances, and in those combinations into which oxygen enters, is the strong affinity of oxygen and the other bases of the gases for caloric; for owing to the repulsion which exists between the molecules of that substance, an effect is produced by adding large doses of it, contrary to what happens in other cases. The more it is accumulated, the stronger is the repulsion between its particles, and therefore the more powerful is its tendency to fly off; and as this tendency is opposed by its affinity for the body and the cohesion of its particles, it must diminish both these attractions.

REPUTATION, or FAME. The security of reputation, or good name, from the arts of detraction and slander, is a right to which every man is entitled, by reason and natural justice; since, without this, it is impossible to have the perfect enjoyment of any other advantage or right. 1 Bl. 134.

Reputation is properly under the protection of the law, as all persons have an interest in their good name, and scandal and defamation are criminal, though defamatory words are not actionable, otherwise than as they are a damage to the estate of the person injured. Wood's inst. 37.

REQUESTS, Court of, an ancient court which flourished in the nineteenth year of Henry VII. See Court.
gument, in the court of common pleas, that the court of request was then no court of equity.

**RES**

RESCRIPT, an answer delivered by an emperor, or a pope, when consulted by particular persons on difficult questions or points of law, to serve as a decision thereof.

**RESCUE,** or **Rescous,** is the taking away and setting at liberty against law, any distressed or confined person, of any case, or things, from damage or harm; but the more general notion of rescue is, the forcibly freeing another from an arrest or some legal commitment; which being a high offence, subjects the offender not only to an action is the suit of, or common injured, but likewise to fine and imprisonment at the suit of the king. Co. Lit. 160.

It goods are distrained without cause, or contrary to law, the owner may make rescue; but if there are odious-imposed fines, or though taken without any cause, the owner may not break the pound and take them out, for then they are in custody of the law. 1 Black. Comm. 116.

**RESEARCH,** in medicine, is a kind of prelude or voluntary played on the organ, &c. wherein the performer seems to search or look out for the strains and touches of harmony, which are belied in the regular piece to be played afterwards.

**RESEDA,** dyer's-seed: yellow-seed, suite; or wild-seed, a genus of the order of trigna, in the dodecaenra class of plants; and in the nature of vegetable stains, it is a species of the order, miscellaneous. The calyx is monophyllous and pinnate; the petals laminated; the capsule unilocular, and opening at the mouth. There are 13 species of which the most remarkable is, wild-seed, the plant is cultivated and much used for dyeing silk and wool of a yellow colour. The great recommendation of the plant is, that it will grow with very little trouble, without dung, and on the very worst soils. For this reason it is commonly sown with, or immediately after, barley or oats, without any additional care except drawing a bush over it to narrow it in; the reaping of the corn does it little or no hurt, as it grows but little the first year; and the next summer it is pulled and dried like flax. Much care and nicety, however, is requisite, so as not to injure either the seed or stalk; or, which sometimes happens, damaging both, by letting it stand too long, or pulling it too green. To avoid these inconveniences, a better method of culture has been devised. This new method is, to plough and harrow the ground very fine, without dung, as equally as possible; and then sowing a gallon of seed, which is very small, upon an acre, some time in the month of August. In about two months, it will be high enough to hoe, which must be carefully done, and the plants left about six inches asunder. In March it is to be hoed again, and this labour is to be repeated a third time in May. About the close of June, when the flower is in full vigour, and the stalk is become of a greenish yellow, it should be pulled; a sufficient quantity of stems being left growing for seed till September.

**RESERVE,** body of, or corps de reserve, in military affairs, the third or last line of an army, drawn up for battle; so called because they are reserved to sustain the rest, as occasion requires; and not to engage, but in case of necessity.

**RESIDENCE,** is the continuance of a person or vicar on his benefice. By Statute 43dGeo. III. chap. 84, it is enacted that the statute 13th Eliz. c. 39, and its continuating statutes, are repealed; and that the penal- or forfeiture, under the 21st Hen. VIII. are repealed; and that every spiritual person possessed of any archdeaconry, or other dignity, benefice, curacy, or chapel, who shall, without exemption, or sufficient cause, be absent from his benefice, or place where he has other dignity or benefice, and less than six months of the annual value (deducting all out-goings, except curate's pay); when eight months, two-thirds; and when the whole year, three-fourths. The penalty to go to the informer; but the penalty for non-residence cannot be recovered, if the person has resided a whole year without absence before the action is brought.

Besides the exemptions contained in the above-mentioned acts, the following persons are exempt: clerk, or deputy clerk, of the king's chapel; chaplain of the house of commons; chaplain-general of the forces; brigade-chaplain on foreign service; chaplain of the garrisons, or of the corps of artillery, during the time of attending such offices; chaplain to any British factory, or in the household of any British subject resident abroad; chaplain of a royal, or in his absence, the surrogate, or official, in an ecclesiastical court; minor canon, vicar, choral, or other officer, in any cathedral or collegiate church; deans, subdeans, priests, or scholar, in the king's private chapels; chaplain of the military asylum, of the hospitals of Chelsea, Greenwich, St. Mary, &c. and Plymouth, while attending their duty; preacher or reader at the inns of court; the three future or at present vice-presidents; public tutors, or chaplain, or such other public officers, in the universities, or at Eton, or Winchester, or schoolmasters or usher in the same, or at Westminster; and persons entitled by the last of the above-mentioned statutes to the privilege of non-residence, till after forty years of age, shall not be entitled to it after thirty. The bishops may, if they think fit, grant licences for non-residence in certain cases, the fee for which shall not be more than ten shillings, independent of stamp-duty; and if the bishop requires to grant the licence, the party who thinks himself aggrieved may appeal to the archbishop, on giving security for paying the expenses of the appeal: the reasons for granting the licences shall be transmitted to the archbishop, for his examination and allowance; and although in the absence of any sec., the vicar-general may grant them, and they shall not be void on the death or removal of the grantor, unless revoked by his successor.

A person, although he may reside on the living, is liable to the penalties of non-residence, if he resides in any other house than that appointed for his residence, except by such licence from the diocese as has been stated, or while the tenant to whom the house of residence has been let continues in possession.

**RESIDUAL FIGURE,** in geometry, the figure remaining after subtracting a lesser from a greater.

**RESIDUAL ROOT,** in algebra, a root composed of two parts or members, connected together by the sign + . Thus a + y is a residual root, so called because its value is no more than the difference between its parts x and y.

**RESIGNATION,** in the canon law, the surrendering a benefice into the hands of the collator, or bishop.

**RESIGNEE,** in law, the person to whom a thing is resigned.

**RESIN,** in natural history, a viscid juice oozing either spontaneously, or by incision, from several trees, as the pine, fir, &c.

**RESINS.** It is at present the opinion of chemists, that resins stand in the same relation to the volatile oils that wax does to the fixed. Wax is considered as a fixed oil saturated with oxygen, whereas resins, as volatile oils saturated with the same principle.

The resins are very numerous; and in account of the various purposes to which they are applied, and the peculiarity of their properties, constitute one of the most important classes of natural substances. Till lately they have been very much overlooked by chemists, who satisfied themselves with gleaning doubtful information from artists and manufacturers, who, from the erroneous opinions concerning them have of course been admitted into every system of chemistry. The subject has lately engaged the attention of Mr. Hatchett, whose consummate skill and happy talent for observation peculiarly fitted him for the task.

Resins often exude spontaneously from trees; they often flow from artificial wounds; and not uncommonly are combined at first with volatile oil, from which they are separated by distillation. The reader can be at no loss to form a notion of what is meant by resin, when he is informed that common resin furnishes a very perfect example of a resin, and that it is from this substance that the whole genus derived their name: for resin is very frequently denominated resin.

Resins may be distinguished by the following properties:

- They are solid substances, naturally brittle; have a certain degree of transparency, and a colour most commonly inclining to yellow.
- Their taste is more or less acrid, and hot like that of volatile oils; but they have no smell unless they happen to contain some foreign body. They are all heavier than water.
- Their specific gravity varies from 1.0180 to 1.2829. They are all non-conductors of electricity; and when excited by friction, their electricity is negative.

When exposed to heat, they melt; and if the heat be increased, they take fire; and burn with a strong yellow flame, emitting at the same time a vast quantity of smoke.

They are all insoluble in water, whether cold or hot; but when they are melted along with water, or mixed with volatile oil and then distilled with water, they seem to unite
with a portion of that liquid; for they become opaque, and lose much of their brittleness. This at least is the case with common resin. They are all, with few exceptions, soluble in warm, doubly when boiled with heat. The solution is usually transparent, and when the alcohol is evaporated, the resin is obtained unaltered in its properties. When the solution is mixed with water, it becomes milky, and the resin falls in the state of white powder. They are soluble also in sulphuric ether. Many of them are soluble in several of the fixed oils, especially in the drying oils. The greater number are soluble in the volatile oils; at least in oil of turpentine, the one commonly employed.

Hitherto it has been affirmed by all chemists, both ancient and modern, that the alkaloids do not exert action on the resins. Fournier, for instance, in his last work, affirms this in the most positive manner; but the experiments of Mr. Hatchett have demonstrated this opinion to be completely erroneous. He reduced a quantity of common resin to powder, and gradually added it to a boiling lixivium of carbonat of potass; a perfect solution was obtained of a clear yellow colour, and this change continued permanent after long exposure to the air. The experiments succeeded equally well with carbonat of soda, and with solutions of pure potass or soda. Every other resin tried was dissolved as well as rosins, and the discovery led to very important consequences. The well-known fact, that the soap-makers in this country constantly mix resin with their soap; that it imparts its yellow colour, its odour, and its easy solution in water, to this addition, ought to have led chemists to suspect the solubility of resins in alkalies. No such consequence, however, was drawn from this notorious fact.

It has been supposed also that the acids are incapable of acting upon the resins. Fournier is equally positive with regard to this, and Gren speaks of it in such a manner, that every reader must conclude that he had tried the effect of nitric acid upon resins. Yet Mr. Hatchett has ascertained this opinion likewise to be erroneous, at least as far as nitric acid is concerned. He found that resins were subjected to the actions of nitric acid in alkalies in the state of a curdy precipitate; but when nitric acid is added in excess, the whole of the precipitate is resolved in a boiling heat. This remarkable fact, which did not hold when sulphuric or muriatic acids were used, led him to try whether the resins were soluble in nitric acid. He poured nitric acid, of the specific gravity 1.38, on powdered resin in a tubulated retort; and by repeated distillation formed a complete solution of a brownish yellow colour. The solution took place much sooner in an open man than in a solution close vessels. The solution contains permanent, though the liquid exposed to the air. It becomes turbid when water is added; but when the mixture is boiled, the whole is redissolved. When Mr. Hatchett collected the liquid thus thrown down by water filtration, he found that it still possessed the properties of resin. The resin is thrown down from nitric acid by potass, soda, and ammonia; but an excess of these alkalies redissolves the precipitate formed. This reasoning, extended to muriatic or orange colourd liquids. When Mr. Hatchett dissolved resin in boiling nitric acid, the solution was attended with a copious discharge of nitrous gas; and when the powdered resin was thrown into cold nitric acid, a considerable effervescence soon took place, and a porous mass was formed, commonly of a deep orange colour.

When resins are subjected to destructive distillation, we obtain, according to Gen. carbetuted hydrogen and carbonic acid gas, a very small portion of accludios water, and much empyreumatic oil. The charred is light and brilliant, and contains no alkali.

When volatile oils are exposed for some time to the action of the atmosphere, they acquire consistency, and assume the properties of resins. During this change they absorb a quantity of oxygen from the air. Westrum put 30 grains of oil of turpentine into 40 cubic inches of oxymercic acid gas. Heat was evolved; the oil gradually evaporated, and assumed the form of yellow resin. Mr. Proust observed, that when volatile oil is exposed to the air, it is partly converted into a resin, and partly into a crystallized acid; usually the benzoic or the caphoric. Hence we see that volatile oil is converted into two distinct substances. During this change oxygen is absorbed; and Fournier has observed that a portion of water is also formed. It is probable, from these facts, that resin is volatile oil deprived of a portion of its hydrogen, and combined with oxygen.

Hermstadt affirms, that to know whether any vegetable substance contains resin, we have only to pour some sulphuric ether upon it in powder, and expose the infusion to the light. If any resin is present, the ether will assume a brown colour.

Having now described the general properties of resins, it will be proper to take a more particular view of those of them which are of the most importance, that we may ascertain how far each possesses the general characters of resins, and by what peculiarities it is distinguished from the rest. The most distinguished of the resins are the following:

1. Rosin. This substance is obtained from different species of fir; as the pinus abies, sylvestris, larix, balsamifera. It is well known, that some of the exudation from the pinus sylvestris, or common Scotch fir, which hardens into tears. The same exudation appears in the pinus abies, or spruce fir. These tears constitute the substance called turpentine, or tar, and are employed when bark is stripped off these trees, a liquid juice flows out, which gradually hardens. This juice has obtained different names according to the plant from which it comes. The pinus sylvestris yields common turpentine; the larix, turbine venetica; the balsamia, balsam of Canada, &c. All these juices, which are commonly distinguished by the name of turpentine, are composed of the same ingredient, namely, oil of turpentine, and resin. When the turpentine is distilled, the oil comes over, and the resin remains behind. When the distillation is continued to dryness, the residue is kept by the name of common rosin, or colophonium; but when the water is mixed with it while yet fluid, and incorporated by violent agitation, the mass is called yellow resin. During winter the wounds made in the fir-trees become incrusted with a white brittle substance called barras or galipot, consisting of resin united to a small portion of oil. The yellow resin made by mixing and agitating this substance in water, is preferred for most purposes; because it is more ductile, owing probably to its still containing some oil. The properties of turpentine are those which have been detailed in the former part of this article. Its uses are numerous and well known.

2. Mastich. This resin is obtained from the Pistacia lentis, or Mastich tree, in the Levant, particularly in the island of Chios. When transverse incisions are made into this tree, a fluid exudes, which soon concretizes into yellowish semitransparent brittle grains. In this state it is sold under the name of mastich. It softens when kept in the mouth, but imparts very little taste. This has induced surgeons to employ it to fill up cavities, which it does tolerably well. When heated, it melts, and exudes a fragrant liquid. It contains a little volatile oil. It dissolves readily in fixed oils and in alcohol; but is too fusible and opaque for insertion as a varnish. It is found soluble in alkalies and nitric acid with the phenomena described in the former part of this article. Its specific gravity is 1.074.

3. Sandarach. This resin is obtained from the Semecarpus orientalis, or common reaper. It exudes spontaneously, and is usually in the state of small round tears of a brown colour, and semitransparent, not unlike mastich; but rather more transparent and brittle. Besides the resinous part, it contains alkalies of principle. Mr. Hatchett found the resin of juniper soluble in alkalies and nitric acid. Its specific gravity is 1.992.

4. Elemi. This resin is obtained from the Anisyris elemifera; a tree which grows in Canada and Spanish America. Incisions are made in the bark during dry weather, and the resinous juice which exudes is left to harden in the sun. It comes to this country in long roundish cakes wrapped in flag-leaves. It is of a pale yellow colour, semitransparent; at first softish, but it hardens by keeping. Its smell is at first strong and fragrant, but it gradually diminishes. When distilled, it yields a portion of volatile oil. The residuum is a pure resin. Its specific gravity is 1.018.

5. Tacamahac. This resin is obtained from the Fagura octandra, and likewise it is supposed from the populus balsamifera. It comes from America in large oblong masses wrap in flag-leaves. It is of a light-brown, very brittle, and easily melted when heated. Mr. Hatchett found it soluble in alkalies and nitric acid with the usual phenomena. Its specific gravity is 1.086.

6. Auric. This resin is obtained from the hymezae courbaril or lecust tree, which grows to the North of Brazil. This resembles copal very much in its appearance; but is readily soluble in alcohol, which copal is not; this readily distinguishes them. It is so very frequently employed in the making of varnishes. Its specific gravity, according to Birsön, is 1.028.

7. Ladanum, or lobadaum. This resin is obtained from the cystus creticus, a shrub which grows in Syria and the Grecian islands.

8. Opopulaenum, or balm of Gilced. This resin is obtained from the amyris Gi-
11. Guaiacum. This resin is obtained from the guaiacum officinale, a tree which is a native of the West Indies. The resin exudes spontaneously, and is driven out melted by heating one end of the wood in billets previously bored longitudinally; the melted resin runs out at the extremity farthest from the fire. The resin is of a green colour, has some transparency, and is brittle. Its fracture is vitreous. When heated, it melts. It has no smell, and scarcely any taste. Alcohol dissolves it; but water has no effect upon it. When thrown on burning coals, it diffuses a fragrant odour. When swallowed in powder, it causes a burning sensation in the throat.

12. Botany Bay resin. This resin is said to be the produce of the sarcos resinera; a tree which grows abundantly in New Holland, especially in Botany Bay. Specimens of it were brought to London about the year 1799, when it was tried as a medicine. Some account was given of it in governor Philip's Voyage, and in White's Journal of a Voyage to New South Wales; but it is to be noted that it is of no account as an article of commerce.

13. Copaiva, or balson of copaiva. This resin is obtained from the copaiva officinale; a tree which grows in South America, and some of the West Indian islands. The resin juvenile exudes in water, which is made in the trunk of the tree. The juice thus obtained is transparent, of a yellowish colour, an agreeable smell, a pungent taste, at first of the consistence of oil, but it gradually becomes thick and dark. It is a combination of volatile oil and resin; the oil is easily obtained by distillation with water. It is employed in medicine.

14. Viny. This resin is obtained from the viny tree, Fracture solens, and the viny of Brazil. The resin exudes spontaneously from the trunk of the singular tree which yields it, especially if the bark is wounded. It is but first fluid, but becomes gradually cold when dried in the sun. According to governor Philips, it is collected usually in the soil which surrounds the tree, having doublet run down spontaneously to pieces of it, and to the various sizes of a yellow colour unless when covered with a greenish-grey crust. It is firm, yet brittle; and when pounded, does not stick to the mortar nor cake. In the mouth it is easily reduced to powder without sticking to the teeth. It communicates merely a slight sweetish astrignent taste. When moderately heated, it melts; on hot coals it burns to a sour, emitting a white smoke which has a fragrant odour something like storax. When thrown into the fire, it increases the flame like pitch. It communicates to water the flavour of storax, but is insoluble in that liquid. When digested, the proportions of two-thirds dissolve: the remaining third consists of one part of extractive matter, soluble in water, and having an astrigent taste; and two parts of woody fibre and other impurities, perfect tasteless and water; the solution has a brown colour, and exhibits the appearance and the smell of a solution of benzoin. Water throws it down unaltered. When heated, it produces an empyreumatic oil, and charcoal; but it gives no traces of any acid, alkali, or salt, even when distilled with water.

Twelve parts were boiled in a solution of soda in water; the resin was dissolved; the remaining ten parts were floating on the solution, cohering together in clots. No crystals were obtained by evaporation part of the solution; and when sulphuric acid was dropped into the solution, resin separated unaltered. When mixed with twice its weight of nitric acid, the resin swells unaltered on the surface; but when heat is applied, the insoluble portion takes place. The digestion was continued till the effervescence stopped, and the resin swam on the surface of the liquid, collected together in clots. It was then separated by filtration. It had the bulk of 1/4 of the resin that treated had acquired a bitter taste, was not so easily melted as before, and alcohol was capable of dissolving only one-half of it. The solution was brown, tasted like bitter almonds; and when mixed with water, let fall a yellow resinous precipitate of a very bitter taste. The insoluble portion mixed with water, but formed a turbid liquid, which passed through the filter. The nitric acid solution separated from the resin by filtration, was transparent; its colour was yellow; its taste bitter; and it tinged substances dipped into it of a yellow colour. By evaporation it yielded oxalic acid, and produced a yellowish powder. This last substance was insoluble in water, and scarcely soluble in alcohol. Its taste was exquisitely bitter, like quassia. It mixed with the saliva, and resisted the skin and unchanged yellow. The resin deposited continued bitter and yellow, but yielded no precipitate with potash and nitrat of lime. The bitter substance, into which this resin was thus converted by nitric acid, was considered as one of the theories that it is capable of producing the same changes on all the resin: but this conjecture has been verified only with regard to colophonium, which he found to yield equally a yellow bitter substance.

The green resin which constitutes the colouring matter of the leaves of trees, and almost all vegetables, is insoluble in water, and soluble in alcohol. From the experiments of Provost, we learn, that when treated with oxymuriatic acid it assumes the colour of a withered leaf, and acquires the resinous properties in greater perfection.

15. Copal. This substance, which deserves particular attention from its importance as a varnish, and which at first sight seems to belong to a distinct class from the resin, is obtained from the rhiz copalimum, a tree which is a native of North America; but the best sort of copal is said to come from Spanish America. Copal is a beautiful transparent resinous-like substance, with a slight tinge of brown. When heated it melts like other resins; but it differs from them in not being soluble in alcohol, nor in oil of turpentine without peculiar medicinal properties: but it does dissolve in the fixed oils with the same ease as the other resins. It resembles gum annie exactly in appearance; but is easily distinguished by the solubility of this last in alcohol. The specific gravity of copal varies.

RESISTANCE, or resisting-force, in philosophy, denotes, in general, any power which acts in an opposite direction to another, so as to stop or diminish its effect.

There are various kinds of resistance arising from the various natures and properties of the resisting bodies, and governed by various laws; as, the resistance of solids, the resistance of fluids, the resistance of the air, &c.

Resistence of solids, in mechanics, is the force with which the quiescent parts of solid bodies oppose the motion of other parts contiguous to them. Of these there are two kinds: The first where the resisting and the resisted parts, i.e. the moving and quiescent bodies, are only contiguous, and do not cohere; constituting separate and distinct bodies or substances, as, the friction of what Leibnitz calls resistance of the surface, but which is more properly called friction; for the laws of which, see the article Friction.

The second case of resistance, is where the resisting and resisted parts are not only contiguous, but cohere, being parts of the same continuous body or mass. This resistance was first considered by Galileo, and may properly be called cohesion.

Theory of the resistance of the fibres of solid bodies. To conceive an idea of this resistance, or cohesion of the parts, suppose a cylindrical body suspended vertically by one end. Here all its parts, being heavy, tend downwards, and endeavour to separate the two contiguous planes or surfaces where the body is the weakest; but all the parts of them resist this separation by the force which they cohere, or are bound together. Here then are two opposite powers, viz. the weight of the cylinder, which tends to break it; and the force of cohesion of the parts, which resists this force.

If now the base of the cylinder is increased without increasing its length, it is evident...
Then \( I' \times x = \frac{c}{I} \times x \), the weight of the prism; and \( x = \frac{c}{I} \times x \) is its momentum; also, \( \frac{d}{y} = \) the momentum of the prism \( x \) and \( x \) is its added weight. In like manner \( \frac{d}{y} + \frac{d}{y} = \) the momentum of the prism \( x \) and \( x \) is its added weight, which that broke it; consequently \( \frac{d}{y} + \frac{d}{y} = \frac{d}{y} + \frac{d}{y} = \frac{d}{y} \), the length sought, that just breaks with the weight \( g \) at the distance \( x \). If this weight \( g \) is nothing, then \( x = \sqrt{\frac{d}{y}} + \frac{d}{y} \times x \) is the length of the prism that just breaks with its own weight.

If two prisms of the same matter, having their bases and lengths in the same proportion, are suspended horizontally; it is evident that the greater has more weight than the lesser, both of equal lengths, and of its base; but it has less momentum on account of its length, considered as a longer arm of a lever, and has only more resistance on account of its base; therefore it exceeds the lesser in momentum more than it does in its resistance, and consequently it breaks more easily.

Hence appears the reason why, in making small machines and models, people are apt to consider the resistance be much less than the strength of certain horizontal pieces, when they come to execute their designs in large, by observing the same proportions as in the small.

When the prism, fixed vertically, is just about to break, there is an equilibrium between its positive and relative weight; and consequently those two opposite powers are to each other reciprocally as the areas of the lever to which they are applied, that is, as half the diameter to half the axis of the prism. On the other hand, the resistance of a body is always equal to the greatest weight which it will just sustain in a vertical position, that is, to its absolute weight. Therefore, substituting the absolute weight for the resistance, it appears, that the absolute weight of a body, suspended horizontally, is to its relative weight, as the distance of its centre of gravity from the fixed point or axis of motion, is to the distance of the centre of gravity of its base from the same.

The discovery of this important truth, at least as an equivalent to, and to which this is reducible, we owe to Galileo. On this system of resistance of that author, Maritot made an ingenious remark, which gave birth to a new system. Galileo supposes that where the body breaks, all the fibres break at once; so that the body always resists with its whole absolute force, or the whole force that it can possibly exert at any instant, and never breaks till entirely bent. Hence those nearest the fulcrum of the lever, or lowest point of the fracture, are stretched less than those farther off, and consequently employ less part of their force, and break later.

This consideration only takes place in the horizontal situation of the body; in the vertical, the fibres of the base all break at once; so that the body will at once resist the whole weight of itself, and never exceed the united resistance of all its fibres; a greater weight is therefore required here than in the horizontal situation; that is, a greater weight is required to overcome their several resistances one after another. See 'Timber, strength of.'
of a ball of lead, descending in water, is equal to that which a heavy body acquires by falling through a space of 14 feet; or, 

$$\sqrt{\frac{g_\text{water}}{g_\text{air}}} = \sqrt{\frac{1/4}{1/4}} = 1$$

nearly, or 8 times the root of the same space.

Hence it appears, how soon small bodies come to their greatest or uniform velocity in descending in a fluid, as water, and how very small that velocity is; which explains the reason of the slow precipitation of mud, and small particles, in water; as also why, in precipitations, the larger and gross particles descend sooner, and the lowest.

Further, where \( N = n \), or the density of the fluid is equal to that of the body, then \( N = n \), so that the velocity and distance descended are each nothing, and the body will just float in any part of the fluid.

Moreover, when the body is lighter than the fluid, then \( N < n \), and \( N - n \) becomes a negative quantity, or the force and motion tend the contrary way, that is, the ball will ascend up to the top of the fluid by a motrice force, which is as if it were a body, the body ascending by the action of the fluid, is moved exactly by the same laws as a heavier body falling in the fluid. Wherever the body is placed, it is carried up with a force equal to the difference of the weight of a fluid of the same bulk as the body, from the weight of the body, that is, a body heavier than the ball continually acts equally upon the body; by which not only the action of gravity of the body is counteracted, so as that it is not to be considered in this case, but the body is also carried upwards by a motion equally accelerated, in the same manner as a body heavier than a fluid descends by its spheric gravity; but the equality of acceleration is destroyed in the same manner by the resistance, in the ascent of a body lighter than the fluid, as it is destroyed in the descent of a body that is heavier.

For the circumstances of the correspondent velocity, space, time, &c. of a body moving in a fluid in which it is projected with a given velocity, or descending by gravity, see Dr. Hutton's Select Exercises, prop. 29, 30, 31, and 32, page 221, &c.

Resistance of the Air, is the force with which the resistance of fluids, or the air, is retarded by the opposition of the air or atmosphere. See GUNSMITh, PROJECTILES, &c.

The air being a fluid, the general laws of the resistance of fluids obey the same rules except only to some variations and irregularities from the different degrees of density in the different stations or regions of the atmosphere. The resistance of the air is chiefly of use in military projectiles, in order to allow for the differences caused in their flight and range by it. Before the time of Mr. Robins, however, I thought that this resistance to the motion of such heavy bodies as iron balls and shells, was too incomparable to be regarded, for the rules and conclusions derived from the common parabolic theory, were sufficiently exact for the common practice of gunnery. But that gentleman showed, in his New Principles of Gunnery, that, so far from being incomparable, it is in reality enormously great, and by no means to be rejected without incurring the greatest errors; so much so, that the range, at the most, in the air, to the distance of two or three miles, would in a vacuum range twice as far.

The quantity of this resistance, in the case of different velocities, Mr. Robins discharged musket-balls, with various degrees of known velocity, against his ballistic pendulums, placed at several
RESISTANCE.

and gradual, continually from the smallest to the highest velocities; and that the increased real resistance no where rises higher than to about double of that which Newton's theory gives it.

The subject of the resistance of the air, as begun by Robins, has been prosecuted by Dr. Hutton, to a very great extent and variety, both with the whirling-machine, and with cannon-balls of all sizes, from 1 lb. to 6 lb. weight, as well as with figures of many other different shapes, both on the fore part and hind part of them, and with planes set at all varieties of angles of inclination to the path or motion of the same; from all which we obtain the real resistance to bodies, for all velocities, from 1 up to 2000 feet per second; together with the law of the resistance to the same body for all different velocities, and for different sizes with the same velocity, and also for all angles of inclination.

RESISTANCES OF DIFFERENT BODIES.

</table>

In this table are contained the resistances to several forms of bodies, when moved with several degrees of velocity, from three feet per second to 80 feet. The columns of the bodies are at the tops of the columns, as also which end went foremost through the air; the different velocities are in the first column, and the resistances on the same line, in their several columns are avoirdupois ounces and the decimal parts. So on the first line are contained the resistances when the bodies move with a velocity of three feet in a second, viz. in the second column, for the small hemisphere, of 42 inches diameter, its resistance 0.08 ounces when the flat side went foremost; in the third and fourth columns the resistances to a larger hemisphere, first with the flat side, and next the round side foremost; the diameter of this, as well as all the following figures, being 66 inches, and therefore the area of the great circle being 32 square inches, or 7/6 of a square foot; then in the fifth and sixth columns are the resistances to a cone, first its vertex, and then its base foremost; the altitude of the cone being 26 inches, as the same diameter of its base; in the seventh column the resistance to the end of the cylinder, and in the eighth, that against the whole globe or sphere. All the numbers show the real weights which are equal to the resistances; and at the bottom of the columns are placed proportional numbers, which shew the mean proportions of the resistances of all the figures to one another, with any velocity. Lastly, in the ninth column are placed the exponents of the power of the velocity which the resistances in the second and third columns bear to each other, viz. that of the tenth-foot velocity bears to each of the following ones, the medium of all of them being as the 2.04 power of the velocity, that is, very little above the square or second power of the velocity, so far as the velocities in this table extend.

From this table the following inferences are easily deduced:

1. That the resistance is nearly in the same proportion as the surfaces; a small increase only taking place in the greater surfaces, and for the greater velocities. Thus, by comparing together the numbers in the second and third columns, for the bases of the two hemispheres, the areas of which bases are in the proportion of 173 to 32, or 5 to 9 very nearly, it appears that the numbers in those two columns, expressing the resistances, are nearly as 1 to 2 or 5 to 10, as far as the velocity of 12 feet; but after that, the resistances on the greater surface increase gradually more and more above that proportion.

2. The resistance to the same surface with different velocities, is, in these slow motions, nearly as the square of the velocity; but gradually increases more and more above that proportion as the velocity increases.

This is manifest from all the columns; and the index of the power of the velocity is set down in the ninth column, for the resistances 3
in the eighth, the medium being 2.04; by which it appears that the resistance to the same body is, in these slow motions, as the 2.04 power of the velocity, or nearly as the square of it.

3. The round ends, and sharp ends, of solids, suffer less resistance than the flat or plane ends, of the same diameter; but the sharper end has not always the less resistance. Thus, the hinderer, and the flat ends of the hemisphere and cone, have more resistance, than the round or sharp ends of the same; but the round side of the hemisphere has less resistance than the sharper end of the cone.

4. The resistance on the base of the hemisphere, is to that on the round, or whole sphere, as 25 to 1, instead of 2 to 1, as the theory gives that relation. Also the experimented resistance, on each of these, is nearly 1/4 more than the quantity assigned by the theory.

5. The resistance on the base of the cone, is to that on the vertex, nearly as 2 1/2 to 1; and in the same ratio is radius to the sine of the angle of inclination of the side of the cone to its base. In the first case, therefore, the resistance is directly as the sine of the angle of incidence, the transverse section being the same.

6. When the hinder parts of bodies are of different figures, as far as resistance is concerned, though the fore-parts are exactly alike and equal; owing probably to the different pressures of the air on the hinder parts. Thus, the resistance to the fore-part of the cylinder, is less than on the equal flat surface of the cone, or of the hemisphere; because the hinder part of the cylinder is more pressed or pushed by the following air than those of the other two figures; also, for the same reason, the base of the hemisphere suffers less resistance than that of the cone, and the round side of the hemisphere less than the whole sphere.

Resistance of the fibres of solid bodies is more properly called cohesion.

Resolution in chemistry, &c. the reduction of a mixed body into its component parts, or first principles, by a proper analysis.

Resolution in music is when a consonant or interval figure is not written on a line, or in one part, but all the voices that are to follow the guide or first voice are written separately either in score, that is in separate lines, or in separate parts, with the pauses each to observe, and in the proper tone to each.

Respiration consists in drawing a certain quantity of air into the lungs, and throwing it out again alternately. Whenever this function is suspended, even for a very short time, the animal dies.

The fluid respired by animals is common atmospheric air; and it has been ascertained by experiment, that no other gaseous body with which we are acquainted, can be substituted for it. All the known gases have been tried; but they all prove fatal to the animal which is made to breathe them. Care has been taken that no air containing carbonic acid is concerned, may be divided into two classes: 1. Unrespirable gases; 2. Respirable gases. See Air.

1. The gases belonging to the first class are of such a nature that they cannot be drawn into the lungs of an animal at all; the episiotis closing spasmodically whenever they are applied to it. To this class belong carbonic acid, and probably all the other acid gases, as has been ascertained by the experiments of Pierre-Duphresne. Ammoniacal gas belongs to the same class; for the lungs of animals suffocated by it were found by Pluot not to give a green colour to vegetable blue.

II. The gases belonging to the second class may be drawn into the lungs, and thrown out again, without any opposition from the respiratory organs; of course the animal is capable of breathing them. They may be divided into four subordinate classes: 1. The first set of gases occasion death immediately, but produce no visible change in the blood. They occasion the animal's death merely by depriving him of air, in the same way as he would be suffocated by being kept under water. The only gases which belong to this class are hydrogen and azote. 2. The second set of gases occasion death immediately, but at the same time produce certain changes in the blood, and therefore kill, not merely by depriving the animal of air, but by certain specific properties. The gases belonging to this class are carburetted hydrogen, carbonic oxide, and perhaps also nitrous gas. 3. The third set of gases may be breathed for some time without destroying the animal; but death ensues if the animal is kept long enough to blow up the lungs. To this class belong the nitrous oxide and oxygen gas. 4. The fourth set may be breathed any length of time without injuring the animal. Air is the only gaseous body belonging to this class.

It has been long known that an animal can only breathe a certain quantity of air for a limited time; after which it becomes the most deadly poison, and produces suffocation in about a minute. This has been confirmed from his experiments, in order to prove the fact. Dr. Priestley and Mr. Scheele demonstrated, that the quantity of oxygen gas in atmospheric air is diminished; and Lavoisier demonstrated, in 1773, that oxygen gas, which did not previously exist in it, was found in air after it had been for some time respired. It was afterwards proved by Lavoisier, and many other philosophers, who confirmed and extended his facts, that no animal can live in air totally destitute of oxygen. Even fish, which do not sensibly respire, die very soon if the water in which they live is deprived of oxygen gas. Frogs, which can suspend their respiration at pleasure, die in about forty minutes, if the water in which they have been confined is covered over with oil. Insects and worms, as Vaccinia, which die, do so by the same means. These phenomena require air as well as other animals, and die like them if they are deprived of it. They diminish the quantity of oxygen in the air in which they live, and give it out, by respiration, the very same products as other animals. Worms, which are more retentive of life than most other animals, or at least not so much affected by poisonous gases, absorb every particle of the oxygen contained in the air in which they are...
The opinion that it is the oxygen only, and that the azote remains the same after respiration as before it. These conclusions were the consequence of the experiments of Lavoisier, who announced the non-alteration of the azote of the atmosphere in their earliest period of his researches. This conclusion seems to have been the consequence of the opinion which he entertained, that air is merely a mechanical mixture of the two gases, oxygen and azote. When he first adopted it, his apparatus was not delicate enough to measure small changes; and he does not appear to have afterwards examined the azotic residue with much attention. Mr. Davey has rendered it possible to Mr. Lavoisier of the azote of the air as well as oxygen disappears during respiration.

According to Dr. Menzie's, at every respiration 2.1885 cubic inches of oxygen gas are consumed. Now 2.1885 cubic inches of that gas amount to 0.6869 grains troy. Supposing, with Hales, that a man makes 1200 respirations in an hour, the quantity of oxygen gas consumed in an hour will amount to 0.8240 grains troy, and in 24 hours to 19776.672 grains, or 412104 ounces troy. This quantity exceeds that found by other chemists considerably; but the allowance of oxygen for every respiration is rather too great. Indeed, from the nature of Dr. Menzie's apparatus, it was scarcely possible to measure it accurately. According to the last experiments of Lavoisier and Seguin, a man, at an ordinary and convenient rate of respiration, 32.48437 ounces troy of oxygen gas: that is to say, that a quantity of oxygen gas, equal to that weight, disappears from the air which he respires in 24 hours. Indeed, the average quantity of air which disappears during every respiration is 1.4 cubic inch; of which 0.2 are azote and 1.2 oxygen. This, allowing 20 respirations per minute, as was the case with Mr. Davey (the subject of the experiment), amounts in 24 hours to rather more than 38 ounces of air; or precisely to 4.68 ounces of azote, and 33.54 of oxygen. This does not differ far from the other estimates obtained by Lavoisier, excepting in the azote, which the French chemist neglected altogether. We may consider it therefore as approximating to the truth as nearly as can be expected in the present state of the science.

2. That the air thrown out of the lungs contains carbonic acid, may be easily ascertained by blowing it through a tube into lime-water, which immediately becomes milky; and the bulk of the gas may be estimated by putting a portion of air from the lungs into a graduated jar standing over mercury, introducing a little baryatic water, or pure soda, to absorb the carbonic acid, and observing the diminution of bulk in consequence of this absorption. According to Lavoisier, a man in 24 hours throws out from his lungs at an average about 15.73 ounces troy of carbonic acid gas, as much as the experiments of Mr. Davey, on the other hand, it follows, that at every expiration about 1.1 cubic inch of carbonic acid is emitted, which amounts in 24 hours to no less than 37 ounces. The difference between these two sets of experiments is enormous, and claims a more complete experimental investigation to determine, whether the proportion of this gas emitted by different individuals, or by the same individual at different times, does not differ essentially. This supposition is surely very probable, as it tallies with what we know to be the case in other excrections; and it proves true, would the respiration continue, which has hitherto been ascertained. In the mean time, let farther experiments decide the point, we may consider Mr. Davey's conclusions as nearly the medium of the two, because they correspond with the earlier experiments of Lavoisier, and remove a very striking anomaly which appears when we compare Lavoisier's experiments on the respiration of man, with those produced in a laboratory. He took a guinea-pig into 708.090 grains troy of oxygen; and after the animal had breathed the gas for an hour, he took it out. He found that the oxygen gas now amounted only to 592.853 gr. Consequently there had disappeared 116.736 gr.

The carbonic acid gas formed was 130.472 gr.

The guinea-pig consumed in 24 hours 5.8308 oz. troy of oxygen gas, and emitted 6.9230 oz. of carbonic acid gas. Man, on the other hand, consumes in the same time 22.48437 oz. of carbonic acid gas. The oxygen gas consumed by the pig is to the carbonic acid gas emitted as 1.001:1.12; whereas in man it is 1.000:0.48; which would depend upon the accuracy of each of these experiments, they would prove, beyond a doubt, that the changes produced by the respiration of the pig are different, at least in degree, from those produced in man; but it is probable that some mistake has happened in one or other of the experiments.

3. It is not so easy to determine the proportion of water emitted from the lungs mixed with the air expired, as it is that of the carbonic acid. According to the experiments of Dr. Hales, it amounts in a day to 20.4 oz.; but his method was not susceptible of great accuracy. Mr. Lavoisier, on the other hand, estimated it at 28.55 ounces; but this proportion seems rather to have been the result of calculation than of any direct measurement. It can only be considered therefore as an approximation to the truth, and most probably a very imperfect one.

III. Let us now endeavour to ascertain the changes produced on the blood by respiration. The whole of the blood is propelled from the heart to the lungs, circulates through the vessels of that organ, and during that circulation it is exposed to the influence of the air with which it is constantly coming into contact. The slow changes are produced upon it by this action, which has been partly traced by the experiments of Priestley, Cigna, Fourcroy, Hussonfrat, Bedschode, Watt, and others, and all by the slow changes, as far as we are acquainted with them, are the following: 1. The blood absorbs air. 2. It acquires a florid red colour, and the chyle disappears. 3. It emits carbonic acid, and 4. It emits water, and perhaps hydrogen.

As the azote which has separated from the air during respiration is not to be found in the products of respiration, we must conclude that it has been absorbed by the blood. The experiments of Mr. Davey have rendered it exceedingly probable that the air is absorbed by the blood, and that it is afterwards decomposed by that liquid; and that the portion of azote which is useless is given out again, and mixed with the air in the lungs. The following facts render this opinion probable: first, the expired air is no, nor are any positive changes produced on the blood. When the gaseous oxide of azote is respired, it changes in quantity, and its composition; at the same time carbonic acid is evolved as usual, and a quantity of azotic gas makes its appearance. Now, as this azotic gas did not exist separately in the air before respiration, it must have been produced in conjunction with the separation of the oxide of azote; but its quantity being much less than the azote contained in the oxide of azote, which has disappeared, it follows that at least one fourth of azote has been absorbed by the blood unaltered; and if a part is thus absorbed, why not the whole? In that case the azotic gas must have been separated from the blood, in consequence of the decomposition of the oxide of azote absorbed. Now, as air is composed of precisely the same ingredients with the oxide of azote, as well as of the oxygen, of the air respired, it is impossible to suppose that the air is absorbed by the blood, and that the azotic gas which is developed is thrown out of the blood in consequence of the decomposition of the air absorbed. But farther, if the air is absorbed by the blood during respiration while the azote remains unaltered, oxygen gas ought to answer the same purposes as air. This gas, however, cannot be resired without occasioning death at last; and when it is respirated, the proportion of oxygen which disappears in a given time is much smaller than when the air is resired. Thus when 182 cubic parts of oxygen gas were breathed by Mr. Davy for but a minute, 11.4 cubic inches of the oxygen gas disappeared, whereas 15.6 cubic inches disappear in the same time when common air is resired. This is a demonstration of the useful in respiration, and not merely its oxygen; and if so, the air must be absorbed.

2. It has been long known that the blood which flows in the veins is of a dark-redish purple colour, whereas the blood in the arteries is of a florid scarlet colour. Lower observed that the colour of venous blood was converted into that of arterial during its passage through the lungs. No chyle can be distinguished by its white colour in the blood after it has passed through the lungs. The changes, then, which take place upon the appearance of the blood, are two: 1. It acquires a florid red colour; 2. the chyle disappears. Priestley himself knew that the change was produced by the air, and Mayow attempted to prove that it was by absorbing a part of the air. But it was not till Dr. Priestley discovered that air acquired a scarlet colour when put in contact with oxygen gas, and arterial blood a red colour when put in contact with hydrogen gas; or, which is the same thing, oxygen gas instantly gives blood the colour of arterial, and hydrogen on the
RESPIRATION.

573

contrary, gives arterial blood the colour of venous blood; it was not till then that philosophers began to attempt any thing like an explanation of the phenomena of respiration.

The blood is a fluid of very complex a nature, that it is not easy to ascertain the changes produced by the exposure to the atmosphere of the body, and even if that could be done, we have no method of proving that the effects of these gaseous bodies upon the coagulated blood are the same as would be on the blood in the motionless state, circulating in the vessels of a living animal. The facts which have been ascertained are the following:

1st. It appears from the experiments of Priestley, Girtanner, and Hassencrantz, that when venous blood is exposed to oxygen gas confined over it, the blood instantly assumes a scarlet colour, and the gas is diminished in bulk; therefore part of the gas has been absorbed. Mr. Davy indeed could not perceive any sensible diminution of the bulk of the gas.

2d. The same change of colour takes place when arterial blood is exposed to common air; and in that case the diminution of the bulk of the air is rather more sensible.

3d. Venous blood exposed to the action of azotic gas continues unaltered in colour; neither can any perceptible diminution of the gas ensue.

4th. Venous blood exposed to the action of nitrous gas becomes a deep purple, and about one-eighth of the gas is absorbed.

5th. The lungs along with the vessels, carbonic oxide becomes of a brighter purple, especially on the surface, and a considerable portion of the gas is absorbed.

6th. Venous blood exposed to carbonic acid gas becomes of a brownish-red colour, much darker than usual, and the gas is slightly diminished in bulk.

7th. Carburated hydrogen gas gives venous blood a fine red colour, a shade darker than oxygen gas does, as was first observed by Dr. Beddoes, and at the same time a small portion of the gas is absorbed. This gas has the property of preventing, or at least greatly retarding the combination of blood, as was first observed by Mr. Watt.

8th. When arterial blood is put in contact with azotic gas, or carbonic acid gas, it gradually assumes the dark colour of venous blood, as Dr. Priestley found. The same philosopher observed, that arterial blood acquired the colour of venous blood when placed in vacuo. Consequently this alteration of colour is owing to some change which takes place in the blood itself, independent of any external agent.

The arterial blood becomes much more rapidly and deeply dark-coloured when it is left in contact with hydrogen gas placed above it, what is the exact reason, therefore, the presence of this gas accelerates and increases the change, which would have taken place upon the blood without any external agent.

9th. If arterial blood is left in contact with oxygen gas, it gradually assumes the same dark colour which it would have acquired in vacuo, or in contact with hydrogen; and after this change oxygen can no longer restore its scarlet colour. It is therefore only upon a part of the blood that the oxygen acts; and after this part has undergone the change which occurs in the blood, the blood loses the power of being affected by oxygen.

10th. Mr. Hassencrantz poured into venous blood a quantity of oxymuriatic acid; the colour of the blood changed and assumed a deep and almost black colour. When he poured common muriatic acid into blood, the colour was not altered. Now oxymuriatic acid has the property of giving out its oxygen readily combined with the black colour was owing to the instant combination of a part of the blood with oxygen.

Such are the phenomena produced upon the blood by the different gases out of the body; but the science is not far enough advanced at present to be able to explain them in a satisfactory manner. The obvious changes produced on the blood in the lungs by respiration, are the florid red colour, and the disappearance of the dark red colour; a process which was explained as follows.

1. That carbonic acid is emitted from the lungs during expiration, has been fully ascertained; but whether it is formed in the lungs, according to the theory of Lavoisier, by the decomposition of the oxygen of the air with carbon emitted by the blood, or is emitted ready-formed from the blood at the same time that the air is absorbed, is not so obvious; but the latter opinion is more probable; and indeed follows from the supposition that air is absorbed without decomposition.

2. It is much more reasonable to conclude that the watery vapour which exalts from the lungs, has been diffused with oxygen, and carries it along with it through the blood-vessels. During the circulation the air is gradually decomposed by the blood, its oxygen, and part of its azote enter into combination, at the same time a portion of azote, of carbonic acid, and water, is evolved. When the blood returns to the lungs, it absorbs a new dose of air, and at the same time lets go the azote, carbonic acid, and watery vapour, which had been formed during the circulation. The same changes are again repeated, and the same substances emitted, every time the blood comes to the lungs.

It is probable that, during a considerable part of the day, there is a constant influx of chyle into the blood; and we are certain that lymph is constantly flowing into it. Now it appears, from the observations hitherto made, that neither chyle nor lymph contains fibrina, which forms a very conspicuous part of the blood. This fibrina is employed to supply the waste of the muscles, the work being from the body, and therefore, in all probability, requiring the most frequent supply. Nor can it be doubted that it is employed for other useful purposes. The quantity of fibrina in the blood, then, must be constantly diminishing, and therefore new fibrina must be constantly formed. But the only substances out of which it can be formed are the chyle and lymph, neither of which contains it. There must, therefore, be a continual decomposition of the chyle and lymph going on in the blood-vessels, and a continual new formation of fibrina. Other substances also may be formed; but it is certain that no fibrina can be formed, because it does not exist previously. Now, one great evil of respiration must undoubtedly be, to assist this decomposition of chyle, and complete formation of blood.

It follows, from the experiments of Fourcroy, that fibrina contains more azote, and less hydrogen and carbon, than any of the other ingredients of the blood, and consequently that of the chyle. In what manner the chyle, or a part of it, is converted into fibrina, it is impossible to say; we are not sufficiently acquainted with the subject to be able to explain the process. But we can see at least that carbon and hydrogen must be abstracted from that part of the chyle which is to be converted into fibrina; and we know, that these substances are actually thrown out by respiration. We may reasonably suppose, therefore, that the use of the air absorbed is to abstract a quantity of carbon and hydrogen from a part of the chyle by compound affinity, in such proportion that the remainder becomes insoluble; but the science of respiration is incomplete.

The complete formation of blood is not the only advantage gained by respiration; the temperature of all animals depends upon it. It has been long known, that those animals which breathe through the lungs, have a temperature much higher than the atmosphere; that of man is 98°. Birds, who breathe in proportion a still greater quantity of air than man, have a temperature equal to 103° or 104°. It has been proved, that the temperature of all animals is proportional to the quantity of air which they breathe in a given time.

These facts are sufficient to demonstrate, that the heat of animals depends upon respiration. But it is not to be doubted that Dr. Black's doctrine of latent heat became known to the world, that any explanation of the cause of the temperature of breathing animals was attempted. That illustrious philosopher, whose discoveries form the basis upon which all the scientific part of chemistry has been reared, saw at once the light which his doctrine of latent heat threw upon this part of physiography, and he applied it with so early to explain the temperature of animals.

According to him, part of the latent heat of the air inspired becomes sensible; and of course the temperature of the lungs, and the blood that passes through them, must be raised: and the blood, thus heated, communicates its heat to the whole body. This opinion was ingenious, but it was liable to an unanswerable objection; for if it was true, the temperature of the body ought to be greatest in the lungs, and to diminish gradually as the distance from the lungs in-
Crawford and Lavosiéer, who considered all the changes operated by respiration as taking place in the lungs, accounted for the origin of the heat almost perfectly; in the same manner with Dr. Black. According to them the oxygen gas of the air combines in the lungs with the hydrogen and carbon emitteed by the blood. During this combination the oxygen gives out a great quantity of caloric, with which it had been combined; and this caloric is not only sufficient to support the temperature of the body, but also to carry off the new-formed warmth, which thereby becomes exuded; and thus the temperature of the air inspired is raised. According to these philosophers, then, the whole of the caloric which supports the temperature of the body is evolved in the lungs. Their theory accordingly was liable to the same objection with Dr. Black's; but they obviated it in the following manner: Dr. Crawford found, that the specific caloric of arterial blood was 1.089; while that of venous blood was only 0.925. He hence concluded, that the instant venous blood is changed into arterial blood, its specific caloric increases; consequently it requires an additional quantity of caloric to keep its temperature as high as it had been while venous blood. This addition is so great, that the whole new caloric evolved is employed; the temperature of the lungs must necessarily remain the same as that of the rest of the body. During the circulation, arterial blood is gradually converted into venous; consequently its specific caloric diminishes, and must give out heat. This is the reason why the state of the veins, the extreme parts of the body do not diminish.

This explanation is certainly ingenious, but it is not quite satisfactory; for the difference in the specific caloric, granting it to be accurate, is too small to account for the great quantity of heat which must be evolved.

It is evident that it must fall to the ground altogether, provided, as we have reason to suppose, that the carbonic acid gas and water are not formed in the lungs, but during the circulation.

Since the air enters the blood, and combines with it in the state of gas, it is evident that it will only part at first with some of its caloric; and this portion is chiefly employed in carrying off the carbonic acid gas, the azotic gas, and the water. For the reason that the carbonic acid leaves the blood at the instant that the air enters it, seems to be this: The air combines with the blood, and part of its caloric units at the same instant, with the carbonic acid, and converts it into gas: another portion converts the water into vapour. The rest of the caloric is evolved during the circulation, when the oxygen of the air combines with hydrogen and carbon, and forms water and carbonic acid gas. The quantity of caloric evolved in the lungs seems not only sufficient to carry off the carbonic acid and water, which the diminution of the specific caloric must facilitate; but it seems also to raise the temperature of the blood a little higher than it was before. For Mr. John Hunter constantly found, that the heat of the heart in animals was a degree higher than any other part of the body, when it was examined. Now this could scarcely happen, unless the temperature of the blood was somewhat raised during respiration.

The heart has seen two uses which respiration seems to serve. The first is the completion of blood by the formation of fibrin; the second is the maintaining of the temperature of the body at a particular standard, notwithstanding which is continually giving out to the colder surrounding bodies. But there is a third purpose, which explains why the animal is killed so suddenly when respiration is stopped. The circulation of the blood is absolutely necessary for the continuance of life. Now the blood is circulated in a great measure by the alternate contractions of the heart. It is necessary that the heart should contract regularly, otherwise the blood would not go on: but the heart is stimulated to contract by the blood: and unless blood is made to undergo the change produced by respiration, it ceases almost instantaneously to stimulate. As the blood respiration is stopped, the heart ceases to be acted on, and therefore, is opposed to motion. See Motion.

Rest, in music, the same with pause.

RESTAURATION, in architecture, the art of repairing those parts of a building that are gone to decay, in such a manner as to give it its original strength and beauty. See Architecture.

RESTIO, a genus of the triandria order, in the diocese class of plants. The male calyx is an ovate scale of membranaceous scales; the corolla is proper, hexapetalous, and persistent. The female calyx and corolla are as in the male; the germen is roundish, and is sex-sucicled; there are three erect and persistent styles; the capsule is roundish, with six plats, and is rostrated and trilocular; seeds are angular and cylindrical. They are twenty-eight species, all natives of the Cape, some of them resembling rushes; and used for making brooms, thatching houses, &c.

RESTITUTION, of medals. See Medal.

RESTORATIVE. See Medicine, and Materia Medica.

RETAILER, in law, a servant who does not continually dwell in the house of his master, but only attends upon special occasions.

RETAINING FEES, the first fee given to a servant or counsel at law, in order to make him sure, and prevent his pleading on the contrary side.

RETARDATION, in physics, the act of diminishing the velocity of a moving body. See Resistance.

RETÉ MIRABILE, in anatomy, a small plexus, or net-work, of vessels in the brain, surrounding the pia mater. See Anatomy.

RETE MACULOSUM. See Cusps.

RETENTION, is defined, by Mr. Locke, to be a faculty of the mind, whereby it keeps or retains those simple ideas it has once received by sensation or reflection.

RETENTIO, also used as medicine, for the state of contraction in the solid or vascular parts of the body, which makes them hold fast their proper contents. In this sense retention is opposed to evacuation and conveyance.

RETICULA, or Reticule, in astronomy, a contrivance for the exact measuring the quantity of eclipses.

The reticule is a little frame, consisting of thirteen fine silken threads, equidistant from each other, and parallel, placed in the focus of object-glasses of telescopes; that is, in the place where the image of the luminaries is painted in its full extent; of consequence, when the sun or moon is seen divided into twelve equal parts or digits; so that to find the quantity of the eclipse, there is nothing to do but to number the luminous and the dark parts. As a square reticule is only proper for the diameter, not for the circumference, of the luminaries, it is sometimes made circular by drawing six concentric equidistant circles, which represents the phases of the eclipse perfectly.

RETINA, in anatomy, the expansion of the optic nerve on the internal surface of the eye, whereupon the images of objects being received, are impressed, and by that means conveyed to the common sensory in the brain, where the mind views and contemplates their ideas. See Optics.

RETO, or Retorite, in chemistry, a kind of hollow sphere of glass, used in brewing, and sometimes made circular by drawing six concentric equidistant circles, which represents the phases of the eclipse perfectly.

RETORT, in law, is where a plaintiff comes in person to the court where his action is brought, and declares he will not proceed in it, in which case the action is hanged or arrested. A retort differs from a non-suit in this, that it is always where the plaintiff or defendant is personally in court. See Nosuit.

RETRENCHMENT, in the act of war, any kind of work raised to cover a post, and fortify it against the enemy, such as fascines loaded with earth, gabions, barrels of earths, sandbags, and generally all things that can be thrown as a protection; and the general title. But retrenchment is more particularly applicable to a fosse bordered with a parapet; and a post fortified thus is called post retrenched, or strong post.

Retrenchments are either general or particular: general retrenchments are new fortifications made in a place besieged, to cover the besiegers when the enemy become masters of a lodgment on the fortification, that they may be in a condition of dispute the ground inch by inch, and putting a stop to the enemy's progress in expectation of relief.

RETROGRADATION, or Regression, the act or effect of a thing moving backwards.

The retrograde motion of the planets is an apparent motion, whereby they seem, to an observer upon earth, to move backwards, or contrary to the signs. See Astronomy.

RETURNS, return, or returns, in law, is used in divers senses: 1. Return of writ by sheriff and bailiff is a certificate, made by them to the court, of what they have done in relation to the execution of the writ di-
REVE, REVE, or GREVE, the bailiff of a franchise, or manor, thus called, especially in the west of England. Hence hire-reve, sheriff, port-greve, &c.

REVEL, a beat of drum about break of day, to give notice that it is time for the soldiers to arise, and that the sentries are to be on the alert.

REVELLS, entertainments of dancing, masked, acting comedies, farces, &c., and usually very frequent in the inns of court, and in noblemen's houses, but now disused. The officer who has the direction of the revels at court, is called the master of the revels.

REVENU, PUBLIC, the yearly income appropriated to the expenses of government. There are four different sources of public revenue: 1. The income derived from property vested in the public. 2. The emoluments of lucrative prerogatives annexed to the sovereignty. 3. Voluntary contributions from the people. 4. Taxes or imposts, not prodigiously and continuously exacted. From one or other of these great sources all public revenue must arise.

The revenue of the kings of England consisted formerly of various branches which were inherited from the crown. Of these, the rents and profits of the demesne lands of the crown might alone have furnished a very considerable income, as there are few estates in the country which have not been regarded as so much as the conquest been in the hands of the king. The custody of the lay revenues, lands, and tenements, of bishoprics during their vacancy, and of the temporalities of such abbeys as were of royal foundation, was made a productive source of revenue by some of the kings, who kept the sees a long time vacant to enjoy their income; Elizabeth kept the see of Ely vacant nineteen years for this purpose. First fruits and tenths of the livings of the clergy, were originally paid to the pope; but upon the destruction of his authority in England, were demanded by the crown as a legal and clerical supremacy. The other branches of the national revenue were, the profits of the military tenures; with the right of purveyance and pre-emption; and a claim to all property of which the king was surety, whether it be now in possession of others, such as treasure-trove or money-plate, or bullion found hidden in the earth; deadlands, and forfeitures of lands and goods for offences; walks, or goods stolen and thrown away by the thief in his flight; estrays, or valuable animals found wandering and the owner unknown; goods wrecked, if no proof could be made within a certain space of time who were the legal proprietors; the right to mines of silver and gold; and to certain fish, as whales and sturgeon, when either thrown on shore, or caught near the coast. These, with fines and forfeitures of various descriptions, not at one time, the ordinary revenue of the country, was made a productive source of revenue by some of the kings, who kept the sees a long time vacant to enjoy their income; Elizabeth kept the see of Ely vacant nineteen years for this purpose.

Sir John Sinclair, in his History of the Public Revenue, gives the following view of its amount at the commencement of each reign.

The taxation of the commonwealth was 20.000,000.
It.2741.2253.3418. in addition to the permanent and temporary taxes, constuting the public revenue. there are always certain incidental receipts applicable to the public service; such as the profits of lotteries, fees of the regulated exchequer-office, moneys repay'd by public accounts, &c.

REVERBERATION, in physics, the act of a body repelling or reflecting another after its impinging on it.

REVERSE of a medal, coin, &c. denotes the second or back side, in opposition to the head or principal figure. See MEDALS.

REVERSION, in heraldry, a thing turned backwards, or upside-down.

REVERSION, in law, is defined to be the re-turning of land, &c. to the possession of the donor, or his heirs. Reversion, in the law of England, has two significations; the one of which is an estate left, which continues during a particular estate in being; and the other is the return of the land, &c. after the particular estate is ended; and it is further said to be an interest in lands, when the possession of it falls; or where the estate which was for a time parted with, returns to the grantors, or their heirs. But, according to the usual definition of a reversion, it is the residue of an estate left in the grantor, after a particular estate granted away ceases, continuing in the grantor of such an estate.

The difference between a remainder and a reversion, consists in this: that the remainder may belong to any man except the grantor; whereas the reversion returns to him who conveyed the land, &c.

In order to render the doctrine of reversions easy, we shall give the following table; which shews the present value of one pound, to be received at the end of any number of years not exceeding forty, discounting at the rate of five, four, and three per cent. compound interest. See INTEREST.

</table>

The use of the preceding table.—To find the present value of any sum to be received at the end of a given number of years, discounting the sum of three, four, or five per cent. compound interest. Find by the above table the present value of one pound to be received at the end of the given term, which sum, by the number of pounds proposed (cutting off several figures from the product on account of the decimals), then the result will be the value sought. For example: the present value of 10,000/. to be received ten years hence, and the rate of interest five per cent. is equal to .6190 X 10,000 = 6190.00. Again, the present value of 10,000/. due in ten years, the rate of interest being three per cent. is 7.441 X 10,000 = 74411.

REVERSION of series, in algebra, a kind of reversed operation of an infinite series.

REVIEW, in chancery, is used for a bill where a cause has been heard, and a decree thereon signed; but some error in law appearing upon the decree, or new matter being discovered after it was made, this bill is given for a fresh examination into the merits of the case.

REVIEW, in war, is the appearance of an army, or part of an army, in order of battle, and their being viewed by the general, that he may know the condition of the troops.

REVIEW, is also the name of one kind of periodical publications, now too much prostituted (under the shelter of anonymous criticism) to the purposes of the malice of rival authors, and the petty artifice of interested booksellers.

REVISE, among printers, a second or third proof of a sheet to be printed; taken off in order to be compared with the last proof, to see whether all the mistakes marked in it are actually corrected.

REVIVOR, bill of, in chancery, is a bill for reviving a cause, where either of the parties dies after the bill and answer, and before the cause is heard; or if heard, before the decree is inviolate: in which case this bill must be brought, praying that the former proceeding may stand revived, and be put upon the same footing as at the time of the abatement.

REVOCATION, in law, signifies the recalling, or annulling, and making void, some power, grant, deed, &c. made before.

RHACHITIC. See Medicine.
Rhamnus, the buckthorn, a genus of the monogynia order, in the pantanida class of plants; and in the natural method ranking under the forty-third order, dimorne. The calyx is tubulous, with five minute scales along the rim of the stamina; there is no corolla; the fruit is a berry. There are forty-two species; of which the most remarkable are, 1. The catarticus, or common purging buckthorn, growing naturally in some parts of South America, it grows to the height of 12 or 14 feet, with many branches at the extremities. The leaves are oval-lanceolate, finely serrated on the edges, their nerves converging together. The flowers grow in clusters, not crooked foot-wide, and in this species divided into four segments; the fruit is a round black berry, containing four seeds. The juice of the berries is a strong purgative, and is made use of for making the common syrup of buckthorn kept in the shops. The bark is emetic; the juice of the unripe berries with alum dyes yellow; the rips ones a fine green; the bark dyes yellow. The green colour yielded by the berries, called in French the vert du ruisseau, is much esteemed by miniature-painters. Of this species there are two varieties, viz. the dwarf buckthorn, a shrub of about a yard high, columnar, but little show; and the long-leaved dwarf buckthorn, which is a larger shrub, with leaves somewhat larger, but in other respects very similar to the dwarf buckthorn. 2. The lotus has the trunk of the large-leaved or balsam-leaved, the zizyphus or judah; only with this difference: that the fruit is here round, smaller, and more lucious, and at the same time the branches, like those of the palmarum, are neither so stiff as the lotus, nor as the trunk of the Scriptures. This species is very common in the Jereedee and other parts of Bombay; and has been supposed by some to be the same species celebrated in the ancient poems, Homer for its enchanting property; though the latter is more generally supposed to have been a species of Diospyros. It is proper, however, to distinguish between both these shrubs, as a herb often mentioned by the ancients under the name of lotus. They are also different from the Egyptian lotus described by Herodotus; for which see Nymphaea. 3. The fragula, or berry-bearing alder, is a deciduous shrub, a native of England and most of the northern parts of Europe, and affords several varieties. 4. The alpine, rough-leaved fragula, or berry-bearing alder, is also a deciduous shrub, and native of the Alps. It differs in no respect from the common sort, except that it has no thorns, and that it will grow to be rather taller, with tough, large, and double laciniated leaves. The alpine fragula is a variety of this species, with smooth leaves and of a lower growth. 5. The paliurus, or thorn of Christ, a deciduous shrub or tree, a native of Palestine, Spain, Portugal, and Italy. It will grow to reach the height of 14 feet, and is armed with sharp thorns, two of which are situated at each joint, one is about half an inch long, straight, and upright; the other is scarcely half that length, and bent backward; and between them is the bud for the next years growth. This plant (says Houttyn) is undoubtedly the sort of which the crown of thorns for our blessed Saviour was composed. 6. The common alaternus is an evergreen tree, and native of the south of Europe. There are several varieties of this species; the most remarkable of which are the broad-leaved and the jagged-leaved alaternus, which have all been confounded with the phillyrea. 7. The insectivaler, or caperberry alaternus, is an evergreen shrub or tree, and native of Spain. It grows to the height of ten or twelve feet, and sends forth several branches from the base of the trunk. They are covered with a blackish or dark-coloured bark, and each of them is terminated by a long sharp thorn. The fruit continues on the trees all winter, making a beautiful appearance among the narrow clustered leaves at that season. 8. The oleoides, or olive-leaved buck horn, is an evergreen shrub, and native of Spain, and grows to the height of eight or ten feet. It sends forth numerous branches, each of which is the bed for a long sharp thorn. The flowers are small, of a whitish-green colour, and are succeeded by round black berries.

Rhapis, a genus of the monogynia order, in the pantanida class of plants; and under the fifth order, palmia. There are several varieties of this species; the most remarkable of which is the large-leaved and the jagged-leaved rhapis, of which there is a third variety, the palmia. The calyx is a monophyllous tritid spatha; the corolla monopetalous and tridual. There are two species, viz. 1. The large-leaved, or ground-natan, a native of China; 2. A rare variety, simple-leaved rhapis, a native of California.

Rhea Americana, the American ostrich, in size very little inferior to the common one; and is the bird for a long time illusory. This bird is flat on the top and rounded at the end; the eyes are black, and the lids furnished with hairs; the head is rounded, and covered with downy feathers; the neck is very long, and covered also; from the tip of one wing to that of the other extended, the length is eight feet; but from the want of continuity of the webs of these feathers, and their laxity of texture, the bird is not always able to incline from the ground; it is, however, capable of greatness, assisted itself by their motion in running, which it does very swiftly; the legs are stout, and bear feathers also; the hands, and furnished with three toes, all placed forwards, each having a straight and stout claw as in the casowary; on the heel is a callos knot, serving in place of a back toe; the general colour of the plumage is dull grey mixed with white, inclining to the latter on the under parts; the tail is very short, and not conspicuous, being entirely covered with long loose and floating feathers, having its origin from the lower part of the back and rump, and entirely covering it; the bill and legs are brown.

In respect to manners, it is said to be a very lordly bird; for instance, it flies, which it catches with great dexterity, and will also, like the common ostrich, swallow bits of iron and other trash offered to it. In common with the ostrich of the Old World, it lays its four eggs in the open air, in the same season, each of them holding a quart; but it differs from that bird in many particulars, especially in wanting the callousity of the sternum, and spurs on the wing. With these last the common ostrich is known to defend itself in defect of them, the bird here treated of trusts the feet with such boldness, as to become at once a furious and dangerous antagonist. The female calls its young ones together with a kind of whistling note somewhat similar to that of a man; when young it is very tame, frequently following the first creature it meets with. The flesh of this bird is said to be very unpalatable. It is found in various parts of South America, from Paraguay to Chili, and is known by the name of choique.

Rheidia, a genus of the monogynia order, in the pantanida class of plants; and in the natural method ranking with those of which the order is doubtful. The corolla is tetrapetalous; there is no calyx; and the fruit is a trispernum berry. There is one species, a tree.

HETORIC, in the most extensive sense of the word, denotes the art of composition, or that which enables us to apply language or speech to the best possible advantage. According to etymology, which often affords the most satisfactory explanation, the term signifies the art of pouring forth a stream of sentiment, and communicating with fluency our feelings and thoughts to others. It is derived from the Greek μέλος, to speak; and this again from μία, one, or μίχος, mixture. Another speech of the elocution of Nestor, says

Το και οι νυφινοι μεθοδοσίαν προσθήκατο. (Iliad. I. 49.)

"And out of his mouth flowed a harangue sweeter than honey."

Taken in this point of view, rhetoric will comprehend all polite literature, poetry perhaps excepted, the belles-lettres of the French, the pathetic and pleasant of every kind; compositions whose aim and end is not so much to inform or satisfy the understanding, as to move, incline, and persuade, by addressing the imagination, the affections, and, in some measure, sensation itself.

There cannot be a better rule for composing one more plain and practical, than what is laid down by Cicero, "to consider what is to be said; secondly, how; thirdly, in what words; and, lastly, how it is to be ornamented." We will venture to add, as a supplement even to Cicero, how far it ought to be ornamented.

The matter of any composition does not, properly speaking, fall under the cognizance of rhetoric; any farther than that there is an intimate connection between the subject and the style; and that the sentiments, whatever they are, naturally form, and raise or lower, swell or contract, the diction; on which we shall have occasion to make some observations when we speak of style.

But the second point in Cicero's rule, arrangement or order, is the most important, beyond all comparison, in every species of composition. It is laid down by Cicero, that the mind of the author is seen; the process of his thoughts; the connection of his ideas with one another, and with his main design.

In every composition it is required that there should be some plan or object; just as in every thing we do or say, there is some purpose or intention. All written compositions may be divided into discourse or reasoning, poetry, and history, including both

Vol. II.
narration and description. In all, unity of design is indispensable. In discourse or reasoning, the object is to prove and impress on the mind some truth or series of truths. Here the binding principle is causation; it explains the reason why such and such a thing must be so and so, and cannot be, or reasonably be supposed to be, otherwise. We believe certain things, it is true, on authority, or the testimony of others; but then it must be observed we judge of evidence by reason.

In respect to unity of design, there is a very near resemblance between epic poetry and history. The unity of design and action required in both differs not in kind but in degree. In epic or narrative poetry, the connection among the events related or described is more close and sensible. The narration is not carried on at a uniform rate for a long space of time; and the actors hasten to some remarkable period which satisfies the curiosity of the reader. This difference between the epic poem and history, depends on that particular situation of the imagination and the passions which is supposed in the former. The imagination of both writer and reader is more enlivened, and the passions more inflamed, than in history, civil, political, or literary, poetry. Any species of narration that confines itself to strict truth and reality. The same unity of design that runs through the epopeia, must also run through dramatic works, whether serious or tragic. Even in an ode, though the poet may be hurried from his plan for a time, or perhaps (as is sometimes the case, even with Horace) drop it altogether, there must appear some aim of design at least in the outset.

The connecting principle among the several events or circumstances which form the subject of a poem, may be very different according to the different designs of the poet. The design of a Poet is to produce some work that embraces every fabulous transformation produced by the power of the gods. Thus, his plan is formed upon the connecting principle of resemblance. The subject of poetry forms a distinct article in the present work; but as unity of design is a principle common to all kinds of composition, it saves repetition to glance at poetical as well as rhetorical or practical works, as far as this universal principle in all works of art is concerned.

As there may be different connecting principles in practical, so there may be in history and composition; and in every species of this composition, there must be some connecting principle, some bond of union among the different parts. Even in an epistle communicating or requiring information, there is a unity of design. In grave and serious letters, the subject is naturally and almost necessarily one; and even in the most light and familiar epistles there is this unity: that while they relate to a thousand particular inductions to all the world history, they all of them relate to the situation, circumstances, and feelings, either of the writer, or the friend to whom the letter is addressed. History, the design of which is both interesting and closely attended to, in the eye of the historian states-tered, even in proportion as the composition appears both uninteresting and detached to others. In memoirs and anecdotes too, we seek to know when and where certain materials for building an edifice, there is activity of design, in as much as they relate to some one person, or class of persons, some distinct time or period, or some place or country. Thus we have Memoirs of Frederick the Great of Prussia, Curious Collections relating to the State of Society in the Middle Ages, Court- and Empire of Russia. In biography, the unity of design is manifest. That there is an unity of design in natural history, consisting chiefly in classification as well as description, needs no illustration. But the grand province of history, and what is generally understood by the term, is

**History civil and political.** The state, progress, or vicissitude of society, in any particular period or country, in government, science, art, manners, and general civilization. The analyst, in his collections, or rather selections, (for it is not as absurd, nor as it is possible, to record of all things, guided by the connection of contingency in time or place, the philosophical, the true, and legitimate historian, by that of cause and effect. He traces the series of actions, accounted for by the order,复古至 their secret springs and principles, and delineates their most remote consequences. He chooses for his subject a certain portion of that great train of events which compose the history of mankind, in which link in this chain be endeavours to touch in his narration. Sometimes unavoidable ignorance renders all his attempts fruitless; sometimes he supplies at conjecture what is want of knowledge, and always he is sensible that the more broken the chain is, which he presents to his readers, the more perfect is his production. He sees that the knowledge of causes is not only the indispensable, (this relation or connection being the strongest of all); but also the most instructive: hence it is by this knowledge alone, that we are enabled to controvert events and govern the future." Hume’s Essay.

The matter of a composition being prepared, and the general design formed, the next thing to be considered is

**The order of arrangement of the parts of a composition.** And first of all, on this head, it may be observed that the authors of written compositions, usually, as is very natural and proper, set out with an introduction, whether in the form of a letter, or address to the reader, separate from the body of the work, or in the beginning of the work itself, without any distinction or separation. If the composition is addressed to the ear, the orator bespeaks the candid attention of his hearers by removing any prejudices they may be supposed to have conceived, and shewing the interest and importance of the subject of his discourse. He considers well what is the state or tone of mind of his hearers. To this he addresses himself in the first place; and endeavours to carry them along with him from one step to another, till through a train of reasoning he arrives at the conclusion. There is a familiar illustration of the nature and use of an introduction or exordium to be met with every day in our house of commons, where considerations often assure the house, when it begins to grow late, when or from any other cause, it betrays symptoms of impatience or inattention, that "they will not trespass on their time for more than a very few minutes;" the writer of a discourse or essay bespeaks the candid attention of his readers, by giving some general account of the nature of his design. It is a question in history or philosophy, that is, concerning either matter of fact, or relations of ideas, he follows up his introduction immediately with the history or the controversy. In some instances this statement and history are the only introduction; and, indeed, if the question is universally and highly interesting, there is no other introduction necessary: there can be none better. It is not only in doctrinal or didactic subjects that some introduction is required, but also in even in most poetical, especially the epic, and historical compositions. The poet announces and gives an outline of his subject and design at the outset of his work, in order to interest his reader in its farther development. He awakens curiosity by some of the most striking events in his narrative. Thus Homer tells you at once that he sings of the wrath of Achilles:

"That wrath which hurl'd to Pluto's dreary reign,
The souls of mighty chiefs, untimely slain."

Thus, in the Odyssey, he interests us in his design by a glimpse of the character of Ulysses, and his adventures after the redemption of Troy. Thus Virgil, having introduced us to the reader, by letting him know who he is, in the first book of the Aeneid gives a summary view of the hardships, sufferings, and designs of Aeneas. He introduces him first near the period when his designs were established; and so of the designs which could not fail to interest every Roman, and afterwards shews, as in perspective, the more distant events, circumstances, and causes, that led to their formation, and crowned them with success. Thus Milton interests the Christian reader by letting him know in the outset of Paradise Lost, that he sings

"Of man's first disobedience, and the fruit Of that forbidden tree whose mortal taste Brought death into the world, and all our woe, With loss of Eden, till one greater man Restore us, and regain the blissful seat."

Thus, also, Virgil announces his different designs in the exordium of his different books of Georgies; and thus also Thomson, in his Seasons.

In dramatic pieces there is no annunciation of a design, because suspension is kept up till the catastrophe. In tragedy, the design is, however, partly announced by the very name or names of the illustrious heroes or princes to whom it relates; and in comedy, the design is in some measure frequently expressed in the title; as In Love for Love; The Bussy-body; The Taming of the Shrew; The Careless Husband; the Jealous Wife; the School for Scandal. So there can be none better.

With regard to that most extensive and important branch of composition, civil and political history, here too an introduction or annunciation of the design is as natural as in the epopeia, and it may be added, it is precisely of the same kind. The general effect or impression, the most striking events, truth, inference, or moral, that remains uppermost in the mind, after reviewing any series of events, and which serves as a bond of union among the occurrences and transactions.
which the historian invades in the stream of his narrative, implies him, it is supposed, to communicate his views, sentiments, and emotions, to others. It is natural therefore, and as it is natural it is expected, that the historian, in most cases, should introduce his work by glancing at the importance and the nature of his main design or object. Thus Livy, in his much admired and truly admirable exercise of his design of inquiring into the cause by which the Roman empire was extended over the world, and reached to such a pitch of greatness that it seemed to tatter under its own weight. The design was noble and clear. There was no more distraction of it could not but draw attention. Thus Sallust chooses for a subject the Catilinarian conspiracy, because it was "in the highest degree memorable on account of the singularity, and the danger involved in the enormous crime." Thus also he writes an account of the Jugurthine war: "first, because it was great and terrible, and the success various; and secondly, because a check was then given, for the first time, to the pretensions of the nobility." In both cases he makes an apology for retiring from political life, and employing himself in the composition of history.

2. In didactic discourse, the speaker or writer, after an introduction, states the truth which he proposes to prove or illustrate, and also the chief propositions or points, by the establishment of which he forms his conclusion. This serves to keep up the attention of the hearer or reader to the main object, and the connection or dependance of this on the intermediate or subordinate propositions; but the heads must not be too many, for otherwise they would run into the embarrassment of multiplicity, and in fact cease to be heads.

3. As to the disposition of arguments, or order of placing them, it is proper, after proving your own position, to refute the arguments urged by gainsayers or adversaries.

Lastly, comes the conclusion of the discourse or treatise, or whatever it is called; which consists of two parts: a recapitulation of the principal arguments or circumstances, and an address to the passions.

In oratory too, it is observed by rhetoricians, besides the parts just mentioned, there is room for Digression, transition, and qualification. Where a subject is of itself but entertaining and dry, the orator is restored to the exertion of its powers by amusing digression; which, however, it is evident, should neither be too frequent nor too long, except, indeed, when the cause is very bad, and almost lost for this, in case, it is good economy to divert attention as much as possible from too nice a scrutiny into the subject.

Transitions are defined to be "forms in speech by which orators tell their hearers in a few words both what they have said already, and what they next design to say." When a discourse consists of a considerable number of parts, and especially when these are of considerable length, transitions are necessary; but sometimes, in passing from one thing to another, a very general hint is sufficient.

By amplification the orator enlarges and expatiates on a subject in such a manner as to represent it in the fullest and most comprehensive view, and as an enumeration of instances; he connects his position with a concurrence of various causes, and on the other hand, with a variety of effects; he places things in the light of consideration; he amplifies facts from the circumstances of time, place, and person in the like. To the order of historical composition, the general effect or impression of the whole of the materials, which serves as a bond of union among the events, and which historian weaves into his narrative, serves him also as a clue by which he winds back and unfolds the concatenation of circumstances which produced the grand event, or effect or effects, that first interested and induced him to transmit the whole to posterity. Every legitimate history, as well as epic poems, springs from some important truth or moral, as from its root; and shoots forth into various branches, twigs, leaves, and flowers, that, in the due time, it reproduces, in a manner, that fruitful which gave it birth; until by some issue or catastrophe, it impresses on the mind the doctrine, truth, or moral, which forms its principal object, and as the epic poet, after briefly announcing the subject that fires his soul, does not fly directly and rapidly to the end he has in view, but on the contrary, keeps long on the wing, and aims in his flight to warm the mind and to gratify its vast desires by frequent views of the grandeur, magnificence, and beauty of nature; so the historian diversifies and enriches his narrative with many incidents, circumstances, and episodes; various scenes are opened, various actors introduced, with various characters and manners.

As the historian is guided by his taste and judgment in the selection of his materials, so according to the measure of his taste and judgment he assigns them their place. To the order in which an infinite variety of materials may best be arranged under the eye that contemplates them, the rules or resources of rhetoric scarcely extend. If nothing more, yet certainly nothing better, can be said on the subject of order in general, than what has been said, in the two thousand years ago by Horace, and is still just

"Sit vicrum materiam, vestris qui scribitis, squam Viribus; et versate diu quid ferre recusat, Quid valeant humeri, cui lecta potuerit eres."

Nec facundia desert lacus, nec lucidus ordo.

De Arte Poetica, line 35—41.

"O ye writers! make choice of a subject suited to your powers; and ponder long on what your shoulders are able or not able to bear. Where there is a good choice, neither eloquence nor method will ever be wanting."

This is truth the question is, There is, however, as Horace immediately observes, room for taste or judgment, in the preferring of one order or arrangement of the particulars to another. The efficacy and grace of method consists in knowing when to say any thing, whether on the present, or whether, though pertinent enough to the present, it may not with advantage be reserved to some future occasion." The same just and accomplished critic says elsewhere, more generally.

Scribendi recte, supere principium et fimus.

De Arte Poetica, line 1289.

"The principle and spring of fine writing is good sense."

As good sense will prescribe just order in composition, so also it will suggest just and suitable sentiments.

Style: A style should correspond to the tone of mind of the author, and the tone and temper he wishes to communicate to others. The connection between the tone of mind and the diction is described by the same Roman poet, whose great master was Aristotle, in so just and connected a manner, that we shall content ourselves on the present point with quoting a small part of Horace, and referring our readers to the poet himself. Every subject need have a quintessence of itself. A comic subject does not admit of the pomp of a tragic strain; nor the bloody supple of Thyestes heard to be told in the simple numbers of comedy. Sometimes, however, comedy raises her voice, and Charies roused to anger and rage, gives vent to his sentiments in a high strain of indignation. Tragedians, on the contrary, lower their style to express their grief. It is natural for men to laugh with those that laugh, and weep with those that weep; the human countenance to vary with the sympathetic emotions of joy or sorrow. If you would have me shed tears, you must first shed them yourself. Plaintive words are most correspondent with a dejected look. Threats come well from a person in anger, mirth and pleasantry from a facetious temper, and grave remonstrances from a serious character." See De Arte Poetica, line 90—118.

Though these observations are made here with a reference to poetic, it is manifest that the spirit of them (namely, that language should be suited to the nature of the subject and is applicable to all composition; to common prose, to oratorical prose, to philosophical or didactic prose, and to historical prose; on each of which it is proposed to make a few observations.

But we premise a few remarks on the qualities that should prevail in style in general. They may be reduced to these: 1. purity; 2. elegance and dignity; 3. vigour; 4. harmony; 5. force and a beauty.

Purity consists in the choice of such words and phraseology as are agreeable to the most general and approved usage of the language in which we write. The offences against purity are accordingly divided into two, barbarisms and solecisms: the former respects single words, the latter their construction in sentences. The words and phrases that occur in writings, though in many re-
Spectators estimable, are not all of them pure, but only such as are agreeable to the usage of the approved writers; writers whose works descend from one generation and one age to another, without losing aught of their original interest and beauty. Thus, our English translation of Boccaccio, which is written in a popular style; so are the Spectators and other writings of Mr. Addison, and the letters and prefaces of Mr. Pope. "To purity of style it is necessary not only that it is formed according to the rules of philosophical or universal grammar, but according to the particular genius or idiom of the language in which we write. Thus, though "I see a voice" is allowable in Greek, and occurs in the twelfth verse of the Revelations, it would not be allowed in any original composition in English. Hence as it depends on the purity of a style whether a composition shall not become untranslatable and the away, or penetrate to posterity, and be transmitted to future ages, this, of all the qualities of style, may be considered as the most important. In the present day, in our country, there is a strong want of this, which consists not only of phrases degraded by common and trivial use, but of what may be called vulgar slang (if slang is not indeed an example itself of the abuse here noted), into the debates in pamphlets, and consequently no new or proper epistles, and a deluge of ephemeral histories. What reader of the next century will understand, "it is a hoax; meeting my idea; making up my mind; having the gift of thrift &c. &c. Even Mr. Hume, and other writers of note, especially among his countrymen the Scots, trespass greatly against purity, when they admit into their English style not only Scotchisms, but in many cases, are not generally on their guard, but so many Latin usages and Gallicisms. As to Latinity, this too has been used even immoderately by our great Dr. Johnson. Exegesis, like purity, consists partly in single words, and partly in their construction. As to single words, their force and propriety are to be judged of from the usage of the most generality of our times. The writer, at the period of our writing. For through length of time, words lose their original signification, and assume a new one, which then becomes their proper sense. Thus the word knave antiently signified a servant. In an old English version of the New Testament we find, "Paul, the knave of Jesus Christ." The proper and precise meaning of words, nearly synonymous, is to be distinguished with accuracy. For example; mercy and pity are sometimes confounded; though mercy is, properly speaking, exercised towards an offender, and pity towards one in distress. But though the meaning of all the words in a sentence, considered by themselves, may be very obvious, yet the sense of the whole may be obscured by a disorderly arrangement, of which a very apt and curious example is given by Quintilian. "A certain man, in his will left his heir should erect for him a statue holding a spear made of gold." A question here of great consequence to the heir arose; from the ambiguity of the expression; as it admitted of doubt whether the words, "made of gold," were to be applied to the statue, or to the spear. Care, therefore, must be taken to dispose both the words and parts of a sentence in such a manner as best agrees with their mutual connection and dependance on each other.

**Figure, or energy of style, depends chiefly on brevity and a judicious use of tropes and figures. Brevity consists in the use of general propositions and condensed terms, which are comprised, from a great number of particulars, the enumeration of which weakens a style, as in the material world bodies are weakened by dilatation. The use of figurative language, or tropes and figures, is of very great utility, and is a framework of dignity, and of beauty of style; but we embrace the first casion of making some remarks on its nature.

The ancient rhetoricians, who were fond of multiplying new comparisons, distinguished a trope from a figure; understanding by a trope a change in the usual meaning of words, and by a figure a change or division from the usual mode of constructing them in sentences, but they are generally confounded by the most accurate and purest writers. Both these kinds of changes, however, may be comprehended, even according to the rules of grammar, under the word trope, which occurs in the first book of Greek Ethics. As no language contains a sufficient number of proper words to express all the different conceptions of our minds, tropes were introduced to supply the deficiency; to express new ideas that could not occur naturally in our language. And these tropes contain a sufficient number of proper words to express all the different conceptions of our minds, tropes were introduced to supply the deficiency; to express new ideas that could not occur naturally in our language.

**Irony is a trope in which one thing is said, and the contrary intended. The subjects of irony are all manner of vices and follies, which are sometimes exposed in this way more pleasantly than by any other reason-ing. In irony, the author assumes the air of believing as others do; but by a development of the ground of belief, of the pro and the con, brings out the truth, and leaves the reader himself to draw the conclusion. We listen to the still voice of our own reason and conscience, and secretly condemn our own tenets or our own conduct, while pride and passion might raise a mist that might shade us from the light that should emanate from others. This figure of speech was used so much by Socrates, that he got the appellation of Eiron or Droll. The most perfect specimen of irony in the English language is Swift's Directions to Servants.

**Hyperbole, which exceeds the bounds of strict truth, and represents things as either greater or less than they really are, is the boldest of all tropes. The representation, however, is not made in such a manner as to impose on the hearer. It has always a very considerable effect, even when most extravagant; as it shows, at least, the opinion entertained by the speaker on any subject, in a very strong and striking manner. A hyperbole is a kind of embellishment. We meet with hyperboles even in the Scripture: "I hear you record," says St. Paul in his Epistle to the Galatians, chap. iv. "that if it had been possible ye would have plucked out your own eyes, and have given them to me," and the Evangelist John concludes his Gospel in these words. "There are also many things that Jesus did, which if they should be written every one, I suppose that even the world itself could not contain the books that should be written."

**Climax is a compound sentence in which the different parts or clauses are closely connected, and rise gradually in importance above one another. We have an admirable example of this trope in that passage of sacred writ, where it is said of the "joy of Heaven, that eye hath not seen, nor ear heard, neither hath it entered into the heart of man to conceive what things God hath prepared for them that love him."

**Metonymy is a trope which changes the names of things, either naturally though not essentially united, as the cause for the effect, or the effect for the cause; and. Thus, Mars put for war, Ceres for corn, and Bacchus for wine:

Impulant veteris Bacchi pinguesque farinae.
Virg.

Thus, in common discourse, it is usual to say, "this is such a person's hand, I know his hand," that is his writing.
Yet this was not burlesque; it was intended for a serious and heroic poem. In some instances it would appear as if writers were at pains to study the art of slinking. Mr. Lane Macgregor Buchanan meaning to do great honour, and to excel the isle of Skye, says, that "some of the vassals (of the great families there) are colonels, majors, captains, and lieutenants." Macgregor Buchanan's Defence of the Highlanders, page 86.

Dr. Swift observed the just order in composition when he made the tell the ladies who entertained him in a tavern:

"Had ye been coming stagers, Yourselves might have been treated by captains and by majors.

But it is not only in writers of the very lowest class that we find the antichrist. We have an example of this in Dr. Reid, where he says "the emotion raised by grand objects is awful, solemn, and serious." The order of these epithets should just have been inverted.

Inversion is a figure in speech in which the usual arrangement of words in a sentence, or in a sentence of a compound sentence or period, is inverted. For an example of the first kind, see Nisus in the Iliad, explaining:

"Me, me: adama quic feci; in me convertere ferrum."

"Me, me: here I am who have done the deed; on me turn your steel.

Under extreme agitation the usual process both of thought and speech is interrupted. The language of passion is bold and heretic. The impassioned mind rushes directly to the principal figure or object, from the action to the agent; from the attribute to the substance. Of the second kind, where the mind, though unruffled and composed, and thinking in a regular train, is animated to great conceptions, we have an instance in the first sentence of the Paradise Lost.

Antithesis is the illustration of one thing by another, and is, we presume, universally understood. If an explanation or illustration of it by an example is wanted, the reader is referred to the three last verses of the fourth chapter of St. Paul's Second Epistle to the Corinthians. There cannot be a happier example, and the reader is referred to it in every hand. Neither is it necessary to explain interregation or exclamation. The meaning of these figures is obvious from the very names given to them, and examples occur at every turn in all kinds of composition and discourse, written or spoken.

In an apostrophe, the speaker breaks off from the series of his discourse, and addresses himself to some particular person, present or absent, living or dead, or even to immaterial objects. A line example of apostrophe occurs in the second book of Paradise Lost, line 681-7:

"Whence, and what art thou, execrable shape?"

And a still finer in the fourth book, line 720—35: "Thus at their shady lodge arrived, both stood, Both turn'd, and under open sky ador'd The God that made both sky, and earth, and heaven,"

Which they behold; the moon's resplendent globe, And starry pole: 'Thou also mad'st the night, Maker omnipotent, and thou the day,' &c. See also the much admired apostrophe of Aeneas to his departed father Anchises: "Heu! genitori, omnis cura casisque levamen, Aemilius Anchises; hic me, pater, optime, fœsus Deseris, hest?" Aeneid, lib. iii. line 710.

"Here, alas! I lose my father Anchises, the soother of all my cares, my relief in every misfortune. Here, O thou best of parents! you me overcame with fatigue," &c.

Prosopopeia, or personification, either introduces an absent person as speaking, or one who is dead as if he were alive and present, and speech is attributed to some immaterial being. Ezr supposed that the prophet was writing of the celestial heaven, and could be eternally adored.

Inversion, and other similar figures, often break the usual order of thought, yet the effect is not as bad as it would seem. The sentence, "I found in the book of Job Job," on a review of his own actions, appears from the inaccessibility of men to the judgment of God. It could not be expected of a single poet that he should be possessed of the whirlwind and wind, &c., as in the Book of Job, chap. xxxvii—xlii.

There is not any figure better adapted to the purposes of the higher species of eloquence, that is, the pathetic and sublime, than the prosopopeia, by which the poet or orator may call all nature to his aid; but if it was introduced in any other than a highly impassioned strain, it would lose its effect, and even appear ridiculous. In all things the speaker is to consider well for what he has prepared the hearer.

Did our limits admit, most of our readers, and among these the most cultivated and intelligent, would excuse us from following the ancient rhetoricians, and those who tried in their footsteps, through all the tropes and figures to which the genius of true sublime language is given. A very ancient and highly admired instance of such a kind of nominal existence: sync Tempo, antonuma, litotes, euphemismus, catachresis, metaplexus, asyndeton, pleonasmus, poly- synvcton, antanaclasis, pioce, epizeuxis, &c.

On looking over this long catalogue of words, of so little practical use, we are almost inclined to say with Butler," For all a rhetorician's rules But teach him now to name his tools."

All tropes and figures rise naturally out of a well stored and brilliant imagination, an exuberance of thought, and the diffusive influence of the passions. The poet, the orator, animated himself, expands animation, life, and action to every object that comes in his way. To return now tovigour or energy of style.

How much this is promoted by figurative language will appear from this, that in proportion as the mind labours with any vivid emotion or conception, it is prone to give it a substantial form, to clothe it in metaphorical language. Now, a lively trope conveys not only a livelier, but often a juter idea of an object, than can be communicated by proper words in the most copious paraphrases. Thus, when Virgil calls the two copious two thunderbolts of war, he exhibits a more lively image of the rapid force and success of their arms, than could have been given in plain words. The next-mentioned great quality of style, was Harmony. As in music we require sound, uniformity, variety, and proportion, so we also require them, not only in compositions addressed to the ear, but in written compositions; for the reader considers of what he reads as if it was spoken by himself or by others. His ear, in some measure, runs over the page as well as his eye. Numbers are not confined to poetry; there is a rhythm, though of a more slow and sober kind, in prose. Here too we require sonorousness, uniformity, and variety of cadence. For these purposes there must be an intermixture of long and short words, and long and short sentences. As to the modulation of the voice in speaking, as well as of pronunciation, looks, and gesture, these belong to elocution, of which we have many professors. The sun of the style consists in the power to speak from feeling.—Si vis me here, &c.

The harmony of style is very much promoted by the use and invention of compound words, which any one is at liberty to contrive at pleasure, if he adorns what he supposes to be the language. As an example of all this, we produce a beautiful passage, which is a rural and domestic scene in Thomson's Seasons:

"In the pond The finely-chequered duck before her train Rows gaudily. The stately-sailing swan Give out his snowy plumage to the gale, And arching proud his neck, with oary feet Bears forward fierce, and guards his oiser-Isle Protective of his young. The turkey nigh, Loud-threatening reddens; while the peacock spreads His every-coloured glory to the sun, And swims in radiant majesty along."

Spring, line 773—32.

Nothing can be more harmonious.

Sublimity of style consists in language suitable to sublime emotions. Nay, the more plain and simple the images appear, the greater the surprise, wonder, and astonishment. It sometimes stands forth with rapidity and vehemence, and sometimes, like the tranquility of general views, exhibited in general terms.

As an instance of the power of simplicity in every species of composition that aims at the sublime and beautiful, we may contrast the style and manner of Michael Angelo and Zuccero in painting. Michael Angelo painted his figures naked; Federico Zuccero, who painted the cupola of Florence, peopled it with a multitude of both sexes, extremely well dressed in the fashion of the times. The style of Michael Angelo was sublime and beautiful; that of Zuccero little, and in process of time ridiculous.

Instances of the sublime are so abundant in poetry both sacred and profane, and in oratory, at least by that of the antients, that we leave the task of illustration on these two heads to our readers; but description and narration too, in prose, also admit of the sublime; and here it will be found to consist chiefly in the selection of the grandest objects and most striking circumstances, figurative language, brevity, and, above all, closely connected with brevity, the use of general
of the Active World, Feb. 1797. The metaphor being aptly kept up, gives beauty to the two first sentences here; the last rises into a style somewhat higher.

Having thus treated briefly of the principal qualities of style in general, we come now to a view of the proper character of the orator, as dependent on the different kinds of prose composition, which may be divided into four: the familiar or colloquial, the rhetorical, the philosophical, and the historical.

The "familiar or colloquial style, is that commonly adopted in polished conversation, of letters, meaning epistles, and of written dialogue, comical or serious. The style of conversation should be simple and plain: no elaborate sentences; no affectation of wit or eloquence; scarcely any great attention to grammatical accuracy: at least that attention should never be visible. To repeat what has been said ungrammatically, for the purpose of making oneself heard, is done by some persons, and it is most miserably pedantic. The greatest powers of conversation are shown in the turn and tone of conversation, in an ingenious and pleasing manner, leading it. It is easy to pour forth a show of knowledge, if one is allowed to lead the conversation; not so easy to illustrate any topic extemporaneous. The former shows only reading, the latter learning. There are a kind of babblers, familiarly called cockneys of the conversation, who, having furnished and loaded their memories at home, in set conversations or literary meetings, however denominated, say their lessons to an audience, and display an artificer and ingenuity, which is often imitated, and sometimes intelligently. This great metropolis abounds in illustrations of this position. In letters greater care and preparation is both allowable and required. Of epistolary writing we have some excellent models in the correspondences of Swift, Pope, Arbuthnot, Gay, and other wits of their time; but none, either in England or France, for ease, elegance, and energy of style, and the care observed with the utmost accuracy, to give their epistles of Cicero, Brutus, and other Romans of high rank and cultivated genius. As to written dialogue, the style of this seems to hold a middle ground between the familiar or colloquial, and the rhetorical, which may be divided into three kinds: the style proper for short and popular essays, that for a popular assembly, the senate of bar, and that for the pulpit. The subjects of the first-mentioned species of writing, are moral, critical, or entertaining; the thoughts must be condensed and close, and every thing to be said, said briefly, because the whole work itself is but short, and supposed to be read at some moment of leisure. The style should be plain and simple, that every one may understand it: yet so elegant that to one may be disagreeable who is not disposed to the present model of essays, in every respect, is Mr. Addison's papers in the Spectator, Guardian, and Freeholder.

The style of eloquence proper for a publication, admits of every possible variation or inflection, according to the tone and temper of the auditory, to what they can bear, or what they can listen to. One may be in a posture to sympathize with, rank, and in a humourous strain, or serious, solemn, rapid, impassioned, and vehement. This rule holds in some degree in speeches addressed to juries and to our house of commons. In the house of peers, the orators judge in civil cases, and that branch of the legislature which moderates and checks any effrontery that may appear in the resolutions of the more popular branch, the eloquence of the orator is to be, as it indeed is, more guarded, and better confined.

We have instances of the most pathetic and sublime eloquence among savage tribes. Witness the celebrated address of Logan, an Indian chief, to lord Dunmore, governor of Virginia. The great orators united the bold and unconfined tone of the rudest, with the knowledge and art of the most refined nations. The circumstances of climate, and form of government, in which they were placed, gave rise to the appeal in many, not in few laws, and the appeal in many, not in few instances of eloquence.

The eloquence of the pulpit is altogether of a serious, solemn, pathetic, and sublime cast. Here no rhetorical artifices are either admissible or necessary; the preacher must speak the truth, and nothing but the truth; and truth in such a manner as is increasing and important, so sublime and awful, that they are not to be heightened by any exaggerations of fancy. The language of scripture too, is infinitely more energetic and impressive than that of any human composition. The preacher has only to speak from believing, and to convince his audience that he really believes what he says, by the simplicity, truth, and profound knowledge of his subject and conduct. This is the charm that gave efficacy to the preaching of the bishops and Christian fathers, and success to the missionaries from Rome in modern times. Auditors in every discourse are incomparable, and this will arise out of the subject, treated in a rational and sensible manner. Never was any English divine more esteemed and admired, either as a preacher or a man, than Blackstone. He was an unguarded, disinterested, and unpretending man, who, as he sat in his congregation, while his action, and every look and gesture was adapted to the nature and variety of the subject and conduct.

Philosophical or didactic style. In pure philosophy illustrated by mathematics, nothing more is requisite or proper than purity and perspicuity. But moral philosophy, which is a combination of facts and principles, as natural philosophy is of facts and mathematics, admits of great eloquence, and should be made entertaining as possible.

Historical style. History may be divided into three heads. 1. Natural history. 2. Anecdotes of men. 3. History of voyages and travels. All of them contain, at least, materials for history. 3. Civil history, or the condition, actions, vicissitudes, and improvements of men united in society under different forms of government. To each of
RHEU

these there is a style in some measure appropriate, though in all the style should vary with the
variations of the subject. In natural
history, purity or propriety, and perspicuity of style is sufficient; nothing more is required.
But descriptions of natural appearances also
admit of elegance, and even sublimity, as
well as accuracy; of which Buffon furnishes
a pleasing example. It is a pity that so
clear a style, when well used, should be denied
the propriety of his countrymen to mere
theory. His obtrusion of theory, often whimsical and extravagant, is, indeed, so offensive
to a sober inquirer into the productions of
nature, that a strict and severe plausibility
is rather better pleased with the plainsness
of Pliny, and of Linnæus, whose views of both
plants and animals are at once so accurate and so considerable that you are enabled
to contemplate the sublime horrors of this
awful scene." Newt. Tour in England and
Scotland.

On viewing the scene, the reverend
Mr. Hall also raises his tone. "After seeing
the smoke ascending for more than a mile
as I advanced, and then saw the Clyde roaring and raging as if provoked at
resistance. The question started in my
mind, is nature then so basing and noisy in
her productions, or has the air or tone, the
character and passions of the observer, so
affected the fluid of contemplation, that you
contemplate the sublime horrors of this
awful scene." Newt. Tour in Scotland, by
an unusual Route, with a Trip to the Orkneys and Hebrides.

Civil history. This being addressed to
the whole world, to every country and every
generation, to philosophers, legislators, kings and
princes, the general style, air or tone, should be that of dignity; but it should not
be always elevated. It should vary with the
particular subject which is treated, which
may be done without descens into mean
measure.

The historian, Robertson, whose greatest
excellence, and a great excellence it is, con-
sists in the choice and beautiful order in which he deduces events from the causes that
gave them birth, i. e. shape, not sufficiently var-
rions in his style. He never condescends into
garden chor, or by the fireside; he never
descends from his pulpit.

It is to be observed, however, that some
designs admit of greater variety of style than
others. The Abbé St. Réal, who has given
so fine a specimen of the concise and rapid
style, in his History of the Conspicacy of
Venice, had not an opportunity, and could
not of propriety, or matter of his manner, so much as Mr. Hume in his
History of England, with occasional Sketches
of the principal States of Europe for seven hundred Years. Neither Thucydides nor
Sallust, confined by their designs to particu-
lar events and a very short period of time,
could expatiate at leisure on a variety of sub-
jects like Herodotus, who records the com-
ingenious acts of the Greeks and Barbari-
s for a long period of time; the scenes of
which narrative is extended over a consider-
able part of the three grand divisions of the
ancient world, and to a period of two cen-
turies. Thucydides writes the history of a
single war, and the scene of the events is con-
fined generally to the narrow spot of Greece.
The histories of Sallust are still more circumscribed in respect of both action and space.
The events of this great and strongly excited by the contemplation of one great
and approaching catastrophe, the dig-
ning concisness of Thucydides and Sallust,
for the greatest beauty. The arrangement
of Thucydides, his writing in the manner
of the event, and the approach of an event,
are defended in his style, as his subject and
his manner are admirable; yet it must be admitted that the style proper
for different plans or designs in history, admits
of modifications for different genius of
different historians. The retreat of the ten
thousand Greeks was a single event, and
embraced but a small portion of time; yet the
easy, graceful, and southern drawings of Néopomp, the Athenian hero, in an art
so admirable in its kind, though different from the
charming simplicity and melody of Her-
rodotus, the energy of Thucydides, the brevity
of Sallust, the dignity of T icy, and his happy
initiators among the moderns, Marenna and
Buchanan, and the elegant purity and pre-
cision of Julius Caesar. In a word, though
there are certain general qualities of style suited to a great and elevated subject, he is agree-
able熏tinctured, not deformed by a diversity
of genius.

Non una quidem
Nec diversa tamen quidallis decete esse sororum.

Now, to conclude, by recapitulating what
has been now said on the present article.
As speech is the power, so rhetoric is the art
of communicating our sentiments in the
fullest and most impressive manner. As the ends
for which we communicate our sentiments are
various, the form, style, or manner of dis-
course, spoken or written, is different also;
according to the emotions to be expressed
and excited, whether of surprise, com-
placey, admiration, wonder, astonishment,
virtue, ridicule, or scorn. The
first and cardinal point in every composition, is
the master of the subject; to have a clear con-
ception of all that we wish to say. " Out
of the mouth of the heart the mouth spoken." As
the analogies of language are formed before the rules of grammar, so literary works
were composed before the canons of criticism
and rules of rhetoric. These rules are of
more use in preventing the false glare of
turgidty, fustian, bombast, and conceit, than
of avail to inspire the most excellent qualities
of speaking or writing. An attention to these
rules will obviate banishes.

A well-considered, understanding, with a lively imagination and a feeling heart, are the grand sources of
excellent composition: a taste for which may
be further gained by reading the best of the models in the same manner that
the constant contemplation of the best pictures
forms insensibly a just and nice taste for painting; but should never be forgotten
that the highest excellences of skill are attained
where the fire of imagination is smothered by an anxious fear of offending against
any rules; and that the absence of faults and blemishes is dearly bought by the
absence of elegance and every beauty.

RHEUM, a thin serious humour, occasionally coming out of the glands about the
mouth or throat.

RHEUM, rubbhar, a genus of the mono-
gynous order, in the cucurbita class of plants,
and in the natural method ranking under the
12th order, holarrhæce. There is no calyx;
the corolla is sessile and persistent; and there
is one triangular stamen. There are seven
species. The most noted are:

1. The rhipidopodium, or common rubbhar,
as large, thick, fleshy, branching, deep-
striking root, yellow within; crowned by
ever large, rounded, heart-shaped, smooth
leaves, on thick, slightly-furred, foot-
shoots; and an upright strong stem, two
or three feet high, terminated by thick close
spikes of white flowers. It grows in trash
and Seythia, but has been long in the Eng-
lish gardens. Its root affords a gentle purge.
It is, however, of inferior quality to some of
the following sorts; but its young stalks in
spring being cut and peeled, are used for
pars.

2. The palamutum (see Picta Nat. Hist. fig.
346), a palument-leaved true Chinese rubbhar,
as thick fleshy root, yellow within;
crowned by very large, rounded, heart-shaped, smooth
leaves, on thick, slightly-furred, foot-
stalks; and an upright strong stem, five or six feet high or more, termi-
nated by large, soft white flowers. This
is now proved to be the true foreign rubbhar, of
the purgative quality of which is well known.

3. The campactus, or Tartarian rubbhar,
as large, fleshy, branched root, yellow within;
crowned with very large, heart-shaped, somewhat lobed, sharply indented, smooth
leaves, and an upright large stem, five or six feet high, branching above; having all
the branches terminated by nodding panicles of
white flowers. This has been supposed to be
the true rubbhar; which, however, of
superior quality to some sorts, is accounted
inferior to the thorn palamutum.

4. The undulate, undulated or wave-
leaved Chinese rubbhar, has a thick, branching,
deep-striking root, yellow within; crowned
with large, oblong, undulate, somewhat hairy
leaves, having equal foot-shoots, and an
upright strong stem, four or five feet high,
terminating by long loose spikes of white flowers.

5. The ribes, or current rubbhar of Mount
Lubusans, has a thick fleshy root, very broad
leaves, full of stipulated protuberances, and
with equal foot-shoots and branches; three
or four feet high, terminated by spikes
of flowers, succeeded by berry-like seeds,
being surrounded by a purple pulp. All
these plants are perennial in root, and the
leaves and stalks are annual. The roots being thick, sandy, generally divided, strike deep into the ground; of a brownish colour, without roots, the leaves rise in the spring, generally come up in a large head folded together, gradually expanding themselves, having thick, wool-stalks; and grow from one to two feet high, in height, and breadth, spreading till round; amidst them rise the flower-stems, attaining their full height in June, when they flower, and are succeeded by large triangular seeds, ripening in August. Some plants of each sort merit culture in gardens for variety; they will effect a simi-
larly with their luxuriant foliage, spicis, and flowers; and, as medical plants, they demand culture both for private and public use.

They are generally propagated by seeds sown in spring, or as soon as they are ripe, or early in the spring, in any open bed of light, deep earth. Scatter the seeds thinly, either by broad-cast all over the surface, and raked well in, or in shallow drills a foot and a half apart, and a half inch deep. The plants will rise in the spring, but not flower till the second or third year: when they are come up two or three inches high, thin them to eight or ten inches wide, and clear the ground through those designed always to stand will afterwards be hoed out to a foot and a half or two feet distance, observing if any are required for the pleasure-
ground, &c. for variety, they should be transplant ed, where they are to remain in autumn, when their leaves decay, or early in spring, before they shoot: the others re-
maining where some must have the ground kept clean between them; and in autumn, when the leaves and stalks decay, cut them down, and slightly dig the ground between the rows of plants, repeating the same work every year. The roots remaining, they increase naturally; and in the second or third year many of them will shoot up stalks, flower, and perfect seeds; and in three or four years the roots will be arrived to a large size, though older roots are generally prefer-
ed for both.
Rhinoceros, is found in various parts of Africa, and seems to have been the kind which was known to the ancient Romans, and by them cultivated in public gardens, and in combats of animals. In size it equals that of the common single-horned species; and its habits and manner of feeding are the same; but it differs greatly in the appearance of its skin, which, instead of the ordinary marked armour-like folds of the former, is merely a very slight wrinkle across the shoulders, and on the hinder parts with a few fainter wrinkles on the sides, so that, in comparison with the common rhinoceros, it appears almost smooth; the skin, however, is rough or tuberculated, especially in the larger species; but what constitutes the specific or principal distinction is, that the nose is furnished with two holes. In size it is smaller than the other, and situated above it, or higher up on the front. These horns are said to be loose when the animal is in a quiet state, but become firm and immovable when it is enraged. This observation is confirmed by Dr. Sparrman, who observed, in a specimen which he shot in Africa, that they were fixed to the nose by a strong appendix, or tendons, so as to allow the animal the power of elevating them at any time according to the fixture on proper occasions. This, indeed, is treated by Mr. Bruce, the celebrated Abyssinian traveller, as an absurd idea; but, on the contrary, I think, these additional horns, which are surrounded by the rains, trees of a softer consistence, and of a very succulent quality, which seem to be destined for his principal food. For the purpose of gaining the highest branches of these trees, his upper lip is so elastic, and of a bending property, as to be shot out so as to increase his power of laying hold with this in the same manner as the elephant does with his trunk. With this lip, and the additional horns, he can reach the upper branches which have most leaves, and these he devours first; having stripped the tree of its branches, he does not, therefore, abandon it; but, placing his snout as low in the trunk as he finds his horns will carry, he rolls up the body of the tree, and reduces it to thin pieces like so many laths; and when he has thus prepared it, he embraces as much of it as he can in his monstrous jaws, and twists it round with such exquisiteness as an ox would do a root of celery, or any such potato or garden-stuff.

When pursued, and in fear, he possesses an astonishing degree of swiftness, considering his size, the rapidity with which he runs, the great extent of his body, his great weight before, and the slenderness of his legs. He is long, and has a kind of trot, which, after a few minutes, increases in a great proportion, and makes him pass a surprising distance; but this is the way he is understood with a degree of moderation. It is not true, that in a plain he can beat the horses in swiftness. I have passed him with ease, and seen many savage mounted do the same, and, though it is certainly true that a horse can very seldom come up with him, this is owing to his cunning but not his swiftness.

The eyes of the rhinoceros are very small, and he seldom turns his head, and the horse sees nothing before him. To this he owes his death, and never escapes if there is so much plain as to enable the horse to get before him. His pride and fury, then, make him lay aside all thoughts of escaping, but by victory over his enemy. He stands for a moment at bay, then, at a start, runs straight forward at the horse like the wild boar, whom, in his manner of action, he is not so much resembles. The horse easily avoids him by turning short aside, and this is the fatal instant: the naked man, with the sword, drops from behind the principal horseman, and, unseated by the rhinoceros, who is seeking his enemy, the horse, he gives him a stroke across the tendon of the heel, which renders him incapable of further flight or resistance.

In speaking of the great quantity of food necessary to support this enormous mass, we shall consider the vast quantity of water which he needs. No country but that of the Shanghills, which he possesses, deluged with six month's rain, and full of large and deep basins, made in the living rock, and shaded by dark woody vegetation, or watered by long and deep rivers, which never fall low or to a state of dryness, can supply the vast drafts of this monstrous animal. But it is not that drinking alone that he frequents the marsh and marshy places: large, fleshy, and strong, as he is, he must submit to prepare himself against the weakest of all adversaries. The great consumption he constantly makes of water necessarily confines him to certain limited spaces; for it is not every place that can maintain him; he cannot emigrate, or seek his defence among the sands of Abarah.

The adversary just mentioned is a fly (probably of the genus.Runicus), which attacks the rhinoceros, as well as the camel and many other animals, and would, according to Mr. Bruce, as easily subdue him, but for the strategem which he practises of rolling himself up, or being made by night, into a ring, besides he clothes himself in a kind of case, which defends him from his adversary the following day. The pleasure that he receives from being in the midst of a cloud of dust, the darkness of the night, deprive of his usual vigilance and attention. The hunters steal secretly upon him, and lying on the ground wounding him with their javelins, mostly in the belly, where the wound is mortal.

RHINOMACER, a genus of insects of the order coleoptera. The generic character, antennae setisegous, seated on the snout; feelers four, growing thicker towards the end, the last joint truncate. There are three species: the curculio, that inhabits Italy: the attehnoides, that inhabits Sweden: and the ceratodes, found in Calabria.

RHIZOBALUS. A genus of the tereyzyz-morsen, in the polycandia class of plants, and in the natural method ranking under the 24th order, trinitia. The calyx is monozyzyzyzy, phylly, and downy; the corolla consists of five petals, which are round, conoical, phylly, and much larger than the calyx, white, conspicuous, filiform, and longer than the corolla: the stile are four, filiform, and of the length of the stamina; the pericarpum his four drugy, kidney-shaped, compressed, with a fleshy subcutaneous coat, mastic, but not a continuous, root inzg a kidney-shaped kernel.

Of this there are two species: the most remarkable is the peka. The nut is sold in the shops as American nuts: they are flat, tu- bulees, and kidney-shaped, having a kernel of the same shape, which is sweet and agreeable.

RHIZOPHORA, the mangrove or mangle, a genus of the monogyzy, order in the doceandia class of plants, and in the natural method ranking under the 12th order, holozal. The calyx is quadrangulate, the corolla four-petalled; there is one seed, very long, and carnous at the base. There are six species.

These plants are natives of the East and West Indies, and often grow 40 or 50 feet high. They grow only in water and on the bays of the sea. They advance a day. They preserve the verdure of their leaves throughout the year. From the lowest branches issue long roots, which hang down to the water, and penetrate into it, so as to constitute this position almost a kind of natural and transparent terrace, raised with such solidity over the water, that one might walk upon them, was it not that the branches are too much incumbered with leaves. The most common method, however, is that of laying the small lower branches in baskets of mould or earth till they have taken root.

The description just given pertains chiefly to a particular species of mangrove, R. magnolia, denoted by the West Indians black mangroves, on account of the brown dusky colour of the wood. The bark is very brown, smooth, and generally used in the West Indies for tanning of leather. Insence bark has leaves, and those of the same size, but is lighter, thinner, and more tender. The wood is nearly of the same colour as the bark: hard, plant, and very heavy. It is frequently used for fuel; the fires which are made of this wood being both clearer, more ardent and durable, than those made of any other materials whatever. The wood is almost incorruptible, never splinters, is easily worked, and is not, for its enormous weight, would be commodiously employed in almost all kinds of work, as it possesses every property of good timber. To the roots and branches of mangroves that are immersed in the water, and frequently attach themselves, so that wherever this curious plant is found growing on the sea-shore, oyster-fishing is very easy; as in such cases these shell-fish may be literally said to be set.
from all parts of the trunk. The bark is slender, of a brown colour, and, when young, is smooth, and adheres very closely to the wood; it when old, splits or cracks, and is easily detached from it. Under this bark is a skin as thick as parchment, red, and adhering closely to the wood, from which it cannot be detached till the tree is Killed and dried. The wood, when split open, is heavy, of a deep red, with a very fine grain. The pit or heart of the wood being cut into small pieces, and boiled in water, imparts a very pleasant and tincture very light and brittle. This species is generally called upon grove, from the use to which the bark is applied by the inhabitants of the West Indies. This bark, which, from the great abundance of surface is easily detached when green from the wood, is beaten or bruised between two stones, until the hard and woody part is totally separated from that which is soft and tender. This last, which is the true cortical substance, is divided into narrow, interlaced, or curled, of unequal size, and are exceedingly strong, and not apt to rot in the water.

**RHODIOLA, rosea-wort, a genus of the Caprifoliaceae order, in the Dioceta class of plants, and in the natural method ranking under the 13th order, succulent.** The male calyx is quadripartite, the corolla tetrapetalous. The female calyx is quadripartit and there is no corolla. The nectar is four; the pistils four; and the anthers four. There are two species, the rosea and the bibernata: the first grows naturally in the cliffs of the rocks and rugged mountains of China, and the Westfalia. It has a very thick fleshy root, which, when bruised or bruised sends out an odour like roses. It has thick succulent stalks, like those of the pine, about nine inches long, with thick succulent leaves united at the top. This shrub is terminated by a cluster of yellowish herbaaceous flowers, which have an agreeable scent, but are of short continuance. The second sort is a native of Cochlin China. Both species are easily propagated by parting their roots, and require a shady situation and dry unduged soil. The fragrance of the first species, however, is greatly diminished by cultivation.

**RHODODENDRUM, dwarf rose-bay, a genus of the monogynia order, in the decidua class of plants, and in the natural method ranking under the 18th order, becomes.** The calyx is quinqupartite; the corolla funnel-shaped; the stamens declinating; the capsule quinquelocular. There are nine species; the most remarkable of which are

1. The hirsutum, with asked hairy leaves, grows naturally on the Alps and several moun-

tains of Italy. It is a low shrub, which seldom rises two feet high, sending out many vigorous branches covered with a light-brown bark, and growing pretty close to the branches. They are hairy, having a great number of fine iron-coloured hairs on their edges and underside. The flowers are produced in bunches at the end of the wood, and usually one four scanty petal cut off into five oblong segments, and of a pale-red colour.

2. The fennugreek, with smooth leaves, hairy on their under side, is a native of the Alps and Apenines. It is a small shrub, and covered with barbed iron-coloured hairs, and grows upon rocks in cold and dry situations, and is seldom found near the sea. The bark is grey; the wood, as we have said, white, and when green, supple; but dries as soon as cut down. It becomes very light and brittle. This species is generally called upon grove, from the use to which the bark is applied by the inhabitants of the West Indies. This bark, which, from the great abundance of surface is easily detached when green from the wood, is beaten or bruised between two stones, until the hard and woody part is totally separated from that which is soft and tender. This last, which is the true cortical substance, is divided into narrow, interlaced, or curled, of unequal size, and are exceedingly strong, and not apt to rot in the water.

3. The chamissonis, or ciliated-leaved dwarf rose-bay, is a low deciduous shrub, native of mount Baldus, and near Salzburg, in Germany. It grows to the height of about a foot; the branches are numerous, produced irregularly, and covered with a purplish bark. The leaves are oval, spear-shaped, small, and in the under surface of the colour of iron. The flower is produced at the end of the branches in bunches, of a wheel-shaped figure, pretty large, of a fine crimson colour, and handsome appearance. They appear in July.

4. The dauriam, or Daurian dwarf rose-bay, is a low deciduous shrub, and native of Dauria. Its branches are numerous, and covered with a brownish bark. The flowers are wheel-shaped, large, and of a beautiful rose-colour; they appear in May, and are succeeded by oval capsules full of seeds, which in England do not always ripen.

5. The maximum, or American mountain laurel, is a deciduous shrub, and native of Virginia, where it grows usually on the sides of the highest mountains, and on the edges of cliffs, precipices, &c. where it reaches the size of a moderate tree, though with us it seldom rises higher than six feet. The flowers continue by succession sometimes more than two months, and are succeeded by oval capsules full of seeds.

6. The pectinum, or pontic dwarf rose-bay, is an evergreen shrub, native of the East, and of most shady places near Gibraltar. It grows to the height of four or five feet. The leaves are spear-shaped, glossy on both sides, and placed on short foot-stalks on the branches: the flowers, which are produced in clusters, are bell-shaped, and of a fine purple colour. They appear in July, and are succeeded by oval capsules, which in England seldom attain to maturity.

In Siberia, a species of this plant is used with great success in gouty and rheumatic affections; and the inhabitants of Siberia call it shrub, from which they take it for want of a common word to express it, as we do the Chinese plant of that name. This practice shows that the plant, used in small quantities, must be innocent.

**RHODORA, a genus of the decandria monogynia order, in the natural method ranking with those that are doubtful.** There is no calyx; the petals are four, oblong, obtuse, and narrowing at the base; the stamens are four, inserted in the corolla, and having large anthers; the seed-vessel unicellular, and contains one seed. There are only two species. The montana is a shrubly plant growing in Guiana, and remarkable for the great number of branches sent off from its trunk in every direction, and for the fetal smell of the wood and bark of this plant. The other is a native of Cayenne.

**RHOMBOIDES.** See Geometry.

**RHOMBIUS.** See Geometry.

**RHUBARB.** See Rheum, and Pharc.

**RHUMB, in navigation, a vertical circle of any given place, or the intersection of such a circle with the horizon; in which last sense rhumb is the same with a point of the compass.

**RHUM-B-LINE, is also used for the line which a ship describes when sailing in the same collateral point of the compass, or oblique to the meridians. See Navigation.**

**RIUS, sumach, a genus of the trigynia order, in the pentandria class of plants, and in the natural method ranking under the 43rd order, domose. The calyx is quinqupartite; the petals five; the berry monospermous. There are 33 species, of which the most remarkable are

1. The coriaria, or elms-leaved sumach, grows naturally in Italy, Spain, Turkey, Syria, and Palestine. The branches of this tree are used instead of oak-bark for tanning of leather; and it is said that the Turkey leather is all tanned with this shrub. It has a fig-like stalk, which divides at bottom into many irregular branches, rising to the height of eight or ten feet; the bark is hairy, of a herbaceous brown colour: the leaves are winged, composed of seven or eight pair of foliæ, terminated by an old one, blunted on their edges, hairy on their under side, of a yellowish-green colour, and placed alternately on the branches; the flowers grow in loose panicles on the end of the branches, which are of a whish herbaceous colour, each panicle being composed of several spikes of flowers sitting close to the footstalks. The leaves and seeds of this sort are used in medicine, and are esteemed very restringent in the stomach.

2. The typhulium, Virginian sumach, or vinegar-plant, grows naturally in almost every part of North America. This has a woody stem with many irregular branches, which are generally crooked and deformed. The young branches are covered with a soft velvety-like down, resembling greatly that of a young stag's horn, both in colour and texture, to which the species have given it the appellation of stag's horn. The leaves are winged, composed of six or seven pair of cal-

---

*Note: The text seems to be a mix of different sections, possibly from various botanical sources, and may not form a coherent whole.*
long heart-shaped lobes. The flowers are produced in close tufts at the end of the branches, and are succeeded by seeds, enclosed in purple woolly succulent covers, so that the branches are of a beautiful purple colour in a green hedge, and after they fall in autumn, change to a purplish colour at first, and before they fall to a feathery muri. It has got the name of the vinegar-plant from the double reason of the young greenish-garlic, which is terminated by producing either new or adding to the strength of old weak vinegar, whilst its ripe berries afford an agreeable acid, which might supply the place when necessary of the lime used for pickling. The powerful astrinency of this plant in all its parts recommends it as useful in several of the arts. As for example, the ripe berries baled with alum make a good dye for hats.

The plant being the natural successor of oak-bark in tanning, especially the white glove-leather. It will likewise answer to prepare a dye for black, green, and yellow colours; and with martial vitrul it makes a good paint. It flows from incisions made in the trunk or branches, makes, when dried, the basis of a varnish little inferior to the Chinese. Bees are remarkably fond of its flowers; and it abounds most of May in the flowering shrubs. The natives of America use the dried leaves as tobacco.

3. The glabrum, with winged leaves, grows naturally in North America. This is commonly called by the gardeners New England swinch. The stem of this is stronger and rises higher than that of the former; the branches spread more horizontally; the leaves, covered with greyish powdery wax, are also the foot-stalks of the leaves. The leaves are composed of seven or eight pairs of lobes terminated by an old one. The undersides of the lobes are of a dark green, and their under hairy but smooth. The flowers are produced at the end of the branches in very close panicles, which are large, and of a bright red colour.

5. The capsulina, or narrow-leaved swinch, grows naturally in many parts of North America, where it is known by the titles of beach swinch, probably from the place where it grows. This is of humber height even. The leaves are seldom rising more than four or five feet high in Britain, dividing into many spreading branches, which are smooth, of a light brown colour, with winged leaves, composed of four or five pairs of narrow leaves, Terminated by an old one. The leaves are of a light green on both sides. The flowers are produced in loose panicles at the end of the branches, of a yellowish herbaceous colour.

These are hardy plants, and will thrive in the open air here. The first and fourth sorts are not quite so hardy as the others, so must have a better situation, otherwise their branches will be injured by severe frost in the winter.

6. Besides these, Limnanthes has included in this genus the toxoodendron, or poison tree, under the name of rhois vernis, or poison-ash. This grows naturally in Virginia, Pennsylvania, New England, Carolina, and Japan, and is a strong woody stalk to the height of twenty feet and upwards; though in this country it is seldom seen above twelve, by reason of the plant's being extremely tender. The bark is brown, inclining to grey; the leaves are a compound of three or four pairs of lobes, terminated by an odd one. The leaves vary greatly in all the plant, but for the most part they are oval and spear-shaped. The foot-stalks become of a bright purple towards the latter part of summer, and in autumn all the leaves are of a beautiful purple before they fall off. All the species of sumach abound with an acid malleable juice, which is reckoned poisonous; but this property is most remarkable in the vernis.

The natives are said to distinguish this tree in the dark by its extreme coldness to the touch. The juice of some sorts of sumachs, when exposed to the heat of the sun, becomes so thick and clumsy, that it is used for bird-line, and the insipid juice of the poison-ash is said to be the fine varnish of the Chinese. The juice of the poison-ash, applied to the feet, is said by Hughes, in his Natural History of Barbados, to drive the vermin caused by the West Indians. The resin called gum sumach is from the rhois capsulina. See Corallia.

RHYME. See Poetry.
RHYTHMICAL, in music, an epitaph applied to the property or quality, in the antient melopoeia and modern melody, by which the cadences, accents, and quantities, are regulated and determined.

RIAL, or RIAL. See Coin.
RiAL, or RIAL. See Coin.
RIDELAND, or RIBBAN, a narrow sort of silk, chiefly used for head-ornaments, badges of chivalry.
RIBES, the currant and gooseberry-bush, a genus of the monogynia order, in the pen-tandria class of plants, and in the natural method ranking under the 47th order, stellate. The calyx is sepulchrate; the corolla monopetalous and sub-spherical; and there are three seeds. There is one species, a herb of Great Britain.
RICHIERIA, a genus of the class and order Dioscoria, pantanaria. The capsule is cotyled, six-valved, three-celled; seeds solitary; stile triphal. There is one species, a tree of the West Indies.
RICINUS, or PALMA CHRISTI, a genus of the monadelphia order, in the monadina class of plants, and in the natural method ranking under the 38th order, tricoceae. The male calyx is quinquipartite; there is no corolla, the staminodia are three. The female calyx is tripartite; there is no corolla, but three bifid styles, with a triocular capsule, and a single seed. There are six species, of which the most remarkable is the common, R. Christi. This tree is of speedy growth, and in one year it attains at its full height, which seldom exceeds twenty feet. The trunk is subglobeous; the pith is large; the leaves broad and palmated; the flower-spike is simple, and thickly set with yellow blossoms in the shape of a cone; the capsules are triangular and prickly, containing three smooth grey mottled seeds. When the fruits begin to turn black, they are gathered, dried in the sun, and the seeds picked.
out. They are afterwards put up for use as wanted, or for exportation.

Caster oil is obtained either by expression or by distillation. The first method is practised in England; the latter in Jamaica. It is common first to parch the nuts or seeds in an iron pot over the fire; but this gives the oil an empyreumatic taste, smell, and colour; and it is best prepared in the following manner: A large iron cast-iron of boil is first prepared, and half-filled with water. The nuts are then thrown in, boiling in pieces in deep wooden mortars, and after a quantity is beaten, it is thrown into the iron vessel. The fire is then lighted, and the larriq slowly but powerfully two hours, and kept constantly stirred. About this time the oil begins to separate, and swims on the top, mixed with a white froth, and is skimmed off till no more rises. The skimmed oil is set aside in a large barrel and strained through a cloth. When cold, it is put up in jars or bottles for use.

Caster oil, thus made, is clear and well flavoured, and if put into proper bottles will keep for years. The expressed or castor oil soon turns rancid, because the mucilaginous and acid parts of the nut are squeezed out with the oil. On this account the preference is given to well-prepared oil by decoction. A gallon of the seeds yields about two pounds of oil, which is a great proportion.

Before the disturbances in America, the planters imported train oil for lamps and other purposes about sugar-work. It is now found that the castor oil can be procured as cheap as the fish oil of America. It burns clearer, and has not any offensive smell. This oil takes all the colours of the painter, or for the apothecary in ointments and plasters. As a medicine, it purges without stimulus, and is so mild as to be given to infants soon after birth. All oils arenoxious to the skin, as castor oil, which makes easy to them. It is generally given as a purge after using the cabbage-bark some days.

The ricinus Americanus grows as tall as a little tree, and is so beautiful that Miller says it is a plant in every garden worth having, and he planted it himself in Chelsea. It expands into many branches; the leaves are sometimes two feet in diameter, and the stem as large as a middle-sized brown-staff; towards the top of the branch it has a cluster of flowers, somewhat resembling a bunch of grapes; the flowers are small and stigmatic, but on the body of the plant grow bunches of rough triangular hooks, each containing three speckled seeds, generally somewhat less than horsebeans; the shell is brittle, and contains white kernels of a sweet, oily, and nauseous taste. From this kernel the oil is extracted; and if the medicine should become official, the seeds may be imported at a reasonable rate, as the plant grows wild and in great plenty in all the British and French Antilles.

Of the ricinus communes, there are a great many varieties; all of them fine majestic plants, annual, or at most biennial, in this country; but in their native soil they are said to grow to the height of a tree. They are propagated by seeds sown on a hotbed, and require the same treatment as other tender exotics.

RICETTS. See INFANCY.

RICOTIA, a genus of the siliquose order, in the tetradynamia class of plants, and in the natural method ranking under the 30th order, siliqua. The siliqua is unilocular, oblong, and compressed, with thin valves. There is one species.

RIDING, in the sea language, is a term variously applied: thus, a ship is said to ride, when her anchors hold her fast, so that she does not drive by the force either of the wind or tide. A ship is said to ride across, when she is at anchor, her head or stern directed up to the hounds, and both yards and arms topped alike. She is said to ride well, when she is built so as not to overcast herself in a head-swat or ebb tide, nor to turn her from stem to stern. To ride athwart, is to ride with her side to the tide. To ride betwixt wind and tide, is to ride so that the wind has equal force over her one way, and the tide the other, and to have more power over the ship than the tide, she is said to ride wind-road, or to ride a great wind.

RIDING-CLERK, one of the six clerks in charge of a vessel; he is, in his turn, annually keeps the log, and publishes the control-loots of all books that pass the great seal that year.

RIESARME, in law, is a plan used in an account of debts or receivages of accounts, by which the defendant alights, there is nothing in arrear.

RIFLE, a fire-arm which has the inside of its barrel cut with from three to nine lines or grooves. The number of these grooves differs according to the size of the barrel and fancy of the workman. All these grooves are not regulated by any invariable rule.

Rides are said to have been known as far back as the middle of the sixteenth century. See Plate Riff, &c., fig. 1, which represents a cast taken of the inside of a rifled-barrel thirty inches long and $\frac{1}{2}$ of an inch in diameter, and in which the grooves take one turn in the whole length. It will of course be observed, that the ribs in the drawing represent the grooves in the rifle. The method of loading them is as follows:

When the proper quantity of powder (one drachm avariopeus) is put down at the muzzle, and a piece of calico or linen cloth is folded over it as a wad, a circular piece of strong calico is grooved on one side, and laid on the mouth of the piece with the grease side downwards; and a bullet of the right size as the bore of the piece, before the grooves were cut, being placed upon it, is then forced gently down the barrel with it; by which means, the calico includes the lower half of the bullet: and by its interposition between the bullet and the grooves, prevents the lead from being cut by them, and by means of the grease side down, without it being necessary to use any violent efforts, which would destroy the circular shape of the bullet.

In order to the cause of the superiority of a rifle-barrel gun over one with a smooth barrel, it will be necessary to refer to Mr. Robins's discovery of the cause of the irregularities which occur in the flight of shot, or smooth-bore balls, which we shall give in his own words, Tracts on Gunny, p. 156, &c.

Almost every projectile, besides the forces we have hitherto considered, namely, its weight, in this period of the air which directly opposes its motion, is affected by a third force which acts obliquely to its motion, and in a variable direction; and this consequently deflects the projectile from its rectilinear, and will be increased in that part of the plane in which it began to move; impelling it sometimes to one side, and sometimes to the other, occupying thereby very great intervals of the repeated ranges of the same piece,though each time found pointed in the same manner; and this force operating thus irregularly, I conceive to be the principal source of all that uncertainty and variability in the art of gunnery, which hath hitherto been usually attributed to the difference of powder. The reality of this force, and the cause which produces it, will, I hope, appear from the following considerations.

In order to the invariable character of shot, that no bullet can be discharged from the piece generally in use, without rubbing against its sides, and thereby acquiring a whirling motion as well as a progressive one. And as this motion is generated in the course of a whirling, if it can be conspire in some degree with the progressive motion, and in another part be equally opposed to it, the resistance of the air on the bare part of the bullet will be hereby affected, and will be increased in that part where the whirling motion conspires with the progressive, and diminished where it is opposed to it. And by this means the whole effect of the resistance would be made to act in a direction opposite to the direction of the whole body, will become oblique thereto, and will produce those effects already mentioned. If it was possible to predict the position of the axis round which the bullet should wind, and if that axis were unchangeable during the whole flight of the bullet, then the aberration of the bullet by this oblique force would be in a given direction, and the inaccuracy produced thereby would regularly extend the same way, from one end of its track to the other. For instance: if the axis of the wind were perpendicular to the horizon, then the deflection would be to the right or left; if that axis were horizontal, and perpendicular to the direction of the bullet, then the deflection would be upwards or downwards. But as the first position of this axis is uncertain, and the second may shift in the course of the bullet's flight, the elevation of the bullet is not necessarily in one certain direction, nor tending to the same side in one part of its track that it does in another; but if it usually is continually changing the tendency of its deflection, as the axis, round which it whirs, must frequently shift its position to the progressive motion by many inevitable accidents?
To prove the truth of his theory, Mr. Nobbs made the following experiments, before several members of the Royal Society:

"The first experiment, exhibited on this occasion, was to cause the whirling motion of a bullet, commencing with its progressive motion, to be diverted from that vertical plane, in which its motion began, by an increased resistance of what we asserted. Since no other power but that unequal resistance, which we here insist on, can occasion a body in motion to deviate from the vertical plane, in which it has once moved."

"Now by means of screens of exceedingly thin paper, placed parallel to each other at proper distances, this deflection in question may be many ways investigated. For by firing bullets which shall traverse these screens, the flight of the bullet may be traced out; and it may easily appear, whether they do or do not keep invariably to one vertical plane. This examination may proceed on three different principles, which I shall here separately explain.

"For first, an exact vertical plane may be traced upon all these screens, by which the deviation of any single bullet may be more readily investigated; only by measuring the distance of its hop forward, from the vertical plane thus delineated, and by this means the absolute quantity of its aberration may be known."

"Or if the description of such a vertical plane should be esteemed a matter of difficulty and nicety, a second method may be followed; which is that of resting the piece in some fixed notch or socket, so that the piece may have some little play to the right and left, yet all the lines, in which the bullet can be directed, shall intersect each other in the centre of that fixed socket; by this means, if two different shot are fired from the piece thus situated, the horizontal distances of the traces made by the two bullets on any two screens, ought to be in the same proportion to each other as the respective distances of these screens from the socket, in which the piece was fired. And if these horizontal distances differ from that proportion, then it is certain, that one of these shot at least hath deviated from a vertical plane, although the absolute quantity of its deviation cannot be with any certainty ascertained, because it cannot be known, what part of it is to be imputed to one bullet, and what to the other.

"But if the constant and invariable position of the notch or socket, in which the piece was placed, be not in doubt, an hypothesis in this very nice affair, the third method, and which is the simplest of all, requires no more than, that two shot be fired through three screens, without any regard to the position of the bullet at each time. For, in this case, if the shot diverge from each other, and both keep to a vertical plane, then if the horizontal distances of their traces on the first screen be in the same proportion to the zonal distances on the second and third, the two remainders will be in the same proportion with the distances of the second and third screen from the first. And if they are not in this proportion, then it will be certain, that one of them at least hath been deviated from the vertical plane; though here, as in the last instance, the quantity of that deflection in each will not be known."

All these three methods I have myself made use of at different times, and have ever found the success agreeable to my expectation. But what I thought the most eligible for the experiments, which I proposed to shew to this Society, was the employment of the two last, and the apparatus was as follows:

"On — being the first day appointed for these trials, the weather was unfavourable, and the experiments on that account more round than could have been wished, though they were far from inconclusive.

"But on the next Thursday two screens were set up in the large walk in the Charter-house garden; the first of them at 240 feet distance from the wall (which wall was to serve for a third screen), and the second two hundred feet from the same wall. And at fifty feet before the first screen, or at 300 feet from the wall, there was placed a large block, weighing about 200lbs. weight, and having fixed into it an iron bar with the socket at its extremity, in which the piece was to be laid. The piece itself was of a common length, and was bored for an ounce ball. It was each time loaded with a ball of 17 to the pound (so that the windage was extremely small) and with a quarter of an ounce of good powder. The screens were made of the thinnest tissu-paper, and the resistance they gave to the bullet (and consequently their probability of deflecting it) was so small, that a bullet firing one time near the extremity of one of the screens, left a short line of confusion on it towards the edge, which was so very weak, that it appeared difficult to handle it without breaking. These things thus prepared, five shot were made with the piece rest on the notch described above; and the horizontal distances between the first shot, which was taken as a standard, and the four succeeding ones, both on the first and second screen, and on the wall, measured in inches, were as follows:

1st screen 2nd screen wall
1 to 2 1,72 R 3,13 R 16,7 R
3 10, L 15,6 L 69,25 L
4 1,25 L 4,5 L 13,0 L
5 2,15 L 5,1 L 19,0 L

"Here the letters R and L denote, that the shot in question went either to the right or left of the iron bar.

"In the position of the socket in which the piece was placed, was supposed fixed (and I presume no person then present conceived, during these trials, that it could possibly vary the tenth of an inch from its first situation), then the horizontal distances, measured above the first and second screen, and on the wall, ought to be in the proportion of the distances of the 1st screen, the 2nd screen, and the wall, from the socket. But by only looking over these numbers, it will be found that none of them are in that proportion; the horizontal distance of the 1st and 3d (for instance) on the wall being nine inches more than it should be by this analogy.

"If without supposing the invariable position of the socket, we examine the comparative horizontal distances according to the third method described above, we shall in this case discover divergences still more extraordinary. For by the numbers set down above, the horizontal distances of the 2d and 3d shot on the two screens, and on the wall, are as under:
Here, if, according to the rule given above, the distance of the first screen be taken from the distances on the other two, the remainder will be 7 and 74,2; and these numbers, if each shot kept to a vertical plane, ought to be in the proportion of 1 to 3, that being the proportion of the distances on the second screen and of the wall from the first. But the last number 74,2 exceeds what ought to be by this analogy, by 39,7, so that in this there is a deviation from the vertical plane of above 39 inches, and this too in a transit of little more than eighty yards.

But further, to shew that these irregularities do not depend upon any accidental circumstances of the ball's fitting or not fitting the piece, there were five shot more made with the same quantity of powder and shot as before, but with smaller bullets, which ran much lesser in the piece. And the horizontal distances being measured in inches from the first to the bullet to each of the succeeding ones, the numbers were as follow:

<table>
<thead>
<tr>
<th>1st screen</th>
<th>1st screen</th>
<th>wall</th>
</tr>
</thead>
<tbody>
<tr>
<td>12.0</td>
<td>31.4</td>
<td>R</td>
</tr>
<tr>
<td>3.4</td>
<td>12.75</td>
<td>L</td>
</tr>
<tr>
<td>4.7</td>
<td>5.3</td>
<td>R</td>
</tr>
</tbody>
</table>

Here, again, on the supposed same position of the piece, the horizontal distance on the wall, between the first and third, will be found to be above fifteen inches less than it should be, if each kept to a vertical plane. And like irregularities, though small, do occur in every other experiment. And if they are examined according to the third method set down above, and the horizontal distances of the third and fourth, for instance, are compared, these on the first and second screen, and on the wall, appear to be thus:

<table>
<thead>
<tr>
<th>1st screen</th>
<th>2nd screen</th>
<th>wall</th>
</tr>
</thead>
<tbody>
<tr>
<td>22.5</td>
<td>38.5</td>
<td></td>
</tr>
</tbody>
</table>

And if the horizontal distance on the first screen is taken from the other two, the remainders will be 15.15 and 27.4; where the least of them, instead of being twice above the first, as it ought to be, is 23.35 short of it. So that here there is a deviation of above 23 inches.

From all these experiments the deflection in question seems to be incontestably evinced. But to give some further light to this subject, I took a barrel of the same bore with that hitherto used, and bent it at about three or four inches from its muzzle to the left, the bend making an angle of 3° or 4° with the axis of the piece. This piece, thus bent, was fired with a loose ball and the same quantity of powder hitherto used, the screens of the last experiment being still continued. It was natural to expect that if this piece was pointed by the general direction of its axis, the ball would be canted to the left of that direction by the barrel near its mouth. But as the bullet, in passing through that bent part, would, as I conceived, be forced to roll upon the right-hand side of the barrel; and thereby the left side of the bullet would turn up against the sin, and would give it a resistance on that side; I predicted to the company then present, that if the axis on which the bullet whirled did not shift its po-

Rifle.

sition after it was separated from the piece, then, notwithstanding the bend of the piece to the left, the bullet itself might be expected to deviate towards the right; and this, upon trial, did most manifestly happen. For one of the bullets fired from this bent piece, passed through the first screen about 14 inch distant from the trace of one of the shots fired from the barrel in the last set of experiments. On the second screen the traces of the same bullets were about three inches distant, the bullet from the crooked piece being still passing on both screens to the left of the other; but comparing the places of these bullets on the wall, it appeared that the bullet from the crooked piece, though it diverged from the track of the other on the two screens, had now crossed that track, and was deflected considerably to the right of that it was obvious, that, though the bullet from the crooked piece might at first be canted to the left, and had diverged from the track of the other barrel, with which it was compared; yet by degrees it deviated again to the right, and a little beyond the second screen crossed that track, from which it before diverged; and on the wall was deflected fourteen inches further, on the contrary side. And this experiment is not only the most convincing proof of the reality of this deflection here contended for; but is likewise the strongest confirmation, that it is brought about by the same cause, and by the very circumstances, which we have all along described.

To prevent this irregularity, rifled barrels are made use of; and here it happens, that, when the pieces are in the zone of the horizontal, the deflection of the bullet follows the sweep of the rifle; and thereby, besides its progressive motion, acquires a circular motion round the axis of the piece, which circular motion will be continued to the bullet, after its separation from the piece; by which means a bullet discharged from a rifled barrel is constantly made to whirl round an axis, which is coincident with the axis of the piece.

And it follows, that the resistance on the foremost surface of the bullet is equally distributed round the pole of its circular motion; and acts with as much force on every side of the line of direction, as to the same resistance can produce no deviation from that line. And (which is still of more importance,) if by the circular irregularity of the foremost surface of the bullet, or by any other accident, the resistance should be stronger on one side of the pole of the circular motion than on the other; yet, as the place, where this greater resistance acts, must perpetually shift its position round the line in which the bullet flies, the deflection, which this inequality would occasion, if it acted constantly with the same given tendency, is now continually retarded by the straining of contrary tendencies of that disturbing force, during the course of one revolution.

This perpetual correction of a deflactive effect on the foremost surface of the bullet, in consequence of the bullet round the line of its direction, may perhaps be exemplified, by considering what happens to a castle-top, whilst it spins upon its point. For it will be easily acknowledg'd that this continual revolution on its point could not for the least portion of time in that situation. And if we examine how this happens, we shall find, that, though the bullet itself is not exactly over the point it spins on, yet that inequality cannot instantly bring it to the ground according to the course of its motion; but, during one revolution, the centre of gravity of the bullet is at no time on every side of the top; and thereby it raises it as much in one place, as it depressed it in another. And this reasoning (supposing that the tendency of the centre of gravity of the top to descend, and being owing to the action of the unequal resistance on the topmost surface of a bullet fired from a rifled barrel) will easily explain how, notwithstanding that inequality, the bullet keeps true to its track without deflection. And what is here advanced, is further confirmed by the general practice with regard to arms, that it is well known to every archer, that the feathers of an arrow are placed in a spiral form, so as to make the arrow spin round its axis; without which it would be oblivious to the eye, that the arrow undulates in the air, and did not keep accurately to its direction. And the same principle, that every school-boy finds himself under the necessity of making his shuttlecock spin, before he can depend upon the truth of his effort, and lays down no one in twenty of these he could ever traced.

This may suffice as to the general idea of the form and convenience of a rifled piece; and here it will be expedient to insert some experiments, by which it will appear, how well it answers the purpose I have mentioned above; I mean that of keeping the ball to its regular track, by preventing that deflection, which, as we have seen, takes place in the bullets fired from common pieces.

And first, considered, that in consequence of the round about the manner in which it produces this defect; it is evident, that would follow, that the same hemisphere of the bullet which lies foremost in the piece, must continue foremost during the whole course of its flight.

To examine this particular, I took a rifled barrel carrying a bullet of six to the pound; but instead of its branded leaden bullet, I used a wooden one of the same size, made of a soft springy wood, which bent itself easily into the rifles without breaking. And, firing the piece thus loaded against a wall at such a distance, as the bullet might not be injured by the blow; I always found, that the same surface, which was foremost in the piece, continued foremost without any sensible deflection, during the time of its flight.

And this was easy to be observed, by examining the bullets, for the marks of the rifles, and the part that impinged on the wall, were sufficiently apparent.

Now, as these wooden bullets were but the mottled part of the weight of those of lead; I conclude, that effect, had been any unequal resistance or deflative power,
it effects must have been extremely sensi-
tive upon this light body; and consequently in a
proper perpendicular, so long as it only rises or
drops four degrees from the perpendicular, in
the direction of the wind; and, bringing it in
this situation, the bullet generally continued
about one fourth the height of the air, rising by
computation to near three quarters of a mile
perpendicular height.

"In these trials I found, that the bullet
commonly came to the ground to the key-
ward of the piece, and at such a distance from it, as nearly corresponded to its angle of
inclination, and to the effort of the wind;
usally falling not nearer to the piece than
a hundred, nor farther from it than a hundred
and fifty yards. And this is a strong con-
mofrmation of the almost steady flight of this
bullet for about a mile and a half. For were
the same trial made with a common piece,
I doubt not that the deviation would often
amount to half a mile, and perhaps consider-
ably more; though this experiment would be
a very difficult one to examine, on ac-
count of the little chance there would be of
discovering where the ball fell.

It now remains to speak of the sights,
which also affect the precision of the shot,
and which, in a certain degree, cannot consti-
tute a part of a rifle, as they may be applied
with a plain bored barrel; yet as that is
d seldom done, and as they are always used
with a rifle, it will not be proper to omit
mentioning them.

It may be strictly said, that no part of
the path of the bullet when fired from a rifle
or musket is in a right line, as gravity acts
upon the bullet the instant it quits the mouth
of the piece; and although at a short dis-
tance the effect is not very perceptible, yet
it is considerably so at 100 yards; and at
200 yards, the ball would probably strike
the ground before it could reach the object
aimed at, by the power of gravity alone.
In any case, it is found necessary to aim exactly at
such a height above the object, as the ball
would have been depressed by, by the power of
gravity, had it been aimed at it point-blank;
so that we suppose this depression to be a
foot in a hundred yards, we must aim a foot
above the object. But here another incon-
vienience arises; for if we aim above the
object by raising the muzzle of the piece,
the object is exsicated from our view by the
intervention of the barrel; so that we are
prevented from measuring the distance with
the eye, and instead of one, are liable to
aim two or three feet above the object.

This second difficulty is removed by de-
pressing the breech of the gun, instead of
elevating the muzzle; and the quantity of the
depression is measured with great nicety,
by what are called the "graduations" of the
piece, or the incline of the muzzle, at right
angles with its axis, is fixed a piece of flat
thin iron (see Plate fig. 3), about six inches
from the breech, and on the centre of its top,
as a scale or notch is filed. This is called the
back sight. The front sight is nothing more
than the small knob of iron or brass, which
is fixed on all bowing pieces, about half an
inch from the muzzle. When aim is taken,
the eye is raised over the back sight, till the
target or object, with the object B, which
is then brought upon the object, and forms
the right line ABCD, Plate fig. 2.

But here it is evident, that the breech of
the barrel is depressed in the proportion of
the angle of elevation of the line of sight or
BC; that the axis of the barrel forms an inclined plane with the
right line AEC; that the course of the
ball, if not acted upon by gravity, would be
in the line ECF; and that the ball would
strike at E, considerably above the object
D. But being depressed in its course by
the law of gravity, it will make the curve
H and descend to D.

By looking at the figure it is immediately
seen, that the object aimed at had been at
I, or any point nearer than D, the ball
would have passed over it; and if it had been
at K or farther than D, it would have passed
under it. The height of the back sight
must be regulated by experiment. The govern-
ment rifles have only one fixed sight, which
are intended for 200 yards; but if an enemy
is seen at 100 yards, aim must be taken at
the knee; if at 100 the head; and if at 250
yards, the head must be aimed at; and at
300, the sight becomes useless, as it would
be necessary to aim over his head, and then
the inaccuracy before mentioned recurs
to prevent which, three additional sights
are used as in figure 3, where the sight
A is calculated for 150, B for 200, and C for
300 yards; beyond which distance it be-
comes almost useless to fire at any object
of the size of a man.

Mr. Robinson, who has done more on this sub-
ject than any other person, concludes an ex-
cellent paper with predicting, that whatever state
shall thoroughly comprehend the nature
and advantages of rifled-barrel pieces; and have
facilitated and completed their con-
struction, shall introduce into their armies
their general use, with a dexterity in the
management of them; will by this means
acquire a superiority, which will almost equal
any thing that has been done at any time
by the particular excellence of any one kind
of arms; and will perhaps fall but little short
of the wonderful effect of the Huguenot
story relates to have been formerly produced, by
the first inventors of fire-arms.

RIGGING of a ship, is all her cargo
and ropes, belonging to her masts, yards, 
See Ship-build.

RIGHT, in geometry, signifies the same
with straight: thus a straight line is called a
right one.

Riot, in law, not only degrades
property, for which a writ of right lies, but also
any title or claim, either by virtue of a condi-
tion, mortgage, &c. for which no action
is given by law, but an entry only.

By statute, the Mar. cap. 2, the fol-
lowing particulars relating to the ill conduct
of king James II. were declared to be illegal,
and contrary to the ancient rights and liber-
ties of the people, viz. his exercising a power
for regulating his own laws; his levying money
without consent of parliament; violating the freedom of elections;
causing partial and corrupt jurors to be re-
turned on trial; and excessive bail to be taken,
and excessive fines to be imposed, as well
as cruel punishments to be inflicted, &c.

RIM, in a watch, or clock, the edge or
border of the circumference or circular part
of a wheel.

In some instruments of navigation and astronomy, a
brass instrument, made in the form of a ring,
and serving to take the altitudes of the sun. See
Plate Mosei. cap. 290.

At C is a small hole, in the direction CD,
which is perpendicular to E, and is this distance
DE, parallel to the vertical diameter AB. From C, as
a centre, they describe a quadrant of a circle
CED; which being nicely divided into 90°,
or subdivided upon the inner surface of the
ring the places where rays, drawn from C to
these degrees, cut the said surface.

To use this ring, they hold it up by the
sized, and turn the side with the hole C
towards the sun; and then the sun-beams
passing through the hole, make a luminous
spot among the degrees, whereby the alti-
dude is found. Some prefer the ring to the
astrolobe, by reason its divisions are larger;
however, it is far from being exact enough
to be much depended on in astronomical
observations, which are better made by quad-
drants. See Astrolabe, and Quadrant.

RIOT, in law. When three persons
or more shall assemble themselves together,
with an intent mutually to assist one another,
against any who shall oppose them in the
execution of some enterprise of a private
nature, with force or violence, against the
peace, or to the manifest terror of the people,
which enterprise is of an unlawful, riotous,
or unlawful; if they only meet for such a
purpose or intent, though they shall after
depart of their own accord without doing any
thing, this is an unlawful assembly. 1 Haw.
135.

If after their first meeting, they shall move
forwards towards the execution of any such
act, whether they put their intended pur-
pose into execution or not; this according to
the general opinion is a riot. Id.

By 34 Ed. Ire. c. 1, it is enacted, that if
a justice finds persons riotously assembled,
he alone has not only power to arrest the
offenders and hindering any unlawful be-
aviour, or imprison them if they do not
offer good bail; but he may also authorize
others to arrest them, by a bare verbal com-
mand, without other warrant; and by force
thereof, the persons so commanded, may pur-
sue and arrest the offenders in his absence as
well as presence. It is also said, that after
any riot is over, any one justice may send
his warrant to arrest any person who was
concerned in it, and that he may send him
goad till he shall find sureties for his good
behaviour. 1 Haw. 160.

The punishment of unlawful assemblies, if
to the number of twelve, may be capital,
according to the circumstances which attend
them; but from the number of three to
eleven, is by fine and imprisonment only.

The same is the case by riots and routs by
the common law, to which the pillory in very
numerous cases has been sometimes super-
added. 4 Black, c. 11.

By stat. 1 Geo. I. cap. 5, if any persons
who to the number of twelve or more, unlawfully
and riotously assembled, continue together
for an hour, after being required, by a justice
of the peace, or other magistrate, to disperse
they shall be deemed guilty of felony without
benefit of clergy. However, prosecutions
upon this statute must be begun within one year after the offence is committed.

Rivers, as every body has seen, are always broadest at the mouth, and narrower towards their springs; but this is less known; and, probably more deserving curiosity, is, that they run in a more direct channel as they immediately leave their sources; and that their divisures and turning become more numerous as they proceed.

It is a certain sign among the native Ezrians, that they are near the sea, when they find the rivers widening, and every now and then changing their direction. And this is even now believed by the Europeans themselves, in their journeys through those trackless forests.

As those inundations, therefore, increase as the river approaches the sea, it is not to be wondered at, that they sometimes divide and thus disambiguate by different channels. The Dnieper is divided amongst the Euxine by seven mouths; the Nile, by the same number; and the Wolga, by seventy.

The largest rivers of Europe are, first, the Wolga, which is about six hundred and fifty leagues in length, extending from Reschow to Astrachan. It is remarkable of this river, that it abounds with water during the summer months of May and June; but all rest of the year is so shallow as scarcely to cover its bottom; or, allow a passage for loaded vessels that trade up its stream. The next in order is the Danube. The course of this is about four hundred and fifty leagues, from the mountains of Switzerland to the Black Sea. The Don, or Tanais, which is four hundred leagues from the source of that branch of the Volga called Sofiana, to its mouth in the Euxine Sea. In one part of its course it approaches near the Wolga; and Peter the Great had actually begun a canal, by which he intended joining those two rivers; but this he did not finish. The Niépr, or Borysthones, which rises in the middle of Muscovy, and runs the course of three hundred and fifty leagues, to empty itself into the Black Sea. The Old Cossacks inhabit a great part of this river; and frequently cross the Black Sea, to plunder the maritime places on the coasts of Turkey.

The Dvina, which takes its rise in a province of the same name in Russia, that runs a course of three hundred and fifty leagues, and discharges into the White Sea, a little below Archangel.

The largest rivers of Asia are, the Hwang-ho, in China, which is about eight hundred and fifty leagues in length, coming from its sources at Hsia Li, and joining the Tsze Lien, in the mouth of the Gulph of Ching. The Jénisea of Tartary, about eight hundred leagues in length, from the lake Schling to the icy Sea. This river, by some, supposed to supply most of that great quantity of drift-wood which is seen floating in the seas, near the Arctic circle. The Oby, of five hundred leagues, running from the lake of Kila into the Northern Sea. The Amour, in Eastern Tartary, whose course is about five hundred and seventy-five leagues, from its source to its entrance into the sea of Kalla. The Kuan, in China, five hundred and fifty leagues in length, The Ganges, one of the most noted rivers in the world, and about as long as the former. It rises in the mountains which separate India from Tartary, running through the dominions of the Great Mogul, discharges itself by several mouths into the bay of Benga.

It is not only esteemed by the Indians for the depth and pureness of its streams, but for a supposed sanctity which this appears to be in its waters. It is visited annually by several hundred thousand pilgrims, who pay their devotions to the river as to a god; for savage simplicity is always known to mistake the blessings of the Deity for the Deity himself; and when the temples, or shrines, are built, of distant countries, to expiate for all kinds of sins, and to be buried in its stream. The water is lowest in April or May; but the rains beginning to fall soon after, the flat country is inundated by that season. It is said about the end of September; the waters then begin to retire, leaving a prolific sediment behind, that enriches the soil, and, in a few days time, gives a luxuriance to vegetation, beyond what can be conceived by an European. Next to this may be reckoned the still more celebrated river Euphrates. This rises from two sources, north and south of the city Erzewan, on the Turcomania; and unites about three days journey below the same, whence, after performing a course of five hundred leagues, it falls into the Gulph of Persia, fifty miles below the city of Bassora in Arabia. The river bas in extended, from its source to its discharges into the Arabian sea, four hundred leagues.

The largest rivers of Africa are, the Senegal, which runs a course of not less than five thousand leagues, comprehending the Nile, which some assert is so large as to fall into it. Later accounts, however, seem to confirm that the Niger is lost in the sands, about three hundred miles up from the western coast of Africa; but it may, the Senegal is well known to be navigable for more than three hundred leagues up the country; and how much higher it may reach is not yet discovered, as the dreadful fatality which often occurs in its mouths, only deter the curiosity, but even avarice, which is a much stronger passion. The celebrated river Nile is said to be nine hundred and seventy leagues, from its source among the mountains of the Moon, or Upper Egypt, to its opening into the Mediterranean Sea. Upon its arrival in the kingdom of Upper Egypt, it runs through a rocky channel, which some river travelers have mistook for its cata
cracts. In the beginning of its course, it receives many lesser rivers into it; and Pliny was mistaken, in saying that it received none. In the beginning also of its course, it cuts across the rock of rubies, below three hundred leagues from the sea, runs in a direct line. Its annual overflows arise from a very obvious cause, which is almost universal with the great rivers that take their source near the Lane. The rainy season, which is periodical in those climates, floods the rivers; and as this always happens in our summer, so the Nile is at that time overflowed. From these inundations the inhabitants of Egypt derive happiness and plenty; and, when the river does not arrive at its accustomed height, they prepare for an indifferent harvest. It begins to overflow about the 17th of June. Thus thinks he it should be for forty days, and decrease and increase about as much more. The time of increase and decrease, however, is much more indifferent now than it was among the ancients. Berossus, in the history of Africa says, that a hundred days rising, and as many falling; which shows that the inundation was much greater at that time than at present. M. Buffon has ascribed the present diminution, as well to the lessening of the mountains of the Moon, by their substance having so long been washedrounded by the continual friction of the winds, and the rapidity of the sea. On the side of tableland, these winds blow in a contrary direction; and, for that reason, the climate of the interior of Africa is equable.
down with the stream, as to the rising of the earth in Egypt, that has for so many ages received this extraneous supply. But do not find, by the buildings that have remained since the times of the antients, that the earth is much raised since then. Besides the Nile in Africa, we may reckon Zara, and the Coamza, from the greatness of whose openings into the sea, we may imagine, if these streams, we form an estimate of the great distance whence they come. Their courses, however, are spent in watering deserts and savage countries, whose poverty or fences have kept strangers away.

But of all parts of the world, America, as it exhibits the most lofty mountains, so also it supplies the largest rivers. The principal of these is the great river Amazon, which, from its source in the lake of Lauiticochi, to its discharge into the Western ocean, performs a course of more than twelve hundred leagues. The width and depth of this river is answerable to its vast length; and, where its width is most contracted, its depth is augmented in proportion. So great is the body of its waters, that other rivers, though before the object of the Rille during the summer. It proceeds after their junction, with its usual appearance, without any visible change in its breadth or ripidity; and, if we may so express it, remains great without ostentation in some places it displays its whole magnificence, dividing into several large branches, and encompassing a multitude of islands; and at length, discharging itself into the ocean, by a channel of an hundred and fifty miles, and above thirty feet in depth. This great river, that may almost rival the former, is the St. Lawrence, in Canada, which rising in the lake Asiniobolus, passes from one lake to another, from Christiano to Aleppo; and thence to lake Superior; thence to the lake Hurons; to lake Erie; to lake Ontario; and, at last, after a course of nine hundred leagues, pours their collected waters into the Atlantic Ocean. The river Mississippi is more than seven hundred leagues, commences at a source near the lake Asiniobolus, and ending at its opening into the Gulf of Mexico. The river Plata runs a length of more than eight hundred leagues from its source, in Paraguay, to its mouth. The river Oroonoko is seven hundred and fifty leagues in length, from its source near Pusto, to its discharge into the Atlantic ocean.

Such is the amazing length of the greatest rivers; and even in some of these, the most remote sources very probably yet continue unknown. In fact, if we consider the number of rivers which they receive, and the little acquaintance we have with the regions through which they run, it is not to be wondered at that geographers are divided concerning the source of many of them. As among a number of roots by which nourishment is conveyed to a stately tree, it is difficult to determine precisely that by which the tree is chiefly supplied; so among the branches of a river, it is even more difficult to tell which is the original. Hence it may easily happen, that a similar branch is taken for the capital stream; and its runnings are pursued and delineated, in prejudice of some other branch that better deserves the name and the description. In this manner, in Europe, the Danube is known to receive thirty lesser rivers; the Volga or thirty-three. In Asia, the Ilo- latino receives thirty-five; the Jenise above sixty; the Oly as many; the Amour about forty; the Nauquin receives thirty rivers; the Ganges twenty; and the Euphrates about twenty. In Africa, the Senegal receives more than twenty rivers; the Nile receives not one for five hundred leagues; and, then only twelve or thirteen. In America, the river Amazon receives above sixty, and they are of considerable size; the river St. Lawrence about forty, counting those which fall into its lakes; the Mississippi receives forty; and the river Plata above fifty.

The inundations of the Ganges and the Nile have been already mentioned, and it might be added, that almost all great rivers have their periodical inundations from similar causes. The author already quoted observes, that, besides these annually periodical inundations, there are many rivers which overflow at intervals. Thus most of those in Peru and Chili have scarce any motion by night; but upon the appearance of the morning sun they assume their former rapidity; this proceeds from the rains, which, melting with the heat, increase the stream, and continue to drive on the current while the sun continues to dissolve them.

There are some rivers which are said to lose themselves in channels under the earth, and to flow for several miles in secret and undiscovered channels. On this circumstance is founded one of the most beautiful fables of antiquity, relative to the fountain of Arethusa, in Sicily. The same thing is affirmed of the Rhine, and even of the river Mole, in Surrey, which, from this circumstance derives its name. With respect to the two latter rivers, however, some doubts are entertained of the fact.

On this subject there is a memoir of the academy of sciences, written by M. Guettard. "It is very surprising (he observes) if we reflect on it, that a river in its course, which is very often very extensive, should not meet with spongy soils to swallow up its waters, or gently drain them into the sea; nevertheless, there has been hitherto known but a small number of rivers whose waters thus disappear, this phenomenon has been accounted very extraordinary, both by the ancients and moderns. M. Guettard next describes what he has observed in several rivers of Normandy, which are lost and afterwards appear again; these are five in number, viz. the Rille, the Ithon, the Aure, the river of Sep-Audé, and the Drôme. The three first disappear gradually, and then come in sight again; the fourth loses itself entirely by degrees, but afterwards re-appears; the fifth loses some of its water in its course, and ends by precipitating itself into a cavity, whence it is never seen to rise again.

What seems to occasion the loss of the Rille, the Ithon, and the Aure, is the nature of the soil through which they pass. M. Guettard has observed that it is in general porous, and that, as it is impermeable, the cavities of which are not well compacted together; it sinks suddenly down by its own weight in some places, and there forms great holes; and when the water overflows the meadows, it frequently makes many cavities in several parts of them. If we therefore suppose inequalities in the channels of these rivers, and that there are certain places in which the water stagnates or sinks to the earth, it must there dilate the ground, if we may use that expression; and having carried away the parts which unite the grains of sand together, those grains will become after- wards no other than a kind of sponge, in which the waters will infiltrate themselves, provided nevertheless that they find a passage under ground through which they may run. This conjecture appears to be so well founded, that each of these three rivers loses itself nearly in the same manner, that is, through cavities which the people of the country call beitors, and which swallow up more or less according to their largeness. M. Guettard, who has carefully examined them, remarks, that besides the sandy soil of a tunnel, whose diameter and aperture is at least two feet, and sometimes exceeds eleven; and whose depth varies in manner from one and two feet, to five, six, and seven feet; the cavity sometimes loses almost all its water in the space of two short leagues; the Ithon does very near the same. But M. Guettard observes something curious concerning this river, that formerly did not receive a name, kept its course without any interruption, as appears by the history of the country; very likely the mud, which had been collected together in several parts of its channel, might have occasioned the said cavities under ground through which it may take its course. M. Guettard seems also much inclined to believe, that there are, in these parts, subterraneous cavities through which the waters may flow; and in consequence of this he reports a number of facts, all tending to prove the truth of it, or at least to prove that there must be hollow quarries serving for strainers to these waters. Upon which occasion he goes into a discussion of this question: Are the subterraneous rivers, and is the proposition of some persons in favor of this particular well founded? He makes it appear by several instances which he quotes, and by many reasons which he alleges, that there are at least very great presumptions in favor of this opinion. We are too apt not to look beyond the exterior of things: we feel resistance upon the surface of the earth; when we go deep, we often find it. This is therefore hard for us to imagine that it cannot contain subterraneous cavities sufficient to form channels for hidden rivers, or for any of their branches.
considerable body of water; in a word, that it can contain vast caverns; and yet every thing seems to indicate the contrary. A fact that forms the subject of the Riff, concerning which we have spoken, and particularly of the Riffe, proves in some measure that there are considerable lakes of water in the mountains which limit its course; this fact is, that in winter the greater part of their basins become springs, which supply the river's channel with as much water as they had absorbed from it during the summer. Now from whence can that water come, unless from the reservoirs or basins, that are inclosed in the mountains, which being lower than the river in summer, absorb its water, and being higher in winter by the rain they receive, send it back again in their turn?

M. Guettard strengthens this conjecture by several instances that render it very probable: he remarks at the same time, that this alternate effect of the betoires swallowing up the water and restoring it again, causes prings an invisible obstacle to the recesses of water within the channel of the river. It has indeed been several times attempted to stop those cavities; but the water returns with such violence in winter, that it generally carries away the materials with which they were stopped.

The river of Sap-André is lost in part, as we have before said, in the same manner as the Lhôn and the Riffe; but there is something more remarkable in it than in those rivers, to wit, that, at the extremity of its course, where there is no perceptible cavity, it is ingulphed, but without any fall; the water passes between the pebbles, and it is impossible to force a stick into that place any further than into the betoires of which we have spoken. What makes this river take that subterraneous direction, is an impediment which its stream meets with in that place; it is there stopped by a rising ground six or seven feet high, whose bottom it is very likely that the surface of a fresh water will be, and that, having been able to make its way over it. At some distance it appears again; but in winter, as there is a greater quantity of water, it passes over that eminence, and keeps an undisturbed course, till it discharges itself into the Dronc, after having lost some of its water in its course, vanishes entirely near the pit of Sancy; in that place it meets with a sort of subterraneous cavity near 25 feet wide, and more than 13 deep, where the river is in a manner stopped, and into which it enters, though without any perceptible motion, and never appears again.

M. Guettard finishes this memoir with some observations upon the ferre. This river is lost in the same manner as the Riffe; and though it is very near Paris, this singular fact is unknown to almost every body; was it not for the account of M. l'Abbé le Bœuf, M. Guettard would have been also ignorant of it. And as he thinks the chief object of a naturalist ought to be to collect, examine, and communicate to every body, he examines the means which might be employed to restrain the water of the ferre. The same object has made him add a description of the manner how the River of Sap-André, or natural springs, bear no currents disturbed; for it is now very certain that it does not lose itself, but that its channel is extremely confined, in the place where it was pretended that it lost itself, by two or three feet of water at the foot. M. Guettard makes it appear that it might not be impossible to widen that place, and give a sufficient channel to the river, which would render it navigable, and be of vast utility to all the country.

The many advantages which accrue to a country from an abundance of rivers, especially large navigable ones, are too obvious to require any particular detail; but the disadvantages and calamities occasioned by them are frequently more conspicuous and fatal. Whole tracts of countries are sometimes Overflowed on a sudden, and every thing swept away at once; or if the deluge proceeds not such a length, yet by the quantity of stagnating water which is left, marshes are produced, which bring on diseases in the neighboring parts. It becomes therefore an object well worthy the public attention, how to secure the banks of rivers, or to form their channels in such a manner that the stagnant water may be carried off into the ocean without producing the mischievous effects abovementioned. In a treatise on rivers and canals published in the Phil. Trans., Mr. Smith, the subject at length. Having laid down a number of theorems concerning the descent of the water in rivers, he points out a method of determining whether the motion of the water in a particular place is from the inclination of the bottom of its channel, or merely from the pressure of the upper parts of the water upon the lower. "For this purpose," says he, "a pole must be thrust down to the bottom, and held perpendicularly to the current of the water, with its upper end above the surface; if the water swells and rises immediately against the pole, it shows that its flowing is by virtue of a preceding declivity; but, on the contrary, the water stops for some moments before it begins to rise against the pole, it is a proof that it flows by means of the compression of the upper waters upon the lower."

This is the simple method of measuring the velocity of the current of a river, according to our author, is as follows: "Take a cylindrical piece of dry light wood, and of a length something less than the depth of the river; and, having prepared it, let there be suspended as many small weights as may be necessary to keep up the cylinder in a perpendicular situation in the water, and in such a manner that the other end of it may just appear above the surface of the water. Fix to the centre of that end which appears above water a small and straight rod precisely in the direction of the cylinder's axis; to the end that, when the instrument is suspended in the water, the deviations of the rod from a perpendicularity to the surface of it may indicate which end of the cylinder advances the fastest, whereby may be discovered the different velocities of the water at different depths; for if the rod inclines forward, it is evident that the direction of the current, it is a proof that the surface of the water has the greatest velocity; but if it inclines back, it shows that the swiftest current is at the bottom; if it remain perpendicular, the velocities at the surface and bottom are equal.

"This instrument being placed in the current of a river or canal receives all the perceptions of the water throughout the whole depth and will have an equal velocity with that of the whole current from the surface to the bottom at the place where it is put in; and by that means may be found, both with ease and exactness, the mean velocity of that part of the river for any determinate distance and time."

"But to obtain the mean velocity of the whole section of the river, the instrument must be put successively both in the middle and towards the sides, because the velocities at these places are extremely different from each other. Having by this means found the difference of time required for the currents to run over an equal space, or the different distances run over in equal times; the mean proportional of all these trials, which is found by dividing the common sum of them all by the number of trials, will be the mean velocity of the river or canal."

"If it is required to find the velocity of the current only at the surface, or at the middle, or at the bottom, a sphere of wood, of such a size as may be suspended in equilibrium with the water at the surface or depth which we want to measure, will be better for the purpose than a cylinder, because it is only affected by the water of that part of the current where it remains suspended.

It is a very easy guide both to the cylinder, and the globe in that part which we want to measure, by means of two threads, or small cords, which two persons must hold and direct, one on each side of the river; taking care at the same time neither to retard nor accelerate the motion of the instrument."

Our author next proceeds to deduce from his theory the best methods of removing the defects and inconveniences which must necessarily happen to rivers and canals in a series of years. From his theory he draws the following conclusion: that the deeper the waters are in their bed in proportion to its breadth, the more their motion is accelerated; so that their velocity increases in an inverse ratio of the breadth of the bed, and also of the greatness of the section; whence are deduced the two following universal principles. 1. The velocity of water in a river or canal, without augmenting the declivity of the bed, we must increase the depth and diminish the breadth of its bed. 2ly. But to diminish the velocity of water in a river or canal, we must, on the contrary, increase the breadth and diminish the depth of its bed.

The above proposition is perfectly conformable to observation and experience: for it is constantly seen, that the current is the swiftest where the waters are deepest and the breadth of the bed the least, and that they flow slowest where their depth is the least and the breadth of the bed the greatest. The velocity of the waters," says M. de Buffon, "augments in the same proportion as the section increases through which they pass diminishes, the force of impulsion from the back waters being supposed always the same. Nothing," continues he, "produces so great a diminution in the swiftness of the waters, and makes them so slow as to cause the contrary, the increase of the volume of water augments its velocity more than any.
The celebrated Wolfe in his hydraulics assures us, that "it is a constant and universal practice, for accelerating the current of waters, to deepen the bed, and at the same time to render it narrower. When the velocity which a river has acquired by the elevation of its springs and the impulse of the back water, is at last totally destroyed by the different causes of resistance, becoming exactly equal to, or greater than, the first, the bed and current at the same time being horizontal, nothing else remains to propagate the motion, except the sole perpendicular compression of the upper waters upon the lower, which is always in a direct ratio of their depth. But this necessary resource, this remaining cause of motion in rivers, augments in proportion as all the others diminish, and as the want of it increases; for as the waters of rivers in extensive plains lose the acceleration of motion acquired in their descent from their springs, their quantity accumulates in the same bed by the junction of several streams together, and their depth becomes consequently immense. This junction increases the accumulation of many streams in the same bed, which we see universally in a greater or lesser degree in all rivers throughout the known world, and which, in a measure, corresponds with the diminution of their waters, usually attributed, says Signor Guiglielmin, to the infinite wisdom of the supreme Author of Nature. The velocities of flowing waters is very far from being in proportion to the quantity of velocity of the bed. If it was a river whose velocity is uniform and double to that of another, it ought only to run with double the swiftness when compared to it; but in effect it is found to have a much greater, and its rapidity, instead of being only double, will be triple, quadruple, and sometimes even more; for its velocity depends much more on the quantity and depth of the water, and on the compression of the upper waters on the bottom, than the swiftness of the bed. Consequently, whenever the bed of a river or canal is to be dug, the declivity must not be distributed equally throughout the whole length; but, to give a wider current to the declivity, it must be much more in the beginning of its course than towards the end where it disengages itself, and where the declivity must be almost insensible, as we see is the case in all natural rivers; for when they approach near the sea, their declivity is little or nothing; yet they flow with a rapidity which is so much greater, as they contain a greater volume of water; so that in great rivers, although a large extent of their bed should be absolutely horizontal, and without any declivity at all, yet their waters do not cease to flow, and to flow even with great rapidity, both from the impulsion of the back-waters, and from the compression of the upper waters upon the lower in the same section. Whosoever is well acquainted with the principles of the higher geometry, will easily perceive that it would be no difficult matter to dig the bed of a canal or river, but that the velocity of the current should be everywhere equal. It would be only giving it in the form of a curve along which a moving body should recede from a given point, and describe spaces everywhere proportional to the times, allowance being made for the quantity of effect of the compression of the upper waters upon the lower. This curve is what is called the horizontal isochrone, being the natural and mean and mud, etc., most necessary higher proportionately the free running off of the water; for it is evident, that the waters so far back from these obstacles, until the horizontal level of the bottom of the bed becomes higher than the top of the obstacles, must be entirely kept up and hindered from running off in proportion. Now as the waters must continue to come down from their sources, if their free running off is hindered by any obstacles whatever, their relative height back from them must necessarily be increased until their elevation, combined with the velocity of their current proceeding from it, is arrived to such a pitch at the point where the obstacles exist, as to counterbalance the pressure and the impediment proceeding thence, which frequently does not happen until all the lower parts of the country round about are laid under water. Now it is certain from all experience, that the beds of rivers and canals in general are subject to some or other of the obstacles above-mentioned. It rocks or trees do not bar their channels, at least the quantity of their waters, and hence the streams never fail to bring down, particularly in floods, and which are usually deposited according to the various windings and degrees of swiftness in the current, must unavoidably, in course of time, fill up, in part different places in the channel, and hinder the free running off of the back-waters. This is certainly the case, more or less, in all rivers, and in all canals of long standing, as is notorious to all those well acquainted with them. Hence, if these accidents are not carefully and with a constant attention prevented, inundations occur which sometimes lay waste whole districts, and ruin the finest parts of the land. Rivers with sand, hence rivers become unavailing, and canals useless for the purposes for which they were constructed. Canals, in particular, as their waters for the most part remain stagnant in them, are still more liable than rivers to have their beds fill up by the subsiding of mud, and that especially for some distance above their sluices; insomuch that if continual care is not taken to prevent it, or usually it is often long after, they will soon become incapable of receiving and passing the same vessels as formerly. Nay, the very sluices themselves, if the floors of their bottoms are not of a depth conformable to the bed of the canal, will produce the same accidents as those we have been speaking of; for if they are placed too low, they will be continually filling up with sand or mud; if too high, they have the same effect as banks or lands in rivers, that is, they will collect all the back-waters under their level from running off, and soon fill up the bed to that height by the subsiding of mud. This effect is much accelerated by the shutting of the lower sluices, which makes a great volume of water rush up to those next above them, fill the whole is filled and become stagnant. Now it is evident, that this state of things must contribute far more to the subsidity of mud, and all other matters brought in by the current, than can be the case in rivers whose currents constantly flow.

The waters of all rivers and canals are from time to time muddy; their streams, particularly during rains and floods, carry along with them earth and other substances, which are compelled by the current to run into the dikes, and to make the lower waters of the rivers and canals, or into the lands, the back-waters, and the bottom of the dikes. This is not to be discovered, because the waters of the lower reaches are usually found in a station of water, much above high-water mark of the sea. On the contrary, the rivers and canals are only susceptible of being cleared of their mud and sand, when the water is full or high, and on the contrary, the water of the lowest waters is never clear in the sea, or in other waters. The water in the rivers and canals is generally, in most canals and rivers, much higher than the seas. The reason of this is, that the rivers and canals receive and collect from all the surrounding district, and discharge into the sea. This is a very remarkable thing, which the engineer and hydraulicist often observes, that the water in the rivers and canals is always higher than the seas and the ocean, and that the water in the canals is always higher than the rivers. This is the case in all countries, and particularly in the countries of Holland and Flanders, where the canals are very high, and the rivers and canals are much higher than the seas. This is the case in all countries, and particularly in the countries of Holland and Flanders, where the canals are very high, and the rivers and canals are much higher than the seas. This is the case in all countries, and particularly in the countries of Holland and Flanders, where the canals are very high, and the rivers and canals are much higher than the seas.
RIVERS.

bed of the canal below the horizontal level of the bed of the sluice will serve to no manner of purpose, either for navigation, or for carrying off the back-waters, but will soon fill up with mud, in spite of all means used to the contrary, except that of digging it continually anew to no manner of purpose.

Setting off from this determined point, at the mouth of a river, or at the bottom of the last sluice upon a canal, which are to be cleaned and deepened, the work must be carried on, in consequence uniformly throughout the length of the sluices backwards, into the country as far as is found necessary for the purposes intended. This is to be done after the following manner:

1st. One must dig up and carry away all windings, and bed of the canal below the horizontal level of the bed of the sluice will serve to no manner of purpose, either for navigation, or for carrying off the back-waters, but will soon fill up with mud, in spite of all means used to the contrary, except that of digging it continually anew to no manner of purpose.

2dly. If the declivity of the bed should be still too little to give a sufficient current to carry off the water as often and as fast as is necessary, the whole bed itself must be regularly deepened, and what is dug out from the bottom or sides of the channels, to render it narrower in proportion to its depth.

3dly. Wherever the banks are too low to contain the stream in all its situations, they must be sufficiently raised; which may be conveniently done with what is dug out from the bed; and the whole being covered with turf will render these banks firm and solid against the corrosion of the water. It is proper at all times to lay upon the banks what is dug from the bed, by which they are continually strengthened against the force of the current.

4thly. It is often necessary to diminish the windings and sinuosities in the channel as much as possible, by making new cuts whereby its course may approach towards a right line. This is a great resource in flat countries subject to inundations; because thereby all the declivity of a great extent of the river, and all the windings, may be thrown into a small space by cutting a new channel in a straight line; as may generally be done without obstacle in such countries as we are speaking of, and hereby that the current will be very greatly augmented, and the back-waters carried off to a surprising degree.

5thly. Wherever there is a confluence of rivers or canals, the angle of their junction must be made as acute as possible, or else the worst of consequences will arise from the corrosion of their respective streams; what they carry off from the sides will be thrown into irregular banks in the bottom of the bed. This acute angle of the junction must be neither too much or too little by taking the direction at some distance from the point of confluence.

6thly. Wherever the sides or banks of a river are liable to a more particular corrosion, from the confluence of streams, or from irremediable windings and turns in the channel, they must be secured against it as much as possible by weirs: for this corrosion not only destroys the banks, and alters the character of the river, but also fills up the bed, and produces all the bad effects we have spoken of above.

7thly. If the principal and greatest attention in digging the beds of rivers and canals is directed to the quantity and form of their declivity. This must be done uniformly throughout their whole extent, or so much of it as is necessary for the purposes in hand, according to the principles laid down of securing the form of the windings, their beds, and of the floors of their sluices, at the mouths where they discharge their waters, being fixed, the depth of the rest of the beds, and the quantity of declivity, must be regulated in consequent order as to increase regularly the quantity of the declivity in equal spaces the further we recede from their mouths, and proceed towards their sources or to the part where the regular current is to take place.

If the depth and volume of water in a river or canal is considerable, it will suffice, in the part next the mouth, to allow one foot perpendicular of declivity through six, eight, or even, according to Deschales, ten thousand feet in horizontal extent; at most it must not be above one in six or seven thousand feet of declivity in equal spaces must slowly and gradually increase as far as the current is to be made fit for navigation; but in such a manner, that at this upper end there may not be above one foot of perpendicular declivity in four thousand feet of horizontal extent. If it is made greater than that in a regular bed containing a considerable volume of water, the current will be so strong as to be found very unfit for the purposes of navigation.

Mr. Massey calls the centre of the current, or more properly, line of greatest current, that line which passes through all the sections of a river, in the point where the velocity of the current is the greatest of all. If the current of a river is regular, and in a right line, its centre, or line of greatest velocity, will be precisely in the centre of the sections; but on the contrary, if the bed is irregular and full of turns and windings, the centre, or line of greatest current, will likewise be irregular, and will have its relation and direction with regard to the sections through which the waters flow, approaching successively, and more or less, to all parts of the bed, but always in proportion and harmoniously to the irregularities in the bed itself.

This division of the line of greatest current from the centres of the sections through which it passes, is a cause of many and great changes in the beds of rivers, such as the following:

1st. In a straight and regular bed, the greatest corrosion of the current will be in the middle of the bottom of the bed; because it is that part which is nearest to the line of greatest current, and at the same time which is most acted upon by the perpendicular direction of the water. In this case, whatever matters are carried off from the bottom will be thrown by the force of the current, equally toward the two sides, where the velocity of the stream is the least and slowest.

2dly. If the bed is irregular and winding, the line of greatest current will be thrown towards one side of the river, where its greatest force will be exerted in proportion to the local causes which turn it aside; in short, in a round stream there will be a gyration, or turning round of the stream, from its bearing against the outer side of the angle; this part will be corroded away, and the bottom near it excavated to a great depth. This matter, when cleared out, will be thrown against the opposite bank of the river where the current is the least, and produce a new ground called an alluvion.

3dly. Inequalities at the bottom of a river retain and diminish the velocity of the water, and sometimes may be so great as to make them reflow; all these effects contribute to the subsiding of sand, earth, and other matters, which cease not to augment the volume of the obstacles themselves, and produce shallows and banks in the channel. These in time, and by a continuance of the causes, may become islands, and so produce great and permanent changes and irregularities in the bed. The perfusion of the centre of the current against the sides of the bed are so much the greater as they are made under a greater angle of incidence; whence it follows, that the force of percussion will be the quantity of water excavated to the bottoms or sluices of rivers, and to the walls of buildings which are exposed to that percussion, are always in a direct compound proportion of the angle of incidence, of the greatness and depth of the section together, and of the quantity of velocity of the current.

4thly. It may happen in time, that the excavation of the bottom, and the corrosion of the sides, will have so changed the form of the river as to bring the force of percussion into equilibrium with the velocity and direction of the current; in that case, all further corrosion and excavation of the bed ceases.

5thly. This gives the reason why when one river falls into another almost in a perpendicular direction, and makes it too great an angle of incidence, this direction is changed in time, by corruptions and alluvions, into an angle much more acute, till the whole comes into a straight line.

6thly. So great and such continued irregularities, from local causes, may happen in the motion of a river as will entirely change its antient bed, corrode through the banks andislands, be the greatest violence of percussion of the stream, and open new beds in grounds lower than the old one is become.

7thly. Hereupon the state of the old bed will entirely depend on the quantity of water, and on the velocity and direction of the current in the new one; for immediately after this division of the waters into two beds is made, the velocity of the current in the old will be diminished in proportion to its less depth. In consequence, the waters will precipitate more of their mind, &c. in equal spaces than they did before; which will more and more raise up the bottom, sometimes even till it becomes equal with the surface of the stream. In this case, all the water of the river will pass into the new bed, and the old one will remain entirely dry. It is well known that this has happened to the Rhine near Leyden, and to many other rivers.

8thly. Hereupon the formation of the new branches and mouth, by which great rivers discharge their waters into the sea.
But in proportion as a river, that has none of these obstacles in its bed, approaches towards its mouth, we see the velocity of its current augment, at the same time that the deadness of the bank to the sea, is. At Ferrara, they are twenty feet high; whereas, nearer the sea, they do not exceed ten or twelve feet, although the channel of the river is not larger in the one place than in the other.

The mouths of rivers, by which they discharge their waters into the sea, are liable to great variations, which produce many changes in them.

1. The velocity and direction of the current at the mouths are in a continual variation caused by the tides, which alternately retard and accelerate the stream.

2dly. During the flowing of the tide, the current of the river is first stopped, then turned in the opposite direction, and entirely changed to a considerable extent: if we may believe M. de Buffon, there are rivers in which the effect of the tides is sensible at 150 or 200 leagues from the sea.

3dly. This state of things is a cause of a great quantity of sand, mud, &c. being precipitated and accumulated in the channel near the mouth. This continually raises and widens the bed, and at last changes it entirely into a new place, or at least opens new mouths to discharge the waters at the Rhine, the Danube, the Wolda, the Indus, the Ganges, the Nile, the Mississippi, and many other rivers, are instances of this.

4thly. All these effects are less sensible at the mouths of little rivers, as their currents oppose no sensible obstacle to the flowing of the tides; so that the ebb carries off again what the flow had brought in.

Whenever the course of a river throughout a considerable extent of country, approaches the coast, it will have a very great rapidity; and the velocity where-with it runs diminishing the effect of its natural gravitation, the middle of the current will rise up, and the surface of the river will form a convex curve of sufficient elevation to be perceived by the eye; the highest point of this curve is always directly above the line of greatest current in the stream.

On the contrary, when rivers approach near enough to their mouths for a sensible effect to be produced in them by the flowing of the tides; and also, when in other parts of their course they meet with obstacles at the sides of their channel; in both these cases the surface of the water at the sides of the current is higher than in the middle, even though the stream should be rapid. In this situation of things, the surface of the river forms a concave curve, the lowest point of which, or that point which lies on the line of greatest current. The reason of this is, that there are in this case two different and opposite currents in the river; that by which the waters flow towards the sea, and preserve their motion even to a considerable distance; and that of the waters which re-mount, either by the flowing of the tide, or by their meeting with local obstacles, which form a counter current.

An island in the mouth of a river produces the same effect as obstacles at the tides, regarding being had to the difference of situation of each.

Eddies and whirlpools in rivers, in the centre of which there appear conical or spiral cavities, and about which the water turns with great rapidity and sucks in whatever approaches it, proceed in general from the mutual percussion of these two counter currents; the movement being produced by the action of the centrifugal force, by which the water endeavours to recede, in a direct ratio of its velocity, from the centre about which it moves.

If rivers persevered always nearly in the same state, the best means of diminishing the velocity of the current when it is found too great for the purposes of navigation, would be by widening the channel; but as all rivers are subject to its quantity and increase and decrease, and consequently to very different degrees of velocity or current, this method is liable to produce very detrimental effects; for, when the waters are low, if the channel is very large in proportion, the stream will excavate a particular bed, and the water depth will be increased in this particular bed, and thereby will strike against the sides of the channel, so as to destroy the banks and cause great damages.

It would be possible to prevent in part the bad effects proceeding from the current striking against the banks, by opening, at those places where it strikes, little gulfs into the land, dug in such a form and direction as that the striking current should enter and circulate therein, so as to destroy, or at least, greatly diminish its velocity. This effect would be felt for a considerable way down the river.

This same method might probably be used with success against the destruction of bridges, weirs, &c. by the violence of the stream during floods, which being dug into the outer side of those turnings in the river which are immediately above the place to be secured from the violence of the stream, would successively diminish its velocity, its force and dangerous effects, a considerable way down the river.

RIVINA, a genus of the monogynia order, in the tridentaria class of plants. The perianthus is four-leafed, coloured, and permanent, the leaflet oblong and obtuse; there is no corolla, unless the calyx is conserved in the bud, or it may be of eight filaments, shorter than the calyx, approaching by pairs, permanent; the anthers are small. The pericarp is large and roundish; the style very short; the stigma simple and obtuse. The base of the calyx is green, the inside of the calyx is white.

The juice of the berries of the plant will stain paper and linen of a bright red colour, and many experiments made with it to colour flowers have succeeded extremely well. The juice of the berries was pressed out, and mixed with common water, putting it into a phial, shaking it well together for some time, till the water was thoroughly tinged; then the flowers, which were white when put in, were cut off, and their stalks placed into the phial; and in one night the flowers have been finely variegated with red; the flowers on which the experiment was made, were the tuberose and the double white narcissus.

RIX-DOLLAR, a silver coin current in different parts of Europe. See Coin.

ROACH. See CYPRINUS.

ROAD, in navigation, is a place of anchorage at some distance from shore, where vessels usually moor, to wait for a wind or tide proper to carry them into harbour, or to set sail. When the bottom is firm, clear of rocks and sheltered from the wind, it is called a good road; and if there is but little land on any side, it is termed an open road.

The roads in his majesty’s dominions are free to all merchant vessels, belonging to his subjects and allies. Captains and masters of ships who are forced by storms, &c. to cut their cables, and leave their anchors in the roads, are obliged to mark or buoys, on pain of forfeiting their anchors, &c. Masters of ships coming to moor in a good road anchor their vessels; and if it be a little land on any side, that is, so that the cables, &c. do not mix, on pain of answering the damages; and when there are several vessels in the same road, the outermost to the sea-ward is obliged to keep a light in his lantern in the night-time, to apprise vessels coming in from sea.

ROASTING. See METALLURGY.

ROB, in pharmacy, the juices of fruit purified and inspissated till it is of the consistence of honey.

ROBBERY, in law is a felonious taking away of another man’s goods from his person or presence against his will, putting him in fear and of force to steal the same. West. Symbol. To make a robbery there must be two persons, the person to be laid in the indictment. 1 H. 11. 532. It is immaterial of what value the thing taken is; a penny, as well as a pound thus forcibly exported, makes a robbery. 1 Haw. 34.

If a man forces another to part with his property, for the sake of preserving his character from the imputation of having been guilty of an unnatural crime, it will amount to a robbery, even though the party was under no apprehension of personal danger. Latch. Cor. Law. 257.

If any thing is snatched suddenly from the head, hand, or person of any one, without any struggle on the part of the owner, or without any evidence of force, or violence being exerted by the thief, it does not amount to robbery. But if any thing is broken or torn in consequence of the sudden seizure, it would be evidence of such force as would constitute it a robbery. A lady’s purse was torn by a diamond pin from her head, and an ear was torn by pulling off an ear-ring; each of these cases was determined to be a robbery. Latch. Cor. Law. 264.

By 7 C. H. c. 21, if any person shall, with
any offensive weapon assault, or by menaces, or in any fierce or violent manner, demand any money or goods, with no reasonable intent to rob; but generally, one should be guilty of felony, and be transported for seven years.

If any person being out of prison, shall commit any robbery, and afterwards discovers any two persons guilty of robbery, he shall have the king's pardon.

The hundred in which a robbery on the highway is committed, is liable to pay the damage when it is committed between the rising and setting of the sun, in any day, except Sunday, in case the robbers are not taken in forty days; and any being made after the fourth day, and any who apprehends and prosecutes a robber on the highway, so as to convict him, is entitled to receive of the sheriff of the county where the robbery was committed, the sum of forty pounds, with the help of the judge, and such person's producing a proper certificate from the judge before whom the robber was convicted.

ROBERGL, a genus of the class and order decandria pentagynia. The cal. is five-parted; pet. five; fr. four, the outer one or two, simple or valved. There is one species a shrub of Guiana. -

ROBINIA, false acacia, a genus of the decandria order, in the diadelphia class of plants; and in the natural method ranking under the 32d order, papilionaceae. The calyx is quadrate; the leguminous gibbs and elongated. There are seventeen species. The most remarkable is the caragana, the leaves of which are conglutinated, and composed of a number of small foliolates, of an oval figure, and banded leaves, that are in one common stock. The flowers are leguminous, and are clustered on a filament. Every flower consists of a small bell-shaped petal, cut into four segments at the edge, the upper part being rather the staminate. The seed is small, open, and rounded. The wings are large, oval, and a little raised. Within are ten stammas united at the base, curved towards the top, and rounded at the summit. The style is a slender stem, formed by the filaments of the stammas, the pistil is perceivable, consisting of an oval Gerran, terminated by a kind of button. This Gerran becomes afterwards an oblong flatish covered with pubescent, containing two or three seeds, of a large size and shape irregular and unequal; yet in both respects somewhat resembling a lentil.

This tree grows usually in the severe climates of Northern Asia, in a sandy soil mixed with black loam. It is particularly found on the banks of great rivers, as the Ob, Jenissi, &c. It is very rarely met with in the inhabited parts of the country, because cattle are very kind of its fruit, and by the height of its roots; and it is so hardy, that the severest winters do not affect it. Giraldus found it in the neighbourhood of Tobol's, buried under fifteen feet of snow and ice, yet laid it not suffered the least damage. Its culture exists in being planted or sowed in a sandy loamy soil, which must on no account have been lately manured. It thrives best near a river, or on the edge of a brook, or pond; but presently dies if planted in a marshy spot. If planted upon a rich soil, well tilled, it will grow to the height of twenty feet, and in a very few years will be as big as a common birch tree.

In a dry and soil this tree degenerates, and becomes a mere shrub: the leaves grow hard, and their fine bright green colour is changed to a dull deep green. The Tonga- nir Tartars, and the inhabitants of the northern parts of Siberia are very fond of the fruit of this tree, it being almost the only sort of pulse they eat. The leaves and tender shoots of this tree make excellent fodder for several sorts of cattle. The roots being sweet and succulent, are very well adapted for fattening hogs; and the fruit is greedily eaten by all sorts of poultry. After several experiments somewhat similar to the methods used with swine and indigo, a fine blue colour was procured from its leaves. The smaller kind of this tree seems still better adapted to answer this purpose. The striking elegance of its foliage, joined to the pleasing yellow colour of its beautiful flowers, should, one would imagine, bring it into request for forming handsome hedges. Besides the qualities above recited, it possesses the uncommon advantage of growing exceedingly quick, and of being easily transplanted. There are large plantations of it in Sweden, Norway, Lapland, and Iceland.

The robinia spinosa is a beautiful hardy shrub, and on account of its robust strong prickle, might be introduced into this country as a hedge plant, with much propriety. It resists the severest cold of the climate of St. Petersburg, and perfects its seed there. It rises to the height of six or eight feet; does not send out suckers from the root, nor ramble so much as to be kept with difficulty within bounds. Its flowers are yellow, and the general colour of the plant a light pleasing green.

ROBINSONIA, a genus of the icosophora monogynia class and order. The cal. is five-parted; pet. five; berry straited, two-celled; cells one-seeded; seeds villose. There is one species, a tree of Guiana.

ROCHFORTIA, a genus of the class and order pentandria digynia; the cal. is five-parted; cor. one-petalled, funnel-shaped; fruit two-celled, many-seeded. There are two species, of Jamaica.

ROCK-CRYSTAL. See Quartz.

ROCKET. See Pyrotechny.

ROCKS are divided into five classes: namely, 1. Primitive rocks; 2. Rocks of transition; 3. Stratified, or secondary rocks; 4. Alluvial deposits; 5. Volcanic rocks.

Rocks primitive.

The rocks belonging to this class are distinguished from all others in containing no remains of organic bodies, and being derived by the rocks of the other classes, but themselves covering any other class of rocks. The term primitive was applied by Lehaman, to whom we are indebted for the first scientific division of rocks, on the supposition that the rocks so denominated were formed before any other; and the term has been continued by Werner, because he has embraced the same hypothesis. The following table contains the different divisions of primitive rocks, arranged in the order in which Werner thinks they were formed.

1. Granite.
2. Gneiss.
4. Arglitaceous shisus.
5. Topazels.
6. Porphyr.
7. Serpentine.
8. Primitive limestone.

Let us take a view of each of these in order.

Granite is composed essentially of felspar, quartz, and mica, crystallized and united to each other. The size and proportion of the constituents vary exceedingly; but the felspar usually predominates, and the proportion of mica is smallest. Its texture is granular, and its hardness usually very considerable; hence it admits a fine polish, and is very beautiful and durable. Granite sometimes contains shorl accidentally mixed with it, and still more rarely garnets. Granite rocks are sometimes composition, and sometimes not.

They are very common, especially in great chains of mountains. Granite contains few ores. Those of iron and tin occur most frequently. See Granite and Gneiss.

Gneiss, like granite, is composed essentially of felspar, quartz, and mica; but they form plates which are laid on each other, and separated by thin layers of mica. The beds of gneiss sometimes alternate with layers of granular limestone, shisotse, hornblende, and porphyry.

Micaeous shisus. This rock is composed essentially of quartz and mica, which alternate in plates. The mica is usually most abundant. It is grey or brown, and sometimes greenish. The texture of micaeous shisus is essentially shisous. Its stratification is very distinct. It very frequently contains garnets, and sometimes felspar, cyanite, granite, and tourmalines. In mountains, beds of micaeous shisus often alternate with those of granular limestone and hornblende shisus, and are associated with those of actinize, pyrites, galena, and other metallic bodies. Indeed almost all the metals are found in it either in beds or veins.

Argilitaceous shisus. This rock is composed essentially of silex or silicious shisus; but it sometimes contains accidentally quartz, felspar, shil, hornblende, and pyrites. It is always shisous; but the thickness of these layers varies considerably. The beds of this rock are often interrupted by subordinate beds of other minerals; the chief of these are chlorite-shisus, talc-shisus, zeichen-schifer, clum-shisus. These frequently pass into argilitaceous shisus. Sometimes also beds of granular limestone, hornblende, and some metallic ores, alternate with argilitaceous shisus. This rock usually covers micaeous shisus.

Micaeous shisus are more common in this rock, but less so than in the two preceding. They are usually in veins.

Porphyry. The term porphyry is applied to all rocks consisting of a compact ground, in which distinct and separate crystals of some other substance are embedded. Werner confuses it to certain primitive rocks which belong to a particular formation. These, considered relative to their ground, are divided into five species, each of which is denominated from its ground.

1. Hornstone porphyry. The hornstone is sometimes conchoidal, sometimes splintery,
ROCKS.

599

and of a red or green colour. The crystals are quartz and felspar.

2. Felspar porphyry. The ground is usually red. The crystals are felspar and quartz.

3. Sienite porphyry. The ground is a mixture of felspar and hornblende. The crystals are felspar and quartz.

4. Pitchstone porphyry. The ground is red or green, sometimes brown, and even black.

5. Clay porphyry. The ground is an indurated clay, commonly red, which sometimes passes into jelly-like hornstone. The crystals are felspar and quartz; sometimes it contains hornblende, and more rarely mica.

Porphyry mountains are not stratified, and contain no beds of foreign substances. They are not rich in ores, yet frequently contain veins worth working.

Sienite. This rock is composed essentially of crystals of felspar and hornblende, immediately and intimately united. The felspar usually predominates. When the felspar is compact, the rock assumes a porphyritic structure. It sometimes contains accidentally grains of quartz and mica, but in a very small proportion. Its texture is granular, rarely stratified; it does not contain foreign beds. It sometimes contains metallic veins. It usually covers porphyry.

Serpentine. This rock is essentially simple. Sometimes it contains, accidentally, talc, asbestos, and statite; and sometimes mica, garnets, and granular limestone, magnetichornstone, arsenical pyrites, &c. Serpentine rocks are not stratified. Seldom contain beds of foreign minerals. They contain few ores, and seldom any worth working.

Primitæ limestone. This rock is essentially simple: its mass is granular limestone of a greyish white colour. Sometimes it is accidentally mixed with mica, quartz, hornblende, tremolite, actinote, asbestos, talc, &c. Its texture granular, the grains have a foliated texture, and a crystallized appearance. This rock sometimes contains metallic veins of pyrites, chalcedony, magnetichornstone, blonde, and pyrites.

Primitæ traps. The word trap is Swedish, and signifies a stair. It was applied by the Swedish mineralogists to certain rocks whose structure was similar to that of the jutting out under the other, gave an appearance somewhat like a stair. The term was adopted by other nations, and was applied indiscriminately to a great variety of rocks; which, yet bore a certain resemblance to each other. This generalization, however, introduced much confusion into the subject, which was first cleared up by Werner and his disciples. Under the term traps Werner comprehends certain series of rocks, distinguished chiefly by the hornblende, which they all contain. In the most antient, the hornblende is almost pure; this purity gradually diminishes, and in the most recent traps the hornblende-degenerates to a kind of interlaced clay stone. It is three formations of traps: 1. Primitæ traps; 2. Transition traps; 3. Secondary traps. The first only occupy our attention at present.

The primitive traps are composed almost entirely of felspar, which is sometimes mixed with felspar, more rarely with mica and pyrite. There are four species: 1. Common

ground are two species of rocks of grauwacke, common and shistose.

Grauwacke. There are two species of rocks of grauwacke, common and shistose.

Common grauwacke is a siltstone composed of grains of quartz, kieschieder, and argillaceous shistus, agglomerated by a cement of clay. The grains are sometimes very small, sometimes as large as a hazel nut.

Grauwacke are traversed by veins of quartz. They contain sometimes shells and reeds petrified. They contain no foreign beds. These rocks are distinctly stratified. The strata do not run parallel to those of the other rocks on which they lie. They usually cover transition limestone, and do not rise to any great height. They are rich in ores.

Transition traps. The principal base of all the rocks belonging to this formation is grauwacke. This constitutes many of the primitive traps; but in the transition traps, the mixture is much more intense, the grain is much finer, and the mass much more homogeneous, and its constituents are more or less blended together. Transition traps consist principally of two species, mandelstein and globular trap.

1. Mandelstein or argilloglaucon. By this term is implied all rocks composed of a compact ground, containing interbedded in it minerals of a round or almond form, or containing cavities of that form. They are distinguished into primitive, transition, and secondary mandelsteins. Transition mandelstein consists of a ground of shistose hornblende, decomposed and resembling wacken or foruginous clay. The cavities are sometimes empty, sometimes full, and then they contain quartz and clodeline. This stone of Derbyshire is referred to this species. It contains round masses of calcareous spar.

2. Globular trap. This is a shistose grunstein, partly decomposed and reduced to the state of a fine grained wacken. It is composed of large spherical bodies, consisting of concentric layers; the central part being hardest.

Transition traps are not stratified. They form separate conical mountains, usually near those of transition limestone. They contain some metallic veins of copper, iron, tin, &c.

CLASS III.

Rocks secondary.

These rocks are distinguished by the resemblance of organs of the original rocks, which they contain abundantly. They are usually stratified. The following table contains a list of these different rocks, arranged according to the supposed time of their formation.

1. Sandstone, 6. Pit coal,
2. Gritstone, 7. Eiselstein,

Sandstone. This rock is composed of quartz, varying in size; sometimes also grains of kieschieder, and very splintery of felspar. These grains are cemented together, sometimes by means of clay, sometimes of mud or lime, and sometimes of quartz. The cement varies in quantity, but never predomin-
The size of the grains varies much; when large, the rock is usually called pudding stone.

2. This rock is very distinctly stratified. The beds of it often alternate with beds of compact limestone, red clay, slate, and a species of sandstone, which is fine-grained, and mixed with laves of mica, which gives it the appearance of micaceous shist. It contains two metallic ores of value. Sometimes coal is found in it.

Secondary limestone. This rock is simple, and composed of compact limestone. Occasionally it contains crystals of quartz, pyrite, etc. Shells occur very frequently in it. It is very distinctly stratified. Its beds are sometimes separated by beds of shistose bituminous marl and sandstone, and by terraces of hornstone and flat often arranged in beds. It is often traversed by metallic veins, chiefly of galena, grey copper ore, malachite, etc.

Chalk. The strata of chalk may be considered perhaps as analogous to those of secondary limestone. They consist entirely of limestone and are traversed by thin beds of flint in terraces. Shells often occur converted into silicious matter, and sometimes pyrites in spherical masses. No metallic ores ever occur in them.

Gypsum. The strata of gypseum usually occur in mountains alternating with those of sandstone, limestone, marl, clay, rock salt. They often contain foreign crystals, chiefly quartz, aragonite, horsetail, garnet; sometimes they contain sulphur. Few petrofacies are found in them except the bones of quadrupeds. They contain scarcely any metallic ores. See Sulphate of Lime.

Rock salt. The mountains which contain strata of rock salt are to be referred to a particular formation of gypseum, with which they usually alternate. They contain no ores.

Pit coal is found in two different formations. The first of these is distinguished particularly by the name of coal formation, or mountains of coal. They are usually composed of beds of: 1. Very brittle sandstone, containing often small particles of mica; 2. Limestone of very large grains; 3. Shistose clay; 4. Marl; 5. Limestone; 6. An argillaceous porphyry distinguished by the name of secondary porphyry; 7. Ferruginous clay; 8. Coal. The beds of coal vary in thickness, and in number.

This formation of coal occupies countries of no great elevation. They occur chiefly at the bottom of chains, and in the intermediate valleys. The strata of coal in the north of England belong to it.

Coal is found in other situations, especially in the secondary trap formation. Those of Scotland belong to this class.

Argillaceous lavas. The beds of this mineral usually alternate with those of indurated clay, shistose clay, marl, brachiopods, and sandstone. They frequently contain calamine mixed with galena. The impressions of plants and marine petrofacies are often observable in them. They usually form small insulated lumps, and are not very common.

Secondary traps. The mountains of secondary traps are composed of various rocks; some of which belong exclusively to this formation; others are found also in other mountains. The rocks peculiar to secondary traps are: 1. Basalt; 2. Wacken; 3. Basaltic tuff; 4. Secondary mudstone; 5. Porphyry shistus; 6. Graustein; and, 7. Secondary graustein.

1. Basalt, considered as the mass of a mountain, is a rock more or less composed of a glassy, or glassy, and obsidional, structure, and for its ground the mineral called basalt. It contains usually grains of olivine, augite, basaltic hornblende, magnetic ironstone, and sometimes kaolite, felspar, quartz, &c.; sometimes also mica, actinolite, clinohumite. Sometimes we observe the ironstone is so detritus that in case its cavities are filled with zeolite, steatites, limestone, &c.

It usually appears in large separate masses often prismatic. It is very common often forming detached mountains.

2. Wacken sometimes forms beds in the secondary traps. It is usually between clay and basalt. It neither contains olivine nor augite, but crystals of basaltic hornblende, and about 10 per cent of felspar. The last substance distinguishes wacken from basalt, which very seldom contains it.

3. Basaltic tuff results from the decomposi- tion of certain basalt. It consists of fragments of this rock, and contains the remains of vegetables, &c., agglutinated by a cement of clay.

4. The amygdaloids or medullates of the secondary traps have for their base a clay-andalusite, and decomposed granite, often penetrated with silicious matter. It has a good deal of resemblance to wacken, and sometimes passes into it; at other times it assumes a more compact texture, and passes into basalt. Its cavities are sometimes empty, sometimes filled with green earth, zeo- lite, limestone, &c.

5. Porphyry, sithistus is a rock whose structure is shistose, and its texture porphyritic. Its base is kaolinite, containing grains of felspar, and sometimes of hornblende. It has a good deal of resemblance to basalt, and often passes into it. But it is more nearly a chemical compound, being more transparent, sonorous, and hard.

6. Graustein is a rock composed of small grains of felspar and hornblende, which graduate into each other and form a mass almost homogeneous of an ash grey colour. It contains olivine and augite.

7. Secondary graustein, like the primitive and transition, is composed of hornblende and felspar; but its grains are less perfectly crystallised, and less intimately mixed. It usually covers rocks of basalt.

Such are the rocks peculiar to thesecondary
trap formation. They have all less or more of a crystallised structure; whereas the other minerals found in secondary traps, but not peculiar to them, are mechanical depositions. Wacken and basalt form the passage from the one to the other. The mechanical depo-
sitions, sand, clay, &c., are usually lowermost; they are covered by wacken. Some of the other substances always occupy the summits. These consist of a considerable abundance of petrofacies, but no ores except some veins and grains of iron. They are usually insulated; very seldom forming chains. Some of the other substances always occupy the summits.

Traps. Some of the trap formations present a greater abundance of petrofacies, but no ores except some veins and grains of iron. They are usually insulated; very seldom forming chains. The mountains of basalt and porphyry shistus are usually covered by rocks. They are hardly ever covered by other rocks. They usually cover sandstone, coal, secondary limestone, shistose clay; and veins of them are not uncommon in primitive mountains.

Class V.

Rocks volcanic.

This name is given to all the minerals thrown out during volcanic eruptions. The most complete account of them has been given by Dolomieu, who devoted the greatest part of his life to the study of volcanoes. Part of his division was published by him in the Journal de Physique for 1794; and an account of the whole has been given by Brochard from notes taken during a course of geology given by Dolomieu in 1797. Volcanic products have been divided by this celebrated geologist into five classes: 1. Minerals modified by the fire of volcanoes; 2. Substances not modified by the fire, but thrown out unaltered; 3. Substances subjected by the fire of volcanoes; 4. Minerals altered by the sulphurous acid vapours of volcanoes; 5. Volcanic minerals, affected by the action of the atmosphere.

Minerals modified by the fire. This set of minerals is subdivided into two heads. The first comprehends those minerals which, though they have been modified by fire, yet exist in no other combination. The second consists of those which retain obvious marks of the action of fire. Those of the first head have been distinguished by the name of compact lavas; those of the second by the name of porphyry.

Compact lavas bear so close a resemblance to certain rocks of an origin not volcanic, that it is extremely difficult to distinguish them. Some have the appearance of basalt; others of granite, porphyry, and various secondary traps. Dolomieu divides them into four species according to their base.

1. Compact lavas with an argillaceous

core. Their colour is usually black. Fracture imperfectly conchoidal. Texture very compact. Sonorous. Shell argillaceous. Attract the magnetic needle. Very common in volcanic countries. Frequently contains crystals of augite, felspar, hornblende, garnet, leucite, olivine, mica. A specimen of the lava of Catania in Sicily, analysed by Dr. Kennedy, contained:

97.5.

Compact lavas with a petrosilicaceous base. Colour very variable, grey, black, and white; but all become white before the blow-pipe. Fracture conchoidal. Grain fine and compact. Shells slightly argillaceous. Does not affect the magnetic needle. Contains unifiny
Nearly the same result had been previously obtained by Dr. Kennedy.

Volcanic sands and ashes. The sands are composed of grains varying in size. They are usually mixed with crystals of felspar, such as orthoclase, microcline, &c. and often cover a great extent of ground. Vesuvius has covered the country for 50 leagues round it with a bed of sand twelve feet thick. Volcanic ashes are merely very fine sand. They are so light that during the eruptions of Etna, the winds often transport them as far as Egypt.

Agglutinated matters. These are merely sands and ashes covered and cemented together by a torrent of molten lava.

Calced substances. All stony bodies which have undergone a kind of calcination by volcanic fires are denoted by this name. All volcanic matters often undergo this change. Their grain is rendered more harsh, and their feel more dry. The fergusious lavas become more red, and cease to be attracted by the magnet.

Minerals not modified by the fire. These remain as they were in the mountain before the commencement of volcano action, and are thrown out by it unaltered. The study of them is important, because they inform us of the internal structure of volcanic mountains.

They generally belong to the primitive rocks. Sometimes they are fragments of rocks, and sometimes groups of crystals. They are thrown out in general at the beginning of eruptions.

Volcanic ashes sometimes emit torrents of muddy water. From these have originated the minerals called volcanic tufas. Their colour is various.

Substances sublimed. An immense quantity of matter is exhaled by volcanoes; partly in the state of gas or steam, partly in a visible form.

Hydrogen gas, carbonic acid, sulphurous acid, muriatic acid, nitric acid, &c. have been detected issuing from them.

The mineral substances which are sublimed from them, and which afterwards are deposited on their sides, are sulphur, which is very abundant; mineral oil, and various salts, especially nitrates of ammonia, soda, copper, and iron; sulphate of iron; and carbon of soda. Metallic bodies are also found among these substances: iron, copper, antimony, arsenic, cinnabar, &c.

Substances altered by sulphurous acid vapours. The sulphur volatile by volcanics is often converted into an acid, which, acting upon the lavas, changes their appearance considerably. They become of a yellowish-white colour, much lighter and dryer, and are more easily pulverized. They contain an unusual proportion of silica, because the sulphurous acid has combined with the alumina, and formed a salt afterwards washed away by the rain. The same vapours often attack stony matters not volcanic.

The principal products of the action of these vapours on lavas are alum and sulphas of lime, magnesium, and iron. These salts, especially the first, are collected with great advantage.

Volcanic substances altered by the action of the atmosphere. All rocks undergo greater or smaller changes when long exposed to the atmosphere, but these changes are much greater and more rapid in volcanic rocks than in others. Sometimes, however, they are very slow. Hence the age of volcanoes cannot be determined by the state of their volcanic eruptions.

The argilo-ferruginous lavas become first petrified; the petrified strata become of a dirty grey. By degrees they assume an earthy appearance, and pass at last to a kind of friable clay. The scoria undergo the same changes much more rapidly. The earthy matters produced by this decomposition are afterwards washed down by the waters, and form large beds, which constitute a very fertile soil. The porous lavas are often partly filled with earth washed down by rains from decomposed lavas. Dolomieu supposed many crystals to owe their existence to the inclusions of such waters.

Besides the real products of volcanoes, there are rocks which have been more or less altered by the action of fires not volcanic. These fires have often originated in the combustion of strata of coal. These have been called pseudo-volcanic rocks. These rocks are four in number; namely, porcelain jasper, brown, earthy scoria, and a particular variety of polierischei.

Porcelain jasper is considered as a stiostoic clay, which has been calcined. Burnt clay resembles brick: it has been exposed to a lesser fire than porcelain jasper. Like that mineral it is considered as having been originally a stiostoic clay. Earthy scoria are light porous substances like scoria. They appear to have been melted. They are usually near the strata. A variety of polierischei sometimes occurs, which apparently have been to a clay exposed to a moderate degree of heat, and rather dried than calcined. To these pseudo-volcanic minerals may be added the vitrified sorts, not uncommon in the highlands of Scotland. They seem to have originated from artificial fires. See GEOLOGY, MOUNTAINS, MINERALOGY, &c.

ROD, a land measure of sixteen feet and a half: the same with perche and pole. 

ROE, in gauging. See GAUGING.

ROE, the spawn or seed of fish. That of male fishes is usually distinguished by the name of milt, or milt, and that of the female, by hard-milt, or spawn.

So inconceivably numerous are these ovula, or small eggs, that Mr. Petit found 342,144 of them in a carp of eighteen inches; but Mr. Leenebenock found in a carp no more than 211,069. This last gentleman observes, that there are four times this number in a cod, and that a common one contains 9,344,000 eggs.

ROella, a genus of the monogynia order, in the pteridaria class of plants; and in the natural method ranking under the twenty-ninth order, campagnaera. The corolla is funnel-shaped, with its bottom shut up by staminal infundibulae; the stigma is bi-lobed, the capsule bilocular, and cylindrical inferior. There are five species, shrubby plants of the Cape.

ROGUE, in law. See VAGRANT.

RHIORA, a genus of the class and order triamium monogynia: the eal is bell-shaped, five-petalled, unisexual; stigma simple, revolute: caps. There is one species, a shrub of Guiana.

ROLANDRA, a genus of the class and order synergasia polygama superbia. The
fleorses are banded in a head with scales interspersed; called two-celled, one-sowered, and single-ecorys hermaphrodite. There is one species, a shrub of the West Indies.

ROLL, in manufactories, something wound and folded up in a cylindrical form.

Frame rolls, represented by the genus feet, exist as sallies, gauges, and creases, which are apt to break, and take plats not easy to be got out, if folded otherwise. Ribbons, laces, galloons, and pads of all kinds, are also thus rolled.

A roll of tobacco is tobacco in the leaf, twisted on the mull, and wound twist over twist, about a stick or roller. A great deal of tobacco is sold in America in rolls of various weights; and it is not till its arrival in England, Spain, France, and Holland, that it is cut. A roll of parchement properly denotes the quantity of sixty skins.

Theautists made all their books up in the form of rolls, and in Cicero's time the library consisted wholly of such rolls.

Roll, in law, signifies a schedule or parchement which may be rolled up by the hand into the form of a pipe.

In these schedules of parchement all the pleading, memorials, and acts of court, are entered and filed by the proper officer; which being done, they become records of the court. Of these there are in the exchequer several kinds, as the great workhouse-roll, the cointry-roll, the subsidy-roll, &c.

Roll is also used for a list of the names of persons of the same condition, or of those who have entered into the same engagement. Thus a court-roll of a mayor, bailiff, or in which cases, and services of each tenant are copied and enrolled.

Roll, master, that in which are entered the soldiers of every troop, company, regiment, &c. As soon as a soldier's name is written down on the roll, it is death for him to desert.

Rolls-office, is an office in Chancery-lane, London, appointed for the custody of the rolls and records in chancery. Rolls of parliament, are the manuscript registers, or rolls of the proceedings of our antient parliaments, which before the invention of printing, were all engrossed on parchement, and preserved properly in every country; in which rolls are also contained a great many decisions of different points of law, which were frequently in former times referred to the decision of that high court.

Roll, or Roller, is also a piece of wood, iron, brass, &c., of a cylindrical form, used in the construction of several machines, and in several works and manufactories.

A rolling-mill shewn in fig. 4. Plate, consists of two iron rollers A B, mounted in a strong iron frame, which consists of two distinct parts D E, both firmly fixed to the iron floor F; each has a long mortise through it, in the bottom of which is the brass socket for the pivot of the roller A; and in the upper part is the brass of the upper roller; this last brass is fixed to a piece of iron G, fig. 5, which slides up and down in the mortise, and is prevented from raising at the end of a stroke, by a screw a, screwed through the brass of the end of the frame D; the roller is prevented from falling by its own weight, by the brass b in the under side of the pivot, which is attached by two screw-bolts d to a collar upon the screw a, so that when the screws are turned by a hand-spike put between the teeth of the wheel H, the rollers A and B may be brought nearer together or farther off, as occasion requires. It is a stout iron bar, fixed between the frames D E by a wedge i at each end. The face is level with the top of the lower roller; at a small distance above this, is another bar k, fixed by two screws, between these are laid several blocks of iron L, so as to fill up all the space, except the opening, through which the bar to be flattened is introduced; thus is a small trough of iron plate, bored full of holes, to which fluid water is brought by a small pipe p. The upper roller is put in motion by a strong shaft H, which conveys the power from a water-wheel, &c.; and the lower one is moved by a cog-wheel S, on the shaft R, which turns another T, on the axis of the lower roller. The machine is placed near to a furance, where the iron bars are to be rolled, are heated to a welding heat; the mill is then put in motion, and the iron bars taken out, with a pair of pinches, and their ends put through the opening between the bars k and L, before the roller s, which then square and squeeze the iron flat, and to the proper thickness throughout, while other men behind the machine, convey it away. The rollers can be set nearer or farther off by turning the pair of keys described. The plough-mouth is principally used for making hoops for barrels, and iron plates; the water brought by the pipe p is to prevent the roller from being heated by the iron.

ROLLER, in surgery, a long and broad handle, usually of linen-clot, rolled round any part of the body, to keep it in, or dispose it to a state of health.

RONDELETTA, a genus of the monogynia order, in the penicillin class of plants, and in the natural method ranking with those of which the order is doubtful. The corolla is funnel-shaped; the capsule bilocular, inferior, and polyporous, rounded, and crowned. There are 14 species, shrubs of the West Indies.

ROOD, a quantity of land equal to forty square perches, or the fourth part of an acre.

ROOF. See Architecture.

ROOK, in ornithology. See Corvus.

Root, in mathematics, a quantity considered at the basis or foundation of a higher power; or which being multiplied into itself any number of times, produces a square, cubic, &c., quadratic, &c., quantity; called the second, third, fourth, &c., power of the root, or quantity, so multiplied into itself; thus a is the square root of a x a, or + a, and 4 the square root of 16 a a = a 2 ; again, a is the cube-root of a x a x a = a 3 ; and 3 the cube-root of 3 x 3 x 3 = 27 ; and so on. See Algebra.

The roots of equations are expressed by placing the radical sign + over them, with a number denoting what kind of root they are: thus the square or second root of 16 is expressed by + 16; the cube or third root of 27 by + 27; and, in general, the nth root of a raised to the mth power, is expressed by a m/n. When the root of a compound quantity is wanted, the vinculum of the radical sign must be drawn over the whole; thus the square root of a 2 + b 2 is expressed by a 2 + b 2 ; and it ought to be understood, that when the radical sign has no number above it, to denote what root is wanted, the square root is always meant; as + a, or + a 2 , is the square root of a, or the square root of 16. ROPE, hemp, hair, &c., spun into a thick yarn, and then several strings of this yarn twisted together in the same manner as a single rope. When it is laid up on a board it is called a cord, and when very thick, a cable. All the different kinds of this manufacture, from a fishing-line or whipcord to the cable of a first-rate ship of war, go by the general name of cordage.

Cordage is made of every substance that is sufficiently fibrous, flexible, and tenacious, and chiefly of the inner barks of plants. The Chinese and other orientals even make them of the ligneous parts of several plants, such as certain hemp, and reeds, the stems of the aloes, the fibrous covering of the coconuts, the filaments of the cotton-pot, and the leaves of some grasses, such as the sparte (lygern, Limn.). The aloe (agave, Limn.) and the aloes is exceed all others in strength. But the barks of plants are the most productive of fibrous matter fit for this manufacture. Those of the linden tree (tilia) of the willow, the bramble, the meadowsweet, are frequently used; but of all these the hemp is preferred, and employed in all cordage exceeding the size of a line, and even in many of this denomination.

Hemp is very various in its useful qualities; the hemp in Europe comes to us tho' gh Riga, to which port it is brought from very distant places southward. It is known by the name of rigma relis (that is, clean hemp). Its fibre is not the longest (for the dressed state of it, get it) but it is the finest, most flexible, and strongest. The next to this is supposed to be the Petersburgh break hemp. Other hampers are esteemed nearly in the following order: Petersburgh-out, hemp from Köningsburg, Archangel, Sweden, Memel. Chucking is a name given to a hemp that comes from various places, long in the fibre, but coarse and hard, and its strength is inferior to hemp which appears weaker. Its texture is such, that it does not admit splitting with the hatchet, so as to be more completely dressed; it is, therefore, kept in its coarse form, and used for inferior cordage. It is, in length and strong hemp, but will not make fine work. There are doubtless many good hamps in the southern parts of Europe; but little of them is brought to our market. Cordage, half clean, &c. are portions of the above-mentioned hamps, separated by the dressing, and may be considered as broken fibres of those hamps.

Only the first qualities are manufactured for the rigging of the royal navy, and for the ships of the East India company.

ROPE-MAKING, is an art of very great importance; and there are few that better deserve the attention of the intelligent observer. Hardly any art can be carried on without the assistance of the rope-maker. Cordage makes the very sinews and muscles of a ship, and every improvement which can be made in its preparation, either in respect to strength, beauty, or durability, must be of great importance to the mariner, and to the commerce and the defence of nations.

The aim of the rope-maker is to unite the strength of a great number of fibres. This would be done in the completed manner by
ROPE-MAKING.

Laying the fibres parallel to each other, and fastening the bundle at the two ends; but this would be of very limited use, because the fibres are short, not exceeding three feet and a half at the most, and must therefore be entangled together, in such a manner that the strength of a fibre shall not be able to draw it out from among the rest of the bundle. This is done by twisting or turning them together, which causes them mutually to compress each other. When the fibres are so disposed in a long skain, that their ends extend each other along its length, without any of them meeting in one place; and this skain is twisted round, we may cause them to compress each other to any degree we please; and the friction on a fibre which we attempt to pull out, may be more than its cohesion can overcome. It will therefore break. Consequently, if we pull at this twisted skain, we shall not separate it by drawing one parcel out from among the rest, but the whole fibres will break; and if the distribution of the fibres has been very equal, the skain will acquire the same strength in every part. If there is a large bundle, where many ends of fibres meet, the skain will break in that part.

We know very well that we can twist a skain of fibres so very hard, that it will break with great attempt to twist it further. In this state all the fibres are already strained to the utmost of their strength. Such a skain of fibres can have no strength. It cannot carry a weight, because each fibre is already strained in the same manner as if loaded with as much weight before it as bear. What we have said of this extreme case is true in a certain extent of every degree of twist that we give the fibres. Whatever force is actually exerted by a twisted fibre, in order that it may sufficiently compress the rest to hinder them from being drawn out, must be considered as a weight hanging on that fibre, and must be deducted from its absolute strength of coherence, before we can estimate the strength of the skain. The absolute strength of a skain is the remainder of the absolute strength of the fibre, after we have deducted the force employed in twisting them together. From this observation we find one fundamental principle in rope-making, that twisting, beyond what is necessary for preventing the fibre from being drawn out without breaking, diminishes the strength of the cordage, and should be avoided when in our power.

It is necessary then to twist the fibres of hemp together, in order to make a rope; but we should make a very bad rope if we contended ourselves with twisting together a bunch of hemp fibres before we endeavors to withstand the strain to which the rope is to be exposed. As soon as we let it go out of our hands, it would untwist itself, and be again a loose bundle of hemp; for the fibres are strained, and they are so made as to twist downwards or vice elastic, they contract again, and thus untwist the rope or skain. It is necessary to confine the twist in such a manner, that the tendency to untwist in one part may act against the same tendency in another, and balance it. The process, therefore, of rope-making becomes more complicated.

The first part of this process is spinning of rope-yarns, that is, twisting the hemp in the first instance. This is done in various ways, and with different machinery, according to the nature of the intended cordage. We shall confine our description to the manufacture of the larger kinds, such as are used for the stringing and running rigging of ship.

An alley or walk is inclosed for the purpose, about 200 fathoms long, and of a breadth suited to the extent of the manufacture. It is sometimes covered above. At the upper end of the rope-walk is set up the spinning-wheel, of a form resembling that in Plate Misc. fig. 210. The band of this wheel goes over several rollers called whirns, turning on pivots in brass holes. The pivots at one end come in and out of the frame, and terminate in little hooks. The wheel being turned by a winch, gives motion in one direction to all those whirns. The spinner has a bundle of dressed hemp round his waist, with the two ends fastened. The hemp is laid in this bundle in the same way that women spread the flax on the distaff. There is great variety in this; but the general aim is to lay the fibres in such a manner, that as long as the bundle lasts there may be an equal number of the ends at the extremity, and that a fibre may never offer itself double or in a sight. The spinner draws out a proper number of fibres, twists them with his fingers, and so sets them in the greatest degree of order, that he fixes it to the hook of a whirn. The wheel is now turned, and the skain is twisted, becoming what is called a rope-yarn, and the rope-walks backwards down the rope-walk. The parcel of yarns, as far as it is necessary, are twisted with it more fibres out of the bundle. The spinner spins this with his fingers, supplying hemp in the proportion as he walks away from the wheel, and to the care that the fibres came in equally from both sides of his bundle, and that they enter always with their ends, and not by the middle, which would double them. He should also endeavour to enter them at the heart of the yarn. This will cause all the yarn to wind regularly in making it up, and will make the work smooth, because one end of each fibres is by this means buried among the rest, and the other end lies outward; and this, in passing through the greave barbar and the press, it tight with his thumb and palm, is also made to lie smooth. The greatest fault that can be committed in spinning is to allow a small thread to be twisted off from one side of the hemp, and then to cover this with hemp supplied from the other side; for it is evident, that the fibres of the central thread make very long spirals, and the skin of fibres which cover them must be much more oblique. This covering has but little cohesion with what is below it, and will easily detach itself. But even while it remains, the yarn cannot be strong, for on pulling it, the middle part, which lies the weight, must bear all the strain, while the outer fibres that are lying obliquely, are only drawn a little more parallel to the axis. This defect will always happen if the hemp is supplied in a considerable number of bundles, and if it is then used up whole. As soon as it is made to enter, it becomes a sort of loosely connected wrapper. Such a yarn, when untwisted a little, will have the appearance of a flax, while a good yarn looks like fig. 212. A good spinner therefore, endeavors always to supply the hemp in the form of a thin flat

skain with his left hand, while his right is employed in grasping firmly the yarn that is twisting off, and in holding it right from the whirn, that it may not run into loops or kinks.

It is evident, that both the arrangement of the fibres and the degree of twisting depend on the skill and dexterity of the spinner, and that he must be instructed, not by a book, but by a master. The degree of twist depends on the rate of the wheel's motion, combined with the retrograde walk of the spinner.

We may suppose him arrived at the lower end of the walk, or that far as is usual, for the intended length of his yarn. He calls out, and another spinner immediately detaches the yarn from the hook of the wheel, gives it to another, who carries it aside to the reel, and the second time that 19 of his own hemp out of the wheel-hook. In the mean time, the first spinner keeps fast hold of the end of his yarn; for the hemp, being dry, is very elastic, and if he were to let it go out of his hand, it would instantly unmelt, and would be much better than loose hemp. He waits, therefore, till he seers the reeler begin to turn the reel, and he goes slowly up the wheel, keeping the yarn of an equal tightness all the way, till he arrives at the wheel, where he waits, and this hemp in his hand till another spinner has finished his yarn. The first spinner takes it off the wheel-hook, joins it to his own, that it may follow it on the reel, and begins a new yarn.

Rope-yarns, for the greatest part of the large rigging, are from a quarter of an inch to somewhat more than a third of an inch in circumference, or as a size that 100 fathoms weigh from 34 to 4 pounds when wet. The different sizes of yarns are named from the number of them contained in a strand of a rope of three inches in circumference. Few are so coarse that 19 may make a strand of British cordage: 18 is not infrequent for cable yarns, or yarn spun from harsh and coarse hemp; 25 is, we believe, the finest size which is worked up for the rigging of a ship. Much finer is spun for sounding-lines, fishing-lines, and nainbow and gunny uses, and for other demands of society. Ten good spinners will work up above 600 weight of hemp in a day; but this depends on the weather. If the hemp be dry, the hemp is very elastic, and requires more attention to make smooth work. In the warmer climates the spinner is permitted to moisten the rag with which he grasps the yarn in his eight hand for each of his own hemp out of the wheel-hook. No work can be done in an open spinningmill in rainy weather, because the yarns would not take on the rag, if immediately turned, and would rot if kept on the reel for a long time.

The second part of the process is the conversion of the yarns into rope, which may be properly called a rope, cord, or line. At this we may have a clear conception of the principle which regulates this part of the process, we shall begin with the simplest possible case, the use of two yarns into one line. This is not a very usual fabric for rigging, but we select it for its simplicity.

When hemp has been split into very fine fibres by the hatchet, it becomes exceedingly soft and plant, and after it has him for some time in the form of fine yarn, it may be unraveled and drawn by force, without losing much
of its twist. Two such yarns may be put on the wheel of a spinning-wheel, and thrown, like flaxen yarn, so as to make sewing thread. It is in this way, indeed, that the sailmakers’ sewing thread is manufactured; and when it has been kept on the reel, or on balls or bobbins, for some time, it acquires its twist, as well as its uses require. But this is by no means the case with yarns spun for great cordage. The hemp is so elastic, the number of fibres twisted together is so great, and the diameter of the yarn, which is a yard of linen which remains, the elasticity of the fibre exerts itself) is so considerable, that no keeping will make the fibres retain this constrained position. The end of a rope-yarn being thrown loose, it will immediately untwist, and this with considerable force and speed. It would, therefore, be a fruitless attempt to twist two such yarns together; yet the ingenuity of man has contrived to make use of this very tendency to untwist not only to counteract itself, but even to produce another and a permanent twist, which requires force to undo it, and which will recover itself when this force is removed. Every person must recollect, that when the spinners turn the spool to their thread, and his fingers between his two hands, if he slackens the thread by bringing his hands nearer together, the thread will immediately curl up, running into loops or knots, and will even twist itself into a neat and firm cord.

The component parts of a rope are called strands, and the operation of uniting them with a permanent twist is called laying or cleaving. The latter term is slightly more applied to cables and other very large cordage.

Lines and cordage less than 14 inches circumference are laid at the spinning-wheel. The workman fastens the ends of each of two or three yarns to separate whirl-hoops. The remote ends are united in a knot. This is put on one of the hooks of a swivel called the loper, represented in fig. 213, and care is taken that the care of each end is by length and twist. A piece of soft cord is put on the other hook of the loper; and, being over a pulley several feet from the ground, a weight is hung on it, which stretches the yarn. The workman sees that they are equally stretched, he orders the wheel to be turned in the same direction as when twining the yarns. This would twine them harder; but the swivel of the rope gives way to the strain, and the yarns immediately twist around each other, and form a line or cord. In doing this, the yarns lose their twist. This is restored by the wheel. But this simple operation would make a very bad line, which would be slack, and not hold its twist; for, by the turning of the loper, the strands twist immediately together, to a great distance from the loper. By this turning of the loper the yarns are untwisted. The wheel restores their twist only to that part of the yarns that remains separate from the others, but cannot do it in that part where they are already turned round each other, because their mutual pressure prevents the twist from advancing. This is overcome, necessary to retard this tendency to twine, by keeping the yarn apart. This is done by a little tool called the top, represented in fig. 314.

It is a truncated cone, having three or more notches along its sides, and a handle called the staff. This is put between the strands, the small end next the loper, and it is pressed gently into the angle formed by the yarns which lie in the notches. The wheel being now turned, the yarns are more twisted, or hardened up, and their pressure on the twist gives it a strong tendency to come out of the angle, and also to turn round. The workman does not allow this till he thinks the yarns sufficiently hardened. Then he yields to the pressure, and the top comes away from the swivel, which immediately turns round, and the line begins to lay. Gradually yielding to this pressure, the workman slowly comes up towards the wheel, and the laying goes on, till the top is at last close to the wheel, and the work is done. In the mean time, the yarns are shortened, both by the twining of each and the laying of the cord. The weight, therefore, gradually rises. The use of this weight is evidently to oblige the yarn to take a proper degree of twist, and not run into kinks.

A cord, or line, made in this way, has all some tendency to twist a little more. However little friction there may be in the loper, the twist into which the cord has made in the laying, are not enough to balance completely the elasticity of the yarns; and the weight being appended, causes the strands to be more nearly in the same number, in the same manner as it would stretch and untwist a little any rope to which it is hung. On the whole, however, the twist of a laid line is permanent, and not like that upon twist doubled or thrown in a thread; which remains only in consequence of the great softness and flexibility of the yarn.

The process for laying or closing large cordage is considerably different from this. The strands of which the rope is composed consist of many yarns, and require a considerable degree of hardening. This cannot be done by a whirl driven by a wheel-land; it requires a strong, or a crank turned by the man. The strands, when properly hardened, become very stiff, and when bent round the top, are not able to transmit force enough for laying the heavy and unpliant rope which forms beyond the top. The strands must, therefore, be assisted by an external force. All this requires a different machinery and a different process.

At the upper end of the walk is fixed up the tackle-board, fig. 215. This consists of a strong oaken plank called a breast-board, having three or more holes in it, as A, B, C, fitted with brass or iron plates. Into these plates are put cranks, called heaves, which have hooks or forelocks, and keys, on the ends of their spindles. They are placed at such a distance from each other, that the workmen do not interfere with each other while turning their rope. The top of the breast-board is fixed to the top of strong posts well secured by struts or braces facing the lower end of the walk. At the lower end another breast-board fixed to the upright posts of a saddle, which may be fixed with struts or other similar cranks are placed in the holes of this breast-board. The whole goes by the name of the saddle; (see fig. 219). The top necessary for closing large cordage is too heavy to be held in the hand; it therefore has a long staff, which has a truck on the end. This rides on the ground; but even this is not enough in laying great cables. The top must be supported on a carriage, as shown in fig. 217, where it must lie very steady, and it needs attendance, because the struts are so heavy. The employment in attending to the manner in which the strands close behind the top; and in helping them by various methods. The top is, therefore, fixed to the carriage by lashing it with its staff to the top. The warp-post, or piece of soft rope, or strap, is attached to the handle of the top by the middle, and its ends are brought back and wrapped several times round the rope, in the direction of its twist, and bound down. This is shown at A, and it greatly assists the laying of the rope by its friction. This both keeps the top from flying too far from the point of union of the strands; and brings the strands more regularly into their places.

The first operation is warping the yarns. At each end of the walk are frames called warping frames, which carry a great number of reels or winches filled with rope-yarn. The yarns from the top-yarn end from each, till he has made up the number necessary for his rope or strand, and bringing the ends together, he passes the whole through an iron ring fixed to the top of a stake driven into the ground, and draw them through; and a knot is tied on the end of the handle, and a workman pulls it through this ring till the intended length is drawn off the reels. The end is made fast at the bottom of the warping stake, and the foreman comes back along the skein of yarns, to see that none are hanging slackener than the rest. He takes up in his hand such as are slack, and draws them tight, keeping them so till he reaches the upper end, where he cuts the yarns to a length, again adjusts their tightness, and joins them all together in a knot, to which he fixes the hook of a tackle, the other block of which is fixed to a firm post, called the warping stake, and stretched by this tackle, and then separated into its different strands. Each of these is knotted apart at both ends. The knots at their upper ends are made fast to the hooks of the cranks in the middle of the breast-board, the lower ends are fastened to the cranks in the slide. The slide itself is kept in its place by a tackle, by which the strands are again stretched in their places, and every thing adjusted, so that the slinger stands square on the walk, and then a proper weight is laid on it. The tackle is now cast off, and the cranks are turned at both ends, in the contrary direction to the twist of the yarns. (In some kinds of cordage the cranks are turned the same way with the spinning twist). By this the strands are twisted and hardened up; and as they contract by this operation, the slide is dragged up the walk. When the foreman thinks the strands sufficiently hardened, he estimates by the motion of the slide, he orders the heavens at the cranks to stop. The middle strand at the slide is taken off from the crank, this crank is taken out, and a piece of nothing at D, fig. 216. The other strands are taken off from their cranks, and are all joined on the hook which is now in the middle hole. The top is then placed between the strands, and being pressed home to the point of the cranks, the carriage is placed under it, and it is firmly fixed
ROPE-MAKING.

Some weight is taken off the sledge. The heavers now begin to turn at both ends. Those at the tackle-board continue to turn as they do at first, until they reach the point at which the sledge turns in the opposite direction to their former motion, so that the cranks at both ends are now turning one way. By the motion of the sledge-crank, the top is forced away from the knot, and the rope begins to close. The heavers at the upper end restore to the strand the twist which they are constantly losing by the laying of the rope. The workmen judge of this by making a chalk mark on the strands at points of the strand, where they lie on the stake; which are set up along the walk for their support. If the twist of the strands is diminished by the motion of closing, they will lengthen, and the chalk mark will move away from the tackle-board; but if the twist increases by turning the cranks at the tackle-board, the strands will shorten, and the mark will come nearer to it.

As the closing of the rope advances, the whole shortens, and the sledge is dragged up the walk. The top moves faster, and at last reaches the upper end of the walk, the rope being now laid. In the mean time, the sledge has moved away, and the chalk mark marks the place where it was when the laying began.

These motions of the sledge and top must be exactly adjusted to each other. The rope must be of a certain length. Therefore the sledge must always be at least as far from the top as the moment the rope should be laid; that is, the top should be at the tackle-board. In this consists the address of the foreman. He has his attention directed to both ways. He looks at the strands, and when he sees any of them hanging lower than the others, he calls to the heavers at the tackle-board to heave more upon that strand. He finds it more difficult to regulate the tension of the top. It requires a considerable force to keep it in the angle of the strands, and it is always disposed to start forward. To prevent or check this, some strands of soft rope are brought round the staff of the top, and fastened to the sledge at several times round the rope behind the top, and kept firmly down by a lanyard or bondage, as is shown in the figure. This both holds back the top, and greatly assists the laying of the rope, as it enables the strands to fall into their places, and keep close to each other, which is sometimes very difficult, especially in ropes composed of more than three strands. It will greatly improve the laying of the rope, if the top has a sharp, smooth, tapering pin of hard wood, pointed at the end, projecting so far from the middle of its smaller end, that it gets in between the strands which are closing, and supports them, and makes their closing more gradual and regular. The top, its notches, the pin, and the warp or strap, which is lapped round the rope, are all smeared with grease or soap to assist the closing.

The foreman judges of the progress of closing chiefly by his acquaintance with the walk, knowing that when the sledge is abreast of a certain stake, the top should be abreast of a certain other stake. When he finds the top far from the walk, he slackens the motion at the tackle-board, and makes the men turn briskly at the sledge. By this the top is forced up the walk, and the laying of the rope accelerates, while the sledge remains in the same place, because the strands are losing their twist, and are lengthening, while the closed rope is shortening. When, on the other hand, the rope begins to close, and fears that it will be at the head of the walk before the sledge has got to its proper place, he makes the men heave briskly on the strands, and the heavers at the sledge-crank work softly. This quickens the motion of the sledge by shortening the strands; and by thus compensating what has been undone, the sledge and top come to their places at once, and the work appears to answer the intention.

When the top approaches the tackle-board, the heaving at the sledge could not cause the strands immediately behind the top to close well, without having previously produced an extravagant degree of twist in the intermediate rope. The effort of the crank must therefore be assisted by men stationed along the rope, each furnished with a tool called a wudder. This is a stout oak stick, about three feet long, and used as a driving-stick. The rope is laid round the sides of the cranks, and the wudders keep their eye on the men at the crank, and make their motion correspond with his. Thus they send forward the twist produced by the crank, but still further in the direction of the cranks' motion.

Such is the general and essential process of rope-making. The fibres of hemp are twisted into yarns, that they may make a line of any length, and stick among each other with a force equal to their own cohesion. The yarns are made into cords of permanent twist by laying them; and that we may have a rope of any degree of strength, many yarns are united in one strand, for the same reason that many fibres were united in one yarn; and in the course of this process it is our power to give the rope a solidity and hardness which make it less penetrable by water, and which increase its strength. Some of these purposes are inconsistent with others; and the skill of a rope-maker lies in making the best compensation, so that the rope may on the whole be the best in point of strength, pliability, and durability, and the quantity of hemp in it can produce.

The following rule for judging of the weight which a rope will bear is not far from the truth. It supposes them rather too strong; but it is so easily remembered that it may be of use.

Multiply the circumference in inches by itself, and take the fifth part of the product, it will express the tons which the rope will carry. Thus, if the rope has 6 inches circumference, 6 times 6 is 36, the fifth of which is 36 divided by 5, or 7.2 tons; on which sir Charles Knowles made his experiments 34 X 34 = 1025, the quarter of which is 9.05 tons, or 4592 pounds. It broke with 4550.

This may suffice for an account of the mechanical part of the manufacture. But we have not yet noticed of the operation of tarring; and our reason was, that the methods practised in different rope-works are so exceedingly different, that we could hardly enumerate them, or even give a general account of them. It is evidently proper to tar in the state of twine or yarn, this being the only way that the hemp could be transformed. The yarn is made to wind off one reel, and having passed through a vessel containing hot tar, it is wound up on another reel; and the superfluous tar is taken off by being drawn through a box, well surrounded with spongy oakum; or it is tared in skains or haws, which are drawn by a capstern through the tar-kettle, and through a hole formed of two plates of metal, held together by a lever loaded with a weight.

It is established beyond a doubt, that a tarred cordage when new is stronger than white, and that the difference increases by keeping. The following experiments were made by Mr. Du Hamel at Rochefort over a cordage of three inches (French) in circumference, made of the best Riga hemp.

Mr. Du Hamel says, that it is decided by experience, 1. That white cordage in continued service is one-third more durable than tarred. 2. That it retains its force much longer while kept in store. 3. That it resists the ordinary injuries of the weather one-fourth longer.

We know one remarkable fact: in 1758 the shrouds and stays of the Silver hull at Portsmouth dock-yard were overthrown, and when the working and service were taken off, they were found to be of white cordage. On examining the store-keeper's books, they were found to have been formerly the shrouds and rigging of the Royal William, of 140 guns, built in 1715, and rigged in 1716. She was thought top-heavy, and unfit for sea, and unrigged, and her stores laid up. Some few years afterwards, her shrouds and stays were fitted on the Silver hull, where they remained in constant and very hard service for about 30 years, while every tarred rope about her had been repeatedly renewed.

Why then do we tar cordage? It is chiefly serviceable for cables and ground tackle, which must be continually wetted, and even soaked. The result of careful observation is,

1. That white cordage, exposed to be alternately very wet and dry, is weaker than tarred cordage. 2. That cordage which is
sions, continue till November or December. Hence the name monthly rose, double virgin rose, &c.

4. The damascena, including the red damask rose, white damask rose, blue-blooded rose, red rose, white rose, red rose, &c. These varieties, like those of the other sorts, are of the French race, and have mostly been selected from the wild rose of the Alps or the Pyrenees. The flowers are usually large, and very beautiful. Marbled rose grows from four to five feet high, having brown branches, with but few prickles; and a large, double, dark crimson and red flower.

5. The Lutea, including the red and yellow Austrian rose, yellow Austrian rose, yellow rose, double yellow rose.

6. The centifolia, or hundred leaved red rose, &c. The varieties are: common Dutch hundred-leaved rose, bluish hundred-leaved rose.

7. The provincialis, or Provence rose. The varieties are: common red Provence rose, pale Provence rose; both of which have large and small leaves prunus, and larger petals than the following sort. Cabbage Provence rose, having the petals closely folded over one another like cabbages; Dutch cabbage rose, very large, and cabbages tolerable; chalking Provence rose, small rose, producing remarkably large, white, and yellow flowers. All these are large double red flowers, somewhat globular at first blooming, becoming gradually a little spreading at top, and are all very ornamental fragrant roses.

8. The muscosa, or moss Provence rose, supposed by some a variety of the common rose, having the calyx and upper part of the pedicel surrounded with a rough moss-like substance, exciting a curious singularity.

9. The cinuncer, or cinumrose. There are varieties with double-flowers.

10. The alpina, or Alpine inermis. This species, as being free from all kind of attachment common to the other sorts of roses, is esteemed as a singularity; and from this property is often called the virgin rose.

11. The Carolina, or Carolina, Virginia rose, &c. grows six or eight feet high, or more. The varieties are: dwarf Pennsylvania rose, double red flowers, American pale-red rose. These species, and varieties grow naturally in different parts of North America; they effect a fine variety, in our gardens, and are in estimation for their late flowering property, as they often continue in bloom from August till October; and the flowers are succeeded by numerous red berry-like hips in autumn, causing a variety all winter.

12. The villosa, or villosa apple-bearer rose, grows six or eight feet high. This species merits admittance into every collection as a curiosity for the singularity of its fruit, both for variety and use; for having a thick coat of an agreeable acid relish; this is often made into a tolerably good sweetmeat.

13. The pimpinellifolia, or burnet-leaved rose. These varieties have red flowers, and white flowers. They grow wild in England, and are cultivated in shrubbery for variety.

14. The spinissa, or most spiny, dwarf burnet-leaved rose, commonly called Scotch rose. The varieties are: common white-flowered, red-flowered, striped-flowered, marble-flowered. They grow naturally in England, Scotland, &c. The first variety, rises near a yard high, the others, but one or two feet, all of which are single-flowered; but the flowers, being numerous all over the branches, make a pretty appearance in the collection.

15. The eglatina, eglatine rose, or sweet-brier. The varieties are: common white-flowered, double-flowered, bluish double-flowered, yellow double-flowered, &c. This species grows naturally in some parts of England and Switzerland. It thrives in every garden for the odoriferous property of its leaves; and should be planted in the borders, and other compartments contiguous to walks, or near the habitation, where the plants will impart their refreshing fragrance very profusely all around; and the young branches are excellent for improving the colour of nosegays and bouquets.

16. The moschata, or musk rose, supposed to be a variety only of the evergreen musk rose, has all the branches terminated by large umbellate clusters of pure white musk-scented flowers. In August, it is remarkable for producing them numerously in clusters, continuing till succession till October or November.

17. The sempervirens, or evergreen musk rose. The sempervirent property of this elegant species renders it a curiosity among the rose tribe; it also makes a fine appearance as a flowering shrub. There is one variety, the delicious musk rose, sub-vexillaria. This species and variety flower in August, and is remarkable for producing them numerously in clusters, continuing till succession till October or November.

18. The scented flowers, or deep-red China rose, a most beautiful little plant, and well deserving the appellation of ever-blooming.

19. The chinensis, or pale China rose, which flowers almost the whole year. These last species we suppose to be so tender, as always to require the shelter of a green-house; but we can say from experience that they are nearly as hardy as any of our English roses.

20. The white musk roses are used in medicine. The former distilled with water yields a small portion of a butyrazeous oil, whose flavour exactly resembles that of the rose itself. This oil, and the distilled water is known by the name of musk-rose.

21. The deciduous musk rose, sub-vexillaria. These roses also, besides the cordial and aromatic virtues which reside in their volatile parts, have a mild purgative, one which remains entire in the decoction after distillation. The red rose, or contrary, has an astrigent and gratefully corrosivating virtue.

**ROSE.** See Rosa.

**ROSEMARY.** See *Rosmarinus*.

**ROSDULAS.** A genus of the class and order pentandria monogynia. The calyx is five-leaved, corolla five-petalled; anthers scrothiform; capsule three-valved. There is one species, *Rosma...*, of the genus of the monogynia order, in the dandrus class of plants, and in the natural method ranking under the 42d order, verticillae. The corolla is unequal, with its upper lip biplicate; the capsule is 16-seeded, each having a small dent. There are two species, the officinalis and chilensis. There are two varieties, the first sort, one with white-streped leaves, called the silver-rose.
ROT

mire, and the other with yellow, whence it is called the gold-striped rosemary. These plants grow naturally in the southern parts of France, Spain, and Italy; where, upon dry rocky soils near the sea, they thrive prodigiously, and perfume the air in such a manner as to dissolve hang over, or lie on the surface of the land. They are, however, handy enough to bear the cold of our ordinary winters, provided they are planted upon a level, dry, gravelly soil, on which they all endure the cold much better than in a rich ground, where growing more vigorously in summer, they are more apt to be injured by frost in winter; nor will they have such a strong aromatic smell as those on a dry and barren soil. They are to be propagated either by or corolla; the capsule is trilocular and polyspermy. There is one species, an annual of the East Indies. 

ROTA, a genus of the monogynia order, in the trinatria class of plants. The calyx is tricarpellate, the capsule is trilocular, and polyspermous. There is one species, an annual of the East Indies. 

ROTANG. See Calamus. 

ROTATION, in geometry, a term chiefly applied to the reduction of any surface or solid to a fixed and immovable line, which is called the axis of its rotation; and by such rotations it is, that solids are conceived to be generated.

The ingenious M. de Moivre shows how solids, thus generated, may be measured or cubed. His method is this: for the fluxion of such solids, take the product of the fluxion of the axis, multiplied by the circulare base; and suppose the ratio of a square to the circle inscribed in it to be \( \pi \); then the equation expressing the nature of any circle, whose diameter is \( d \), is \( \pi = \frac{4d}{\pi} \). Therefore, \( \frac{4d^2}{\pi} = \pi \) is the fluxion of a portion of the sphere; and, consequently, the portion itself \( \frac{4d^2}{\pi} = \pi \), the circumscribed cylinder \( 4d \pi = 2\pi \); and therefore the portion of the sphere is to the portion of the circumscribed cylinder, as \( 4d \pi = 2\pi \) to \( d \pi = \pi \).

ROTHIA, a genus of the class and order 1-monogynia polychaeta aquatic. The calyx is many-leaved in a single row; woolly recept. in the ray chaffy in the disk villose-seeds; in the ray baid in the disk papose. There is one species, Rotondos, or Rotundo, in architecture, an appellation given to any building that is round both within and without, whether it is a church, a sacon, or the like. 

ROTTBOELIA, a genus of the dignity order, in the triandria class of plants. The racis is jointed, rounded, and in many cases infirm: the calyx is ovate, lanceolate, flat, or orbicular, and the distance of the stamens or alternates, on the winding racis. There are 17 species, of grasses of Africa and the East Indies. 

ROTTEN-STONE, a mineral found in Derbyshire, and used by mechanics for all sorts of finer graining and polishing, and sometimes to cut stones. According to Ferber, it is a tripoli mixed with calcareous earth. See Tripoli. 

ROUND, in a military sense, signifies a wall which some officer, attended with a party of soldiers, takes in a fortified place around the ramparts, in the nighttime, in order to see that the sentries are watchful and every thing in good order. 

The centres are to challenge the rounds at a distance, and rest their arms as they pass, so that none come near them; and when the round comes near the guard, the sentry calls aloud, who comes there? and being answered, the rounds; he says, stand; and then calls the corporal of the guard, who draws his sword, and asks, who comes there? and when he is answered, the rounds, he who has the word advances, and the corporal receives it with his sword pointed to the giver's breast. In strict garrison the rounds go every quarter of an hour. 

RONDÉLAY, a kind of ancient poem, thus termed, according to Menage, from its form, because it turns back again to the first verse, and thus goes round. This is a little known among us, but is very common among the French, who call it rondéau. It consists commonly of thirteen verses, eight whereof are in one rhyme, and five in another. It is divided into couples, at the end of the second and third of which the beginning of the roundelay is repeated, and that if possible in an equivocal or passing sense. 

ROY, in law. See RIOT.

ROSEBUM, a genus of the octandria monogynia class and order. The calyx is four-leaved; corolla one-petalled, bell-shaped, four-cleft, inferior; berry quadrangular, many seeded. There is one species, a shrub of St. Malo, called Rosebum. 

ROXburgia, a genus of the octandria monogynia class and order. The calyx is four-leaved; corolla four-petalled, nectaries four, aw-shaped; anthers linear; capsule one-celled, two-valved; seeds many. There is one species, native of Ceylon and Madeira.

ROVENIA, a genus of the dignity order, in the dianthera class of plants; and in the natural method ranking under the 18th order, bicarpellae. The calyx is of 5 parts; the corolla monopetalous, with the limb rounded; the capsule is unilocular and quadrivalved. There are seven species, herbs of the Cape. 

RUBIA, madder, a genus of the monogynia order, in the tetrameria class of plants; and in the natural method ranking under the 47th order, stellate. The corolla is monopetalous and campanulate; and there are two monoepispermy berries. There are seven species, of which the principal is the fimbriat, or dyer's madder, so much used by the dyers and callico-printers. This hath a perennial root, and annual stalk: the root is composed of many long, thick, succulent fibres, almost as large as a man's little finger; these are joined at the top in a head like asparagus, and run very deep into the ground. From the upper part of this root, come out many side-roots, which extend just under the surface of the ground to a great distance, by which it propagates very fast; for these send up a great number of shoots, which, if carefully taken off in the spring soon after, they are above ground, become so many plants. These roots are of a reddish colour, somewhat transparent; and have a yellowish skin in the middle, which is tough, and of a bitterish taste. From this root arise many large four-cornered jointed stalks, which in good land will grow five or six feet long, and, if supported, sometimes seven or eight: they are armed with short horizontal prickles; and at each joint are placed five or six spear-shaped leaves: their upper surfaces are smooth; the branches are terminated by loose branching spikes of yellow flowers, which, when dry, become dark red stars. These appear in June, and are sometimes succeeded by seeds, which seldom ripen in England. For its principal uses, see Dyeing, and Calico Printing. 

RUBIACAE, an order of herbs. The virtues attributed to it are those of a deli-
gent and aperient; whence it has been usually ranked among the opening roots, and recommended in obstructions of the vesica, and couplings of the kidneys. It is an ingredient of the blood from falls or brumes, in the jaundice, and beginning dropsies. It is an ingredient in theicteric decoction of the Edinburgh pharmacopoeia. 

It is observable, that this root, taken internally, tingles the urine of a deep red colour; and in the Philosophical Transactions we have an account of its producing a like effect upon the bowels of animals who had it mixed with their food; all the bowels, particularly the more solid ones, were said to be changed, both externally and internally, to a deep red; but neither the flesh, nor carcases parts suffered any alterations: some of these bones were macerated in water for some time, and afterwards steeped and boiled in spirit of wine, lost none of their colour, nor communicated any tinge to the liquors. This root, therefore, contains a principle of great subtility of parts, and its medical virtues hence to deserve inquiry. The same trials, however, made by others, have not been found to produce the same effects as those above mentioned. Of late the root has come into great reputation as an emmenagogue. 

RUBRIC, in the canon law, signifies a title or article in certain ancient law-books; thus called because written; as the titles of the chapters of our natal bibles are, in red let-
ters. Rubrics also denote the rules and directions given at the beginning, and in the course of, the liturgy, for the order and manner in which the several parts of the office are to be performed. They are generally rules and special rubrics, a rubric for the communication, &c., in the Romish Missal and Breviary are rubrics for masses, for lands, for transfigurations, benedictions, commemorations, &c. 

RUBUS, the frondalis, a genus of the poly-
gynia order, in the icosandria class of plants; and in the natural method ranking under the 35th order, septicaim. The calyx is
RUBIDEXIA, dwarf sun-flower, in botany, a genus of the syngeccsis-polygonia frustansace class of plants, the compound flower of which is radiated; but the hema-thropic corolline of the disc are tubular and very numerous; the stamens are five very short calipiter filaments; and there is a small orbiculated seed after each of the hermaphro-dite corolline, and are all contained in the cup, a pale-blossomed receptacle. There are seven species.

RUDDER, in navigation, a piece of timber turning on hinges in the stern of the ship, and which, opposing sometimes one side to the water, and sometimes another, turns or directs the vessel in this way or that. See SHIP-BUILDING.

The rudder of a ship is a piece of timber hung on the stern-posts by four or five iron hooks, called pintles, serving for the bridle of a ship to turn her about at the pleasure of the steersman. The rudder being perpendicular, and withoutside the ship, another piece of timber is fitted to it at right angles, which comes into the ship, by which the rudder is managed and directed. This latter properly is called the helm or tiller; and sometimes, though improperly, the rudder itself. The power of the rudder is reducible to that of the lever. As to the angle the rudder should make with the keel, it is shown, that in the working of ships, in order to stay the ship bear up the soonest possible, the tiller of the rudder ought to make an angle of 55° with the keel. A narrow rudder is best for a ship's sailing, provided she can feel it; that is, be guided and turned by it: for a broad rudder will hold much water when the helm is put over to any side; but if a ship has a fat quarter, so that the water cannot come quick and strong to her rudder, she will require a broad rudder. The aft-most part of the rudder is called the rame of the rudder.

RUELLIA, in botany, a genus of the angloperma order, in the dalyamia class of plants; and in the natural method, ranking under the 4th order, persontace. The calyx is quickeperatic; the corolla sub-campanulate; the stamens approaching together in pairs; the capsule springing asunder by means of its elastic septum. There are 43 species, shrubs of the East and West Indis.

RUFF, See PERCA.

RUFF; See TERNINGA.

RUPEA, a genus of the polyandria order, in the monadophila class of plants; and in the natural-method running under the 37th order, columnifere. The calyx is double; the external are triplici.
Having learned how much the piece is square, look for that number on the line of the timber-measure; the space thence to the end of the rule is the length which, at that breadth, makes a foot of timber; and nine inches square, the length necessary to make a solid foot of timber, is 21/2 inches. If the timber is small, and under nine inches square, seek the square in the upper rank of the table, and immediately under it are the feet and inches that make a solid foot. If the piece is not exactly square, but broader at one end than the other, the method is to add the two together, and take half the sum for the side of the square. For round timber the method is to get it round with a string, and to allow the fourth part for the side of the square; but this method is erroneous, for thereby you lose nearly one-fifth of the true solidity; though this is the method at present practised in buying and selling timber.

The mason's rule is twelve or fifteen feet long, in order to be applied under the need to regulate the courses, and make the ped- droits equal, &c.

Everard's slinding Rule. See Gauging.

RUM, a species of branly, or vivis spirit, distilled from sugar-canes. See Distillation, and Spirit.

RUMEN, in comparative anatomy, the stomach, or first stomach of such animals as chew the cud, whence called ruminant animals. See Comparative Anatomy.

RUMENI, dock, a genus of the trignyta order, in the hexandria class of plants; and in the natural method ranking under the 12th order, bocotrices. The calyx is triplicate; there are three connivent petals, and one tricrestous seed. There are 36 species; of which the most remarkable are: 1. The patient, commonly called patience rubbush. This was formerly much more cultivated in the British gardens than at present; the roots of this have been generally used for the monk's rubbush, and it has even been thought to be the true kind; but others supposed it to be a second sort sloe, and to be used as such. 2. The alpinus, or monk's rubbush, grows naturally on the Alps, but has long been cultivated in the gardens of this country. This has large roots, which spread and much interchange the offsets; it is a much thicker than the former, are of a very dark brown on the outside, and yellow within. 3. The aquatics, or water-dock, grows naturally in ponds, ditches, and standing waters, in many parts of Britain. It is supposed to be the herb Britannica of the ancients. 4. The acutus, or sharp-pointed dock (the oxytopathum of the shops); but the markets are supplied with roots of the common docks, which are uniformly gathered by those who collect them in the fields, where the kind commonly called butter dock (from its leaves being used to wrap up butter) is much more common than this. These plants are but seldom cultivated, and so easily multiplied by their numerous seeds, that they soon become troublesome weeds where they once get an entrance.

RUMINANT, in natural history, is applied to an animal which chews over again what it has eaten before; which is popularly called chewing the cud. Payer, in a treatise De Ruminantibus, says that there are some animals which really ru-

minate; as oxen, sheep, deer, goats, camels, lamas, and squirrels; and that there are others which only appear to do so, as mole, crickets, mice, beetles, crabs, mules, &c. The latter class, he observes, have their stom- passes composed of muscular fibres, by which the food is ground up and down and as in those which really ruminate. Mr. Ray observes, that ruminants are all four-footed, hairy, and having a long, external, and internal permanent horns, others with deciduous ones.

RUMPHIA, a genus of the monogenesis order, in the triandria class of plants, and in the natural method ranking with those of which the order is doubtful. The calyx is trin; the petals three; the fruit a triocular plum. There is one species, a tree of the East Indies.

RUNDLE, or Rundell. See Heraldry.

RUNDLET, or Rundlet, a small vessel, containing an uncertain quantity of any li- quor, from three to twenty galleons.

RUNNER, in the sea-language, a rope belonging to the ganet, and used for bolt- tackles. It is reeved in a single block, joined to the end of a pennant, and has at one end a hook to hitch into any thing; and at the other end a double block, into which is reeved the tail of the tackle, or the ganet, by which means it purchases more than the tackle would without it.

RUNNET, or Rensnet, is the juice or gastric fluid found in the stomachs of sucking quadrupeds, which as yet have received no other denomination than their mother's milk. In ruminating animals, which have several stom- ches, it is generally found in the last, though sometimes in the next to it. If the rumnet is dried in the sun, and then kept close, it may be preserved in perfection for years. Not only the rumnet itself, but also the stomach in which it is found, curnades milk without any previous preparation. But the common method is, to take the inner mem- brane of a calf's stomach, and well seized, to salt and hang it up in brown paper when this is used, the salt is washed off, then it is macc- nated in a little water during the night, and in the morning the infusion is poured into the 26th RUMINATIONE, p. 521, col. 3.

RUPA, a genus of the tetraneura monogyna class and order. There is no calyx; the petals are four; stamens inserted in the middle of the petals; pericarpium one-celled, two-seeded.

RUPERT'S DROPS, a sort of glass-drops with long and slender tails, which burst to pieces on the breaking off those tails in any part; said to have been invented by prince Rupert, and therefore called by his name. Concerning the cause of this surprising plan nonone scarcely any thing that bears the least appearance of probability has been of- fered. Their explosion is attended in the dark with a flash of light; and, by being boiled in oil, the drops are deprived of their explosive quality.

RUPPIA, a genus of the tetragna order, in the tetradria class of plants; and in the natural method ranking under the 15th order, inanimate. There is neither calyx nor corolla; but four pedicelled seeds. There is one species.

RUPTURE, in surgery, the same with hernia. See Surgery.

RUSCUS, hrake-holly, or butcher's broom, a genus of the monogynia order, in the dicadria class of plants, and in the natural method ranking under the 11th order, samen- taceae. The male calyx is hexaplisp; there is no corolla; the nectarium is central, ovate, and perforated at the top. The fru- it is a small berry, covered with a viscid, a trilocular two-seeded berry. There are five species. The most remarkable is the aculeatus, or common butcher's broom, common in the woods in many parts of England. As this plant grows wild in most parts of England, it is rarely admitted into gardens; but if some of the roots are planted under tall trees in large plantations, they will spread into large clumps; and as they retain their leaves in winter, at that season they will have a good effect. The seeds of this plant generally lie a year in the ground before they vegetate; and the plants so raised are long before they arrive at a size large enough to make any figure, and therefore it is much bet- ter to transplant the roots. The root of this plant is accounted aperient, and in this in- tention is sometimes made an ingredient in dirty-cookings and diet-drinks, for opening slight obstructions of the visera, and promoting the fluid secretions. This plant is used by the butchers for besoms to sweep their blocks. Hucksters place the boughs round their ha- ries, and use them to clean their mics; for they cannot make their way through the prickly leaves.

RUSH, in botany. See Juncus.

RUSSELIA, a genus of the dicademia angiosperma class and order. The calyx is five-leaved; corolla tube, very long; capsu- late acuminate. There is one species, a shrubby plant of the Havannah.

RUSSIA COMPANY, in commerce. See Company.

RUST, the oxide of a metal. Iron, for instance, when exposed to the air, soon be- come oxidized, and glassy, tinged with a brown or yellow powder, well known by the name of rust. This change is occasioned by the gradual combination of the iron with the oxygen of the atmosphere, and, accord- ing to new chemistry, it is now deno- minated the oxide of iron.

RUSTIC, in architecture, implies a ma- nner of building in imitation of nature, rather than according to the rules of art.

RUTA, rue, a genus of the monogeny order, in the dicadria class of plants; and in the natural method ranking under the 26th order, multisiquitica. The calyx is quin- quepartite; the petals concave; the recepta- cle surrounded with 10 malliform pori; the capsule is bilocular. In some forms the fifth part of the number is excluded. There are seven species, of which the most remarkable is the hortensis, or common broad-leaved garden rue, which has been long cultivated for medicinal use.

Rue has a strong ungrateful smell, and a bitterish penetrating taste; the leaves, when full of vigour, are extremely acrid, insomuch as to inflame and blister the skin, if much handled.

RUTHILE, or Rue, found in Hungary, Italy, and France. It is generally crystal-
lized. The primitive form of the crystals is a rectangular prism, whose base is a square, and the form of its molecules is a triangular prism, whose base is a right-angled isosceles triangle, and the height is to any of the sides of the base about the right angle, nearly as three to five. Specific gravity from 4.18 to 4.24. It is not affected by the mineral acids.

**RUYSCHIA**, in botany, a genus of the monogynia order, in the pentandria class of plants; and in the natural method ranking with those that are doubtful. The calyx is pentahylous; the corolla is pentapetalous; and the berry many-seeded. There are two species, parasitical shrubs of Guiana.

**RYANIA**, a genus of the polyandria monogynia class and order. The calyx is five-leaved; corolla none; stigma four; berry suberous, one-seeded, many-seeded. There is one species, a tree of Trinidad.

**RYE.** See **SECALE**.

**RYNCHOPS, skinner, in ornithology,**

S, the eighteenth letter of our alphabet, in abbreviations stands for societies, or persons; as R. S. for regius societatis socius, i.e. fellow of the royal society. In medicinal prescriptions, S. A. signifies secundum artum, i.e. according to the rules of art; and in the notes of the antidots, S. stands for Sextus; S. C. for secundus consultum; S. P. Q. R. for senatus populusque Romanus; S. S. for stratum super stratum, i.e. one layer above another alternately; S. V. B. E. Q. V. for si vales bene et ego quoque vales, a form used in Cicero's time, in the beginning of letters.

Used as a numeral, S. antiently denoted seven; in the Italian music, S. signifies solo; and in books of navigation, S. stands for south; S. E. for southeast; S. W. for south-west; S. S. E. for south-south-east; S. S. W. for south-south-west. See **COMPASS**.

**SABELLA, a genus of vermues testacea;** animal a nereis, with a ringed mouth, and two thicker tentacles behind the head: shell tubular, composed of particles of sand, broken shells, and vegetable substances united to a membrane by a gluttonous cement. There are 24 species.

**SABELLIANS, a sect of Christians of the third century, that is, the opinioned Sabellius, a philosopher of Egypt, who openly taught that there is but one person in the Godhead.**

**SABLE.** See **MUSTELA**.

**SABLE.** See **HERALDRY**.

**SABURRE.** See **GIRR**.

**SAC BUT, a bass wind-instrument, resembling the trumpets, so contrived as to be capable of being drawn out to different lengths, according to the acuteness and gravity of the scale required.**

The sacbut is usually about eight feet long, and when extended to its full length, about fifteen. There are, however, sacbuts of different sizes to execute different parts; particularly a small one called by the Italian trombone piccolo, and the Germans klein alt possema, proper for the counter-tenor.

**SACCHARINE ACID. See **OXALIC** **ACID**.

**SACCHARUM, sugar, or the sugar-cane;** a genus of the digynia order, in the triandria class of plants; and in the natural method ranking under the 4th order, gramina. The calyx is two-valved; the corolla is also bivalved. There are eleven species of this genus. The most remarkable is the officinarum. It is a native of Africa, the East Indies, and of Brazil, whence it was introduced into Europe. In India islands soon after they were settled. In the manner of their growth, form of their leaves, and make of their panicle, the sugar-canes resemble the reeds which grow in wet marshy grounds in England, or elsewhere; except that the canes are far larger, and, instead of being hollow as the reeds, are filled with a white pith, containing the sweet juice or liquid, which stamps such value upon these plants. The intermediate distance between each joint of a cane is of different lengths, according to the nature of the soil, richness of the manure, and different temperature of the weather during its growth; it seldom exceeds, however, four inches in length, and an inch in diameter. The length of the whole cane likewise depends upon the above circumstances. It generally grows to perfection in about fourteen months, when its height, at a medium, is about six feet, sometimes more, sometimes less. The body of the cane is strong, but brittle; of a fine straw-colour, inclining to a yellow. The extremity of each is covered, for a considerable length, with many long sharp spines, which generally are sawed on their edges; the middle longitudinal ribs being high and prominent. The sugar-cane is propagated by planting cuttings of it in the ground in furrows, dug parallel for the longest part, and let parallel and level, and even, and are covered up with earth; they soon shoot out new plants from their knots or joints; the ground is to be kept clear, at times, from weeds; and the canes grow so quick, that in eight, ten, or twelve months, they are fit to cut for making of sugar from them. When ripe, they cut off the reeds at one of the joints near the roots; they are then cleared of the leaves, and tied up in bundles, and sent to the mills, which are worked either by water or horses.

The bottom part of the sugar-cane top is about the thickness of one's finger; and as it contains a good deal of the natural sweetness of the plant, it is usually cut into pieces of an inch and a half long, and given to the saddle-horses in the West Indies. It is very nourishing food, and fattens them space. The mill-horses, mules, and asses, are likewise fed, during the sunny days, on sugar-cane tops and the skimming of the sugar-coppers; which last must be administered sparingly at first, for fear of gripping, and perhaps killing them. For the manufacture, &c., of sugar, see **SUGAR**.

**SACCOLATS, salts formed from the saccharic acid, and but little known.**

1. **Saccolat of potas; small crystals soluble in eight times their weight of water.**

2. **Saccolat of soda; the same soluble in five times their weight of water.**

**Saccolat of ammonium; has a sourish taste; heat separates the ammonium.**

**Saccolat of lime, of barytes, of magnesia, and of alumina, are all insoluble in water.**

**SACK of wool; a quantity of wool containing just twenty-two stone, and every stone fourteen pound.**

In Scotland, a sack is twenty-four stone, each stone containing sixteen pounds.

**SACK of cotton-wool; a quantity from one hundred and a half to four hundredweight.**

**SACKS of earth, in fortification, are canvas bags filled with earth.** They are used in making intrenchments in haste, to place on parapets, or the head of the breaches, &c., or to repair them, when beaten down.

**SACLACTIC ACID.** This acid was discovered by Scheele in 1780. After having obtained oxalic acid from sugar, he wished to examine whether the sugar of milk would furnish him the product. Upon four ounces of pure sugar of milk, finely powdered, he poured twelve ounces of diluted nitric acid, and put the mixture into a large glass retort, which he placed in a sand-bath. A violent effervescence ensuing, he was obliged to remove the retort from the sand-bath till the commotion ceased. He then continued the distillation till the mixture became yellow. As no crystals appeared in the liquor remaining in the retort after standing two days, he repeated the distillation as before, with the addition of eight ounces of nitric acid, and continued the operation till the yellow colour, which had disappeared on the addition of the nitric acid, returned. The liquor in the retort contained a white powder, and when cold, was observed to be thick. Eight ounces of water were added to dilute this liquor, which was then filtered, by which the white powder was separated; which being eluted and dried, weighed 74 drachms. The filtrated solution was evaporated to the consistency of a syrup, and, again subjected to distillation, with four ounces of nitric acid as before; after which, the liquor, when cold, was observed to contain many small, colourless, sour crystals, together with some white powder. This powder being separated, the liquor was again distilled with more nitric acid, and a genus belonging to the order of anseres. The bill is straight; and the superior mandible much shorter than the inferior, which is truncated at the point. The species are two, viz. the nigra and fulva, both natives of America. The fulva is perpetually flying and skimming, in and out of which it scoops small fish with its lower mandible; in stormy seasons it frequents the shores in search of shell-fish, See Plate Nat. Hist. fig. 348.
as before; by which means the liquor was rendered capable of yielding crystals again; and by one distillation more, with more nitric acid, the whole of the liquor was converted into a volatile nature; he therefore called it the acid of sugar of milk. It was afterwards called saccacic acid by the French chemists. Fourcroy has lately given it the name of mucous acid, because it is obtained by treating gum arabic, and other mucilaginous substances, with nitric acid.

Mr. Hermstadt, of Berlin, had made similar experiments on sugar of milk at the same time with Scheele, and with similar results; but he concluded that the white powder which he obtained was nothing else than an oxalte of lime with excess of acid, as indeed Scheele himself did at first. After he became acquainted with Scheele's conclusions, he published his opinions on the subject; but his proofs are very far from establishing it, or even rendering its truth probable. He acknowledges himself, that he has not been able to decompose this supposed acetate; and that he possesses properties distinct from the oxalic acid; but he ascribes this difference to the time which it contains; yet all the time which he could discover in 240 grains of this salt was only 20 grains; and if he employed it as a carbonat (as it probably was), these 20 must be reduced to 11. Now Moreau has shewn, that oxalic acid, containing the same quantity of lime, exhibits very different properties. Besides, this acid, whatever it is, when united with lime, is separated by the oxalic, and must therefore be different from it; as it would be absurd to suppose that an acid could displace itself. The saccacic acid must therefore be considered as a distinct acid, since it possesses properties distinct from the oxalic acid.

1. Saccacic acid may be obtained by the following process: Upon one part of granular oxalic acid, or other similar gum, previously put into a retort, pour two parts of nitric acid. Apply a stream of cold water until the whole takes a containing a little nitrous gas and carbonic acid gas comes over; then allow the mixture to cool. A white powder gradually precipitates, which may easily be separated by filtration. This powder is saccacic acid.

2. Saccacic acid, thus obtained, is under the form of a white gritty powder, with a slightly acid taste.

SALT, or saccacic acid, as in the form of a white powder, or in the form of crystals. SALT is a natural and a mineral acid, which is contained in a great variety of plants.

The solution has an acid taste, and reddens the infusion of turnsole. Its specific gravity, at the temperature of 33.7, is 1.005. The compounds which it forms with carbon, alkali, and metallic oxides are denominated saccates.

SACERON. See CROCEUS. SAGAPENUM, guna resinus. See PHARMACY.

SAGATHEE, in commerce, a slight kind of woolly stuff, tender, or ratteen, sometimes mixed with a little silk. SAGE. See SALVIA.

SAGNE, a Russian long measure, five inches of which make a verst. The sagne is equal to seven English feet.

SAGENILE. See RUTHILE.

SAGINA, perfoliata, a genus of the terebinth family, in the terebrata class of plants, and in the natural method ranking under the 22d order, caryophyllales. The calyx is triphialous; the petals four; the capsule is unilocular, quadrivalved and polyspermous.

There are 5 species.

SAGITTA, in astronomy, the arrow or dart, a constellation of the northern hemisphere, near the eagle. See ASTRONOMY.

SAGITTA, in trigonomotry, the same with the versed sine of an arch.

SAGITTARIA, overhand, a genus of the polyandria order, in the monoece class of plants, and in the natural method ranking under the fifth order, tripetalaeodae. The male calyx is triphialous; the corolla triphialous; the filament generally about 14; the female calyx is triphialous; the corolla triphialous; many pistils; and many naked seeds. There are five species, of which the most remarkable is the sagittalia, growing naturally in the parts of England. The root is composed of many strong fibres, which strike into the mud; the footstalks of the leaves are in length proportionable to the depth of the water in which they grow; so they are sometimes almost a yard long; they are thick and furcous; the leaves, which float upon the water, are shaped like the point of an arrow, the two cars at their base spreading wide and slender, and are very sharp-pointed. There is always a link at the lower part of the root, growing in the solid earth beneath the mud. This bulb consists of a considerable part of the food of the Chinese; and upon that account they cultivate it. Horses, goats, and swine, eat it; cows are not fond of it.

SAGITTIARUS, the archer, in astronomy, the ninth sign of the zodiac. See ASTRONOMY.

SAGO, a simple brought from the East Indies, of considerable use in diet as a restorative. It is produced from the pitch of a kind of palm which grows in the East Indies, called the cypsa cirrhata. See CYCAS, STARCH, &c.

SAIL, in navigation. See Ship-building. SAIL. If a man agrees for the purchase of goods, he shall pay for them before he carries or by the same term of a credit is expressly agreed upon.

If one man says the price of an article is 100l. and the other says I will give you 100l. but does pay not immediately, it is at the option of the seller whether he shall have it or no, except a day was given for the payment.

If a man upon the sale of goods, warrants them to be good, the law annexes to this contract a tacit warranty, that if they are not so, he shall make compensation to the purchaser; yet if the vendor knew the goods to be unsound, and has used any art to disguise them, or if in any respect they differ from what he represents them to be to the purchaser, he shall be answerable for their goodness, though no general warranty will extend to those defects that are obvious to the senses.

If two persons come to a warehouse, and one buys, and the other to procure him credit, promises the seller, if he does not pay him, I will; this is a collateral undertaking, and void without writing, by the statutes of frauds; but if he says, let him have the goods, I will be your pay-master, this is an absolute undertaking as for himself, and he shall be intended to be the real buyer, and the other to act only as his servant. 2 T. R. 73.

After earnest is given, the vendor cannot sell the goods to another without a default in the vendor; and therefore if the vendor does not come and pay, and take the goods, the vendor ought to give him notice for that purpose; and then if he does not come and pay, and take away the goods in convenient time, his agreement is dissolved, and he is at liberty to sell them to any other person.

An earnest only binds the bargain, and gives the party a right to demand; but demand without payment of money is void. See arRENT, CONTRACT, &c.

SAL, see STARCH.

SALIANT, in fortification, denotes projecting. There are two kinds of angles: the one salient, which are those that present their point outward; the other re-entering, which have their points inward. Both of these kinds we have in bastions and star-work.

SALIENT. See HERALDRY.

SALIC, or SALIQUE LAW, the law salic, an antient and fundamental law of the kingdom of France, usually supposed to have been made by Pharamond, or at least by Clovis, in virtue of which males are only to inherit.

Du Halain, after a critical examination, declares it to have been an expedient of Philip II., and says, that the daughter of Lewis Huitin from inheriting the crown. Father Daniel, on the other hand, maintains that it is quoted by authors more antient than Philip the Long, and that Clovis himself is the author of it, and that it is partly related to a particular regard to the crown of France; it only imports, in general, that in sale land no part of the inheritance shall fall to any female, but the whole to the male sex. By sale lands, or inheritances, were antiently denoted, among us, all lands, by whatever tenure held, whether noble or base, from the succession to which women were excluded by the salic law: for they were by it admitted to inherit nothing but moveable and purchases wherever there were any males.

SALICURIA, a genus of the class and order monoece polyandria. The male is an anem; and the female, solitary; calyx four-lobed, stripe. There is one species, a tree of Japan.

SALICORNA, jointed glasswort, or saltwort, a genus of the monegovia order, in the monoece class of plants, and in the natural method ranking under the 22d order, holocaraceae. The calyx is ventricose at the base, a little swelling out and entire: there are no petals, but one seed. There are nine species, of which the most remarkable are:

1. The fruticosa, with obtuse points, grows
plentifully in most of the salt marshes which are overflowed by the tides in many parts of England. It is an annual plant, with thick, succulent, jointed stalks, which trail upon the ground. 2. The perennis, with a shrubby branching stalk, grows naturally in Shapely Island. They are perennial, and produce their flowers in the same manner as the former.

The inhabitants near the sea-coasts where these plants grow, cut them up toward the latter end of summer, when they are fully grown; and after having dried them in the sun, they burn them for their ashes, which are used in making of glass and soap. These herbs are by the country people called help, and promiscuously gathered for use.

SALIX. The fluid secreted in the mouth, which flows in considerable quantity during a repast, is known by the name of saliva. All the properties of this liquor which had been observed by philosophers before the middle of the 18th century have been collected by Haller; but since that time several additional facts have been related by Fourcroy, Du Tennetar, and Brugnatelli, and a very numerous set of experiments have been made by Mr. Siebold, 1797, in his Treatise on the Salivary System.

Saliva is a limpid fluid like water; but much more viscid: it has neither smell nor taste. Its specific gravity, according to Haller, is 1.0167; according to Siebold, 1.080. When agitated, it froths like all other adhesive liquids; indeed it is usually mixed with air, and has the appearance of froth.

It neither mixes readily with water nor oil; but by a mortar it may be so mixed with water as to pass through a filtre. It has a great affinity for oxygen, absorbs it readily from the air, and gives it out again to other bodies. Hence the reason why gold or silver, triturated with saliva in a mortar, is oxidized, as Du Tennetar has observed; and why the killing of mercury by oils is much facilitated by spitting into the mixture. Hence also, in all probability, the reason that saliva is so readily transferred to sores of the skin. Dogs, and several other animals, have constantly recourse to this remedy, and with much advantage.

When boiled in water, a few flakes of albumen are putrid. When evaporated, it swells exceedingly, and leaves behind it a thin brown-coloured crust; but if the evaporation is conducted slowly, small cubic crystals of muriat of soda, (common salt) are formed; and when the evaporation is completed, there remains behind a substance which resembles vegetable gluten, and which takes fire on burning coal, exhaling the odour of prussic acid, and of burning feathers. The viscidity of saliva, the affinity which it has of absorbing oxygen, and of being inspissated, and this glutinous residuum, announce the presence of animal mucilage as a component part.

When saliva is distilled in a rotort, it froths very much. 100 parts yield 50 parts of water nearly pure, then a little carbonat of ammonium, some oil, and an acid, which perhaps is the prussic. The residuum amounts to about 1.50 parts, and is composed of muriat of soda, phlegm and phosphat of lime.

When saliva is exposed to the air, it absorbs a considerable portion of it, a slight pellicle appears on its surface, it becomes muddly, and deposits some flakes, exhaling at the same time a strong ammoniacal odour.

Soon after it putrices, and becomes exceedingly acid.

The acids and alcohol inspissates saliva; the alkalies disengage ammomia; oxalic acid precipitates lime; and the nitrats of lead, mercury, and silver, precipitate phosphoric and muriatic acids.

From these facts, it follows that saliva, besides water, which constitutes at least four-fifths of its bulk, contains the following ingredients:

1. Muriat of soda.
2. Muriat of lime.
5. Phosphat of ammonium.

But it cannot be doubted that, like all the other animal fluids, it is liable to many changes from disease, &c. Brugnatelli found the saliva of a patient, labouring under an oblique vertebral disease, impregnated with oxalic acid.

The concretions which sometimes form in the salivary ducts, &c. and the tartar or bony crust which so often attaches itself to the teeth, are composed of phosphat of lime.

Such are the properties of human saliva. The saliva of the goat as analysed by Delachoner in 1789. He collected 12 ounces of it in the space of 24 hours by puncturing the salivary duct. Its colour was greenish-yellow; its feel soapy; it had a weak disagreeable smell, and a saline taste. Boiling water and alcohol coagulated it in part; as did the acids. When sulphuric acid was used, sulphat of soda was obtained. It perished in about 14 days; and when allowed to evaporate spontaneously, it left a black residue like earth. When distilled, it yielded an inodorous watery liquid, crystals of carbonat of ammonia, a thick black empyreumatic oil, carbureted hydrogen, and carbonic acid; and a charcoal remained.

It is rather surprising that no experiments have been hitherto made on the saliva of dogs; though the hydrophobia has been usually ascribed to the infusion of the saliva of that animal.
The salmon, this fish is prepared in different methods for sale, being sold both fresh and salted, as well as smoked, pickled, &c. &c.

3. Salmo fario, common trout. The trout is an inhabitant of cold and clear streams and lakes in most parts of Europe, and admits of considerable variety as to the tinge of its ground-colour and spots. Its general length is from six to fourteen inches, and its greatest length from ten to sixteen inches, and its colour yellowish-grey, darker or browner on the back, and marked on the sides by several rather distinct, round, bright red spots, each surrounded by a tinge of pale red. The general colour of the body is a purplish grey; the red spots much larger, more or less mixed with black, and the belly of a white or silvery cast; the fins are a pale purplish brown; the tail is furnished with several darker spots; the head is rather larger in proportion than that of the salmon, the scales small, and the lateral line straight. The female fish is of a brighter and more beautiful appearance than the male.

Mr. Pennant informs us that in the lake Llyn Padarn, near Caernarvon, the Wakes are trout marked with red and black spots as large as sixpences; and others unspotted and of a reddish hue, sometimes weighing near ten pounds; but these latter are said to be harder fish.

In general the trout prefer clear, cold, and bright-running waters, with a stony or gravelly bottom. It swims with rapidity, and, like the salmon, springs occasionally to a very considerable height in order to surmount any obstacle in its course. It lives on young small fishes, shell-fish, and aquatic insects, and is particularly delighted with May-flies (ephemeris), as well as with phryganea, gnats, and their larvae. It generally spawns in September, or in the colder parts of Europe, in October, and at those times gets around the roots of trees, stones, &c. in order to deposit its eggs, which are observed to be far less numerous than those of other river-fish. Yet the trout, asBloch observes, is a fish that adapts itself to the most various situations. It is, moreover, no doubt, to the circumstance of most of the venomous kind of fishes avoiding waters of so cold a nature as those which trout delight to inhabit; and their increase would be still greater were they not themselves of a voracious disposition, frequently preying even on each other.

The merit of the trout as an article of food is too well known to require particular notice. In this respect, however, as in other fishes, those are most esteemed which are natives of the clearest waters.

The stomach of this fish is uncommonly strong and thick; but this circumstance is observed to be no where so remarkable as in those found in some of the Irish lakes, and particularly in those of the county of Galway. These are called gillmore trout; on the most accurate examination, however, it does not appear that they are specifically different from the common trout; but by living much on shell-fish, and swallowing small stones at the same time, their stomachs acquire a much greater degree of thickness, and a kind of muscular appearance, so as to resemble a sort of gizzard.

Mr. Pennant observes, that it is a matter of surprise that the trout, though so common a fish, should appear to be unnoticed by the ancients, except Antonius, who is supposed to

...
have intended it by the name of salar. He mentions it, however, merely on account of its beauty, and without any thing relative to its merit as a food.

4. Salmo salar is, according to ancient belief, the least of the British species of this genus, and is frequently seen in the river Wye, in the upper part of the Severn, and in the rivers that run into it, in the north of England, and in Wales. It is by several anglists termed the fry of the salmon; but Mr. Pennant disposed of this opinion for the following reasons: first, it is well known that the salmon-fry never continue in fresh water the whole year, but, as they appear on the first escape from the spawn, all vanish on the first vertal flood that happens, which sweeps them into the sea, and leaves scarcely one behind; secondly, the growth of salmon-fry is so quick and so considerable as suddenly to exceed the bulk of the largest salmon; for example, the fry that have quitted the fresh water in spring, not larger than gudgeons, return into it again a foot or more in length; thirdly, the salmon obtains a considerable bulk before it begins to ascend the stream; on the contrary, are found both male and female of the common size, and are readily distinguished by being furnished with either the hard or soft roe; fourthly, they are found in the fresh waters all times of the year, and even at seasons when the salmon-fry have gained a considerable size. It is well known that at Shrewsbury (where they are called Samons), they are found in such quantities in the month of September, that a skilled angler, in a coracle, will take with a fry from twenty to thirty dozen in a day. They spawn in November and December, at which time those of the Severn push up towards the head of that river, quitting the smaller brooks, and return into them again when they have done spawning. They have a general resemblance to the trout, and must therefore be described comparatively.

The head is proportionally narrower, and the mouth smaller; the body deeper; the length seldom more than six or seven inches, or at most about eight and a half; the pectoral fins have generally but one large black spot, or occasionally a single small one attached to it; whereas the pectoral fins of the trout are more numerous marked; the spurious or fat fin on the back is never tipped with red, nor is the edge of the anal fin white; the spots on the body are fewer, and not so bright; the body is also marked from back to sides with six or seven large bluish bars; but this Mr. Pennant allows to be a certain character, as the same is sometimes observed in young trout; lastly, the tail of the salmon is much more forked than that of the trout. The salmon is very frequent in the rivers of Scotland, where it is called the parr. It is also common in the Wye, and is there known by the title of skirling or lairping.

5. Salmo salvelinus, salvelin trout. Length about twelve inches; shape resembling that of the salmon, but rather more slender; colour of the back dark-brownish green; of the sides, the back part pretty much olive, moderately distant, small, round, red spots, which are sometimes surrounded with a pale margin; belly red or orange-colour; pectoral, ventral, and anal fins the same, but with the two first rays white; dorsal and caudal fin blueish brown; adipose fin small, pale, and filiponed, scales rather small than large; lateral line straight; tail moderately bifurcated; both jaws of equal length; irides silvery. Native of mountainous lakes in several parts of Germany, and of several of the rivers in Silesia, and (of this species is the red chair of the English) in some of the lakes of our own country, as those of Westmoreland, &c. As in others of this genus, those which inhabit the clearest and coldest waters are observed to be of the mildest colours. It is a fish of great delicacy of flavour, and much esteemed as a food.

6. Salmo cephalus, smelt. Of this species there appear to be two varieties: one not exceeding the length of three or four inches; the other arriving at the general length of six, eight, or nine inches, and sometimes even to twelve or thirteen. The larger variety seems to be so frequently seen about the British coasts, and which is distinguished by Dr. Bloch under the name of cephala- licus, or sea-smelt. These fishes are found about our coasts throughout the whole year, and rarely go any great distance from the shores, except when they ascend rivers either at or some time before the spawning-season. It is observed by Mr. Pennant that in the river Thames and in the Dee, they are taken in great abundance in November, December, and January; but in other rivers not till February, spawning in the months of March and April. The smelt is a very elegant fish; its form beautifully taper; the skin thin, and the whole body, but particularly the head, semi-transparent; the colour of the back is of a bluish green, with a cast of blue, beneath which it is variegated with blue, and then succeeds the beautiful silvery gloss of the abdomen; the scales are small, and easily rubbed off; the eyes are silvery; the under jaw longer than the upper; in front of the upper are four large teeth, those in the sides of the jaws being small; the tail is forked. This fish is an inhabitant of the European seas; it has generally a peculiar odour, which in those of British growth is commonly peculiarly odorous. It is said a cucumber, but by some to that of a violet.

7. Salmo Greenlandicus, Greenland salmon. Length about seven inches, which it very much exceeds; shape elongated, contracting somewhat in the tail, and the sides; the dorsal fin placed in the middle of the back; fins rather large for the size of the fish; scales small; tail forked; colour pale-green, with a tinge of brown above; abdomen and sides silvery; in the male fish, just above the lateral line, is a rough fascia, beset with minute pyramidal scales standing upright like the pile of a shag. The use of this fish is highly singular, since it is affirmed that while the fish is swimming, and even when very near, on shore, two, three, or even as many as ten will be there, as if glued together, by means of this pile, insomuch that if one is taken, the rest are also taken up at the same time. This species swarms off the coasts of Greenland, Iceland, and Newfound-land, and is said to be one of the chief supports of the Greenlanders, and a sort of dinner at their most delicate feasts. The inhabitants of Iceland are said to dry a great many of these, and use them as a winter food for their cattle, whose flesh is apt to acquire an only flavour in consequence. This fish lives at sea the greatest part of the year; but in April, May, June, and July, comes in incredible shoals into the bays, where immense multitudes are taken in nets, from fifty to a hundred; when fresh they are by some said to leave the smell of a cucumber, though others affirm that the scent is highly unpleasant. They feed on small crabs and other marine insects, as well as on small herring, on which they are also observed to deposit their eggs.

8. Salmo thymallus, grayling salmon. This elegant species grows to the length of about eighteen inches, and is an inhabitant of the clearer and colder kind of rivers in many parts of Europe and Asia, particularly such as flow through mountainous countries. In England it is found in the rivers of Derbyshire; in some of those of the North; in the Tame near Ludlow; in the Lug and other streams near Leominster; and in the river near Chirchch in Haupstaire. In Lolland it is said to be very common, where the natives make use of its intestines instead of rennet, in preparing the cheese which they make from the milk of the reindeer.

This species of the grayling resembles that of the trout, but is much more slender; its colour is a beautiful silvery grey, with numerous longitudinal deeper stripes, disposed according to the rows of scales, which are of a moderately large size; the head, lower fins, and tail, are of a brownish or rosy cast; the dorsal fin, which is deeper and broader than in the rest of the genus, is of a pale violet-colour, crossed by several dusky bars; the adipose fin is very small, and the tail forked. The white fish, very beautiful, and recorded by Mr. Pennant was taken at Ludlow, and measured above half a yard in length, its weight being four pounds eight ounces; the general size of the British specimens being far short of this measure.

The grayling, says Mr. Pennant, is a voracious fish, rising freely to the fly, and will very eagerly take a bait: it is a very swift swimmer, appearing like the transient passage of a shadow, from whence perhaps is derived its name. It is said to be a fish of very quick growth, feeding on water-insects, the smaller kind of testaceae, and the root of other fishes, as well as on the smaller fishes themselves; its stomach is so transverse that large objects cannot be swallowed. It spawns in April and May, the full-grown ova being nearly of the size of peas. The grayling is much esteemed for the delicacy of its flesh, which is white, firm, and of a fine flavour, and is considered as in the highest season in the depth of winter.

SALON, or SALON, in architecture, a very lofty spacious hall, vaulted at top, and sometimes comprising two stories or ranges of windows.

SALO, or SALP. See STARCH.

SALPA, a genus of insects of the order mollusca. Body long, narrow, gelatinous, tubular, and open at each extremity; intestines obliquely placed. The animals of this genus are of a white, transparent hue; and often adhere together; they swim with great facility, and possess the power of contracting and opening at pleasure. There are two divisions: A is furnished with an appendage or tube which differs in different species; B without the terminal appendage.

SALSOULA, salvwort, kali, &c. a genus of
the class and order pentadactyla dignus, and in the natural method ranking under the 12th order, holocercus. The calyx is pentaphylly; there is no corolla; the capsule is monospermous, with a screwed seel. The species are 31, of which the principal are:

1. Salvia kalt grows naturally in the salt marshes of various parts of England. It is an annual plant, which rises above five or six inches high, sending out many side branches, which spread on every side, with short awl-shaped leaves, which are fleshy, and terminate in acute spines.

2. Salvia roscacea grows naturally in Tartary. This is an annual plant, whose stalks are herbaceous, and seldom rise more than five or six inches high.

3. Salvia soda rises with herbaceous stalks near three feet high, spreading wide. The leaves on the principal stalk, and those on the lower part of the branches, are long, slender, and have no spines; those on the upper part of the stalk and branches are longer and thicker. All the sorts of glass-ware are sometimes promiscuously used for making soda or mineral alkali, but this species is esteemed best. The manner of making it is as follows: Having dug a trench near the sea-shore, they plant laths across it, on which they lay the herbs in heaps, and, having made a fire below, the liquor which runs out of the herbs drops to the bottom, which at length thickening, becomes soda, which is partly of alkali, partly of an ash-colour, very sharp and corrosive, and of a saltish taste. This, when thoroughly hardened, becomes like a stone, and in that state is transported to different countries for the making of glass, soap, &c.

4. Salvia tragus grows naturally on the sandy shores of the south of France, Spain, and Italy. This is also an annual plant, which sends out many diffused stalks, with linear leaves an inch long, ending with sharp spines.

5. Salvia verniculata grows naturally in Spain. This has shrubby perennial stalks, which rise three or four feet high, sending out many side branches, with fleshy, oval, acute-pointed leaves, and appear in clusters from the side of the branches; they are hoary, and have stiff prickles. See Soda.

SALT, common. The preparation of that kind of salt which is used for culinary and economical purposes (sulphate of soda) depends upon the well-known fact, that the salt contained in the sea-water, or brine-springs, being a fixed body, will not rise with the vapour of the water. All, therefore, that is wanted, is to expose any water containing salt to evaporation. The salt commonly known by the name of brine-salt is obtained from the water of the sea by evaporation. This evaporation is in some places performed by the heat of the sun, the water being let into shallow basins, in order to expose as large a surface as possible. This method is practiced in the southern provinces of France, and on a very large scale near Aveiro in Portugal. In the northern countries, where the heat of the sun is not sufficiently great, artificial fires are employed. In some salt-works these two methods are united; and in England, and countries where salt-rock is plentiful, that substance is dissolved in salt-water, and then evaporated. In very cold countries another method is employed to separate the salt from sea-water. The water is exposed in trenches on the sea-shore, where it forms a thin stratum, that the cold of the atmosphere acts powerfully in condensing it. As the water is brine, and that part consists of more water, the fluid which remains is consequently more concentrated. The operation is then completed by means of artificial heat.

The most convenient works for making salt from brine by boiling are constructed in the following manner: The salt-pan, or boiling-house, is erected near the sea-shore, and is furnished with a furnace and one or two large pans, which are commonly made of iron plates, joined together with nails, and the joints filled with a strong cement; and the bottom of the pans is prevented from breaking down, by being supported by strong iron bars.

The salt-pan being filled with sea-water, a strong fire of pit-coal is lighted in the furnace; and, then, for a pan which contains about 1400 gallons, the salt-boiler takes the white of three eggs, and incorporates them with the same amount of sea-water, which he pours into the salt-pan, while the water contained therein is only lukewarm, and mixes this with the rest by stirring it about with a rake. In many places they use instead of eggs, the blood of sheep or oxen to clarify the sea-water: and in Scotland they do not give themselves the trouble to clarify it at all. As the water heats, there arises a black frothy scum upon it, which is to be taken off with wooden skimmers. After this the water appears perfectly clear, and by boiling it briskly about four hours, a pan loaded in the common way, that is, about fifteen inches deep, will begin to form crystals upon its surface. The pan is then filled up a second time with fresh sea-water; and about the time when it is half-filled, the scratch-pans are taken out and emptied of a white powder, seeming a kind of curculious earth, which consists of mixture of sea-water, during its boiling, before the salt begins to shoot. When these have been emptied, they are again put into their places, where they are afterwards filled again. This process may be repeated, and by the boiling liquor, does not subside till it comes to the corners of the pan, where the motion of the mass is smaller, and it there falls into these pans placed on purpose to receive it.

The second filling of the pan is boiled down after clarifying in the same manner as the first, and so a third and a fourth; but in the evaporation of the fourth, when the crystals begin to form themselves, they stick the fire, and stay behind the liquor simmering; and in this heat they keep it all the while that the salt is granulating, which is nine or ten hours. The granules, or crystals, all fall to the bottom of the pan; and when the water is almost all evaporated, and the salt lies nearly dry at the bottom, they rake it all together into a long heap on one side of the pan, where it lies a while to drain from the brine, and then is put into barrows, and carried to the storehouse, and delivered in the form of blocks. In this manner the whole process is usually performed in 24 hours, the salt being commonly drawn out every morning. This is the method in most of our salt-works; but in some they fill the pan seven times before they boil up the salt, and so take it out but once in two days, or five times in a fortnight. In the common way of four boilings, from a pan of the usual size, containing 1500 gallons, they may draw from from fifteen to not much more of water every day, each bushel weighing fifty-six pounds.

When the salt is carried into the storehouse, it is put into bracs, which are partitions, like stalls for horses, lined on three sides, and the bottom with boards, and having a sliding-board on the foreside to draw up on occasion. The bottoms are made shelving, being highest at the back, and gradually inclining toward the front by this means the brine remaining among the salt, easily separates and runs from it, and the salt in three or four days becomes sufficiently dry; in some places they use cribs and barrows, which are long and close wicker-baskets, for this purpose; and in some places wooden troughs, with holes in the bottom. The same liquor which remains from the making of salt is what is called bittern, from which Epsom salt or magnesia is often extracted.

Much of the salt obtained from the brine of salt-springs, pits, &c. is white salt. White salt is prepared from sea-water, or any other kind of salt-water, first heightened into a strong brine by the heat of the sun, the evaporation of the air. It may also be prepared from a strong brine, or lixivium, drawn from earths, stones, or sands, strongly impregnated with common salt. Refined rock-salt is that obtained by dissolving fossil or rock-salt in sea-water, and afterwards boiling the solution.

A great quantity of rock-salt is used at Northwich, in order to strengthen their brine-springs; and a much greater quantity is sent coastwise to Liverpool, and other places, where it is either used for strengthening brine-springs or sea-water; much of this rock-salt was formerly exported to Holland, and is still sent to Ireland for the same purposes.

The Northwich rock-salt is never used at our tables in its crude state: and its application to the pickling or curing of flesh or fish, or preserving any provisions, without its being reduced into a refined state, by boiling it without its being dissolved in water, and boiled down in what is called white-salt, is prohibited under a penalty of £5, for every pound of rock-salt so applied. The pure transparent masses, however, of rock-salt, might probably be used by us with our food, without any sort of danger or inconvenience; at least we know that rock-salt is so used, without being refined, both in Poland and in Spain.

The quantity of rock-salt which may be dissolved in a definite quantity, suppose a pint of 16 avoirdupois ounces of water, is differently estimated by different authors. Broom is of opinion that 16 ounces of water will not dissolve quite five ounces of rock-salt; Spielmann thinks that they will dissolve 65 ounces; Newman agrees with Spielmann; Eller says, that seven ounces of fossil rock-salt dissolve in 16 ounces of water; lastly, Hoffman says that 16 ounces of water will not dissolve above six ounces of common salt. It is not wholly improbable, that different sorts of rock-salt may differ somewhat with respect to their solubility in water.
If it is admitted, that 16 ounces of water
to dissolve six ounces of salt and no more,
then we may be certain, that no brine-spring in
any part of the world, can yield six ounces of
salt from a pint of its water. For brine-
springs are, ordinarily, nothing but water in
which fossil salt has been dissolved; but a pint
of the strongest brine cannot contain so
much salt as is contained in a pint of water,
which has been subjected to six ounces of
salt; for a pint of water, in which six ounces
of salt have been dissolved, is increased a little
in bulk; it will do more than fill a pint-
measure, and the salt left in the surplus will
shew how much the salt contained in a pint
of the strongest brine falls short of six ounces.

Of or we may consider the matter in the fol-
lowing manner, which will perhaps be more
intelligible; 16 ounces of water, impregnated
with six ounces of salt, constitute a saturated
brine, weighing 22 ounces; if therefore we
would know how much salt is contained in 16
ounces of such brine, by the rule of propor-
tion we may argue, that if 22 ounces of brine
contain 16 ounces of salt, 16 ounces of
brine will contain \( \frac{16}{22} \times 16 \) ounces of salt. Hence
we may infer, that the strongest brine-springs
will not yield much above one quarter of their
weight of salt.

There are a great many brine-springs in
Cheshire, Worcestershire, Staffordshire,
Hampshire, and in other parts of Great Brit-
ain; some of which are sufficiently rich in
salt to be wrought with profit, others not.
From what has been before advanced, the
reader will readily comprehend that 16 tons
of the strongest brine consist of 12 tons of
water, and of four tons of salt; and, that, in
order to obtain these four tons of salt, the
12 tons of water must be, by some means or
other, evaporated, so as to leave the salt in a
concrete form. Suppose there should be a
brine, which in 16 tons should contain 12 tons
of salt, and only one ton of salt; yet it may
chance, that such a weak brine may be
wrought with more profit than the strongest;
for the proportion of brine to salt, depends as
much upon the price of the salt used in boiling it, as upon the
quantity of salt which it yields. Thus the sea-
water, which surrounds the coasts of Great Britain, may hold salt even more than one-
third, or less than one-fifth part of com-
mon salt; but fuel is so cheap at Newcastle,
that they can evaporate thirty or forty tons
of water, in order to obtain one ton of salt,
and yet gain as much clear profit as those do,
who, in countries less favourably situated for
fuel, boil down the strongest brine.

The advantage resulting from strengthen-
ing weak brine or sea-water, by means of
rock-salt, is very obvious. Suppose that the
sea-water at Liverpool, where large quanti-
ties of rock-salt are refined, would yield one
ton of salt from 48 tons of water; then must
a quantity of fuel sufficient to evaporate 47
tons of water be used, in order to obtain one
ton of salt. But if as much rock-salt is put into
the forty-eight tons of sea-water; as is occasion-
edly dissolved in it, then will the sea-water re-
solve a brine fully saturated, each 16 tons
of which will give four tons of salt, and the
whole of which will be produced by the evaporation
of 47 tons of water will be 12 tons of salt.

SALTS. The word salt was originally con-
ceived to muriat of soda, or common salt, a
substance which has been known, and is
commonly used, from the remotest ages. It
was afterwards generally used by chemists, and
employed by them in a very extensive and
not entirely inconstant sense. Every body which
is capable of dissolving common salt in water,
and not combustible, has been called a salt.

Salts, were considered by the older che-
mists as a class of bodies intermediate be-
tween earths and water. Many disputes arose about what bodies ought to be con-
sidecred under this class, and what ought to
be excluded from it. Acids and alkalies
were allowed by all to be salts; but the dif-
culty was to determine concerning earths
and metals; for several of the earths possess
all the properties which have been ascribed to
alkalis; and the metals are capable of enter-
ning into combinations which possess saline
properties.

In process of time, however, the term salt
was restricted to those classes of bodies, viz.
acids, alkalies, and the compounds which
acids form with alkalies, earths, and metallic
oxides. The first two of these classes were
usually called simply salts, and the bodies
belonging to the third class were called compounds or neutral
salts. This last appellation originated from an
opinion entertained by chemists that acids
and alkalies, of which they are composed,
were of a dissimilar nature, and that they con-
tinued one another; so that the resulting
compounds possessed neither the properties
of acids nor of alkalies, but properties inter-
mediate between the two.

Chiefly by restricting the term salt still more, by tacitly excluding acids and
alkalies from the class of salts altogether. At
present, then, it denotes only the compounds
formed by the combination of acids with
alkalies, earths, and metallic oxides.

No part of chemistry has been cultivated
with more zeal than the salts, especially for
those last 40 years. During that time the
number of saline bodies has been enormously
increased, and a very great number have been determined with precision.

Still, however, this wide and important
region is far from being completely explored.

Chemists have agreed to denominate the
salts of each other by names. The earth, alkali, and metallic oxide, combined
with that acid, is called the base of the salt.

Thus common salt being a compound of
muriatic acid and soda, is called a muriat; and
soda, is called the base of common salt.

Now since there are 32 acids and 37 bases, it would appear, at first sight, that there are 1824
salts; but of the 45 metallic oxides at pres-
ent known, there are a considerable number
which cannot combine with many of the
acids. This is the case also with silica, and
perhaps with some of the other earths. We
must therefore subtract all these from the
full number 1824. To compensate, however,
this deficiency, at least in part, there are se-
veral acids capable of combining with two
bases at once. Thus the tannic acid com-
bines at once with potas and soda. Such
combinations are called triple salts, and they increase the number of salts considerably.

There are some salts, too, which are capable
of combining with an additional dose of their
acid, and others which combine with an addi-
tional dose of their base. The French
chemists denote the first of these combinations by adding to the usual name of the salt the
phrase with excess of acid, or by prefixing it
to the word acidoism; they denote the sec-
dard by prefixing the phrase with excess of
base. This method of naming has the merit
of being precise, but it is exceedingly
labouriously tedious.

The ingenious method of naming saline combinations proposed by Dr. Pearson ought certainly
to be preferred. It is equally precise, if not
more so, and far more convenient in every
respect. It consists in prefixing to the usual
name of the salt, the preposition super, to de-
ote an excess of acid, and the preposition
sub to denote an excess of base. Thus
superplut of potass denotes the salt in its state of
perfect neutralization, without any excess either
crider of the sulphuric acid or of the potass;
supersubplut of potass is the same salt with an
excess of acid; and subsubplut of potass is the
same salt with excess of base.

These three great kinds must increase the number of
salts that we can possibly name; but the
precise number of salts is not known, as many
of them remain still unexamined by chemists. Probably they are not much fewer
than 2000. Some idea may be formed of the
number of saline combinations which have been
made, by recollecting that 40 years ago not
more than 30 salts in all were known.

Of these 2000, however, a considerable
number may be considered as still unknown,
that they have been merely formed without
being examined. Of those which are known,
the greater number have not been applied to
any use, and therefore do not deserve a very
particular description.

As the different genres of salts are denom-
inated from their acids, it is evident that
there are as many genera as there are acids.
The terminations of the names of these ge-
nera differ according to the nature of the
acids which constitute them. When that acid
contains a maximum of oxygen, the termina-
tion of the genus is -ite; when it does not
contain a maximum of oxygen, the termina-
tion of the genus is -ic.

Thus the salts which contain sulphurous acid are called sulphates;
those which contain sulphuric acid are
called sulphides. The formation of some con-
sideration, because the salts differ very
much, according as the acid is saturated with
oxygen or not. The -ates are seldom perma-
ent; when exposed to the air, they usually
convert oxygen, and are converted into -ates.

Every particular species of salt is distin-
guished by subjoining to the generic term
the name of its base. Thus the salt composed
of sulphuric acid and soda is called sulphat
of soda.

Triple salts are distinguished by sub-
joining the name of the salt, and these terms
connected by hyphens. Thus the compound of tar-
tratic acid, potas, and soda, is called trarut of
potassium-the-soda.

The salts then naturally divide themselves
into two grand classes; the first of which
comprehends the alkaline and earthy salts,
which derive their most important characters
from their acids; the second comprehends the
metalline salts, whose bases on the con-
trary stamp their most important properties.

Salts, or the combinations of alkalies with acids which exist in our mineral kingdom, constitute the following genera and species:

Genus I. Potass.

sp. 1. Nitrat of potass.
S A L

Genus II. Soda.

Genus III. Ammonia.

Genus I. Salts of potash.

Sp. 1. Nitrat of potassa. This salt is found native, mixed with nitrat of lime, muriat of potash, and other impurities, encrusting the surface of the earth in different parts of India, the Cape of Good Hope, Peru, Spain, Molletta, &c. It is most commonly in fine cubic crystals. Sometimes, though rarely, massive, or in six-sided prisms.

Its primitive form is a rectangular octahedron. It occurs sometimes in that form, but more frequently the apexes of the pyramids are truncated. But its most usual variety is a six-sided prism, terminated by six-sided pyramids. A specimen of native nitrate from Molletta, analysed by Klaproth, contained

44.55 nitrat of potash
23.43 sulphat of lime
30.40 carbonat of lime
0.20 muriat of potass

100.0

Genus II. Salts of soda.

Sp. 1. Carbonat of soda. This salt is found in Egypt on the surface of the earth, and on the margin of certain lakes which become dry during the summer. It has often the appearance of a rough dusty powder, of a grey colour and alkaline taste. It occurs in China, where it is called Kien; near Tripoli, where it is denominated trons; and likewise in Hungary, Syria, Persia, and India.

It is said sometimes to have been observed in crystals. The primitive form is a rhombohedral octahedron; but the pyramids are usually truncated.

A specimen of this salt from Egypt was found by Klaproth to consist of

32.60 dry carbonat of soda
20.0 dry sulphat of soda
13.0 dry muriat of soda
31.6 water

100.0

A specimen of fibrous carbonat from the interior of Africa, yielded the same chemist

37.0 soda
38.0 carbonic acid
22.5 water
2.5 sulphat of soda

100.0

Sp. 2. Sulphat of soda. This salt is found in Austria, Hungary, Styria, Switzerland, and Siberia; always in the neighbourhood of a mineral spring. It occurs usually in the state of powder, sometimes massive, and even crystallized. Colour greyish, or yellowish white.

A specimen of the monogynia order, in the tetragyna class of plants. The calyx is quadripartite; the corolla is monospermous; and the seed covered with an anulus or loose coat. There are three species, herbs of China.

SALVAGE MONEY, a reward allowed by the civil and statute law for the saving of ships or goods from the danger of the seas, pirates, or enemies.

Where any ship is in danger of being stranded, or driven on shore, justices of the peace are to command the constables to assemble as many persons as are necessary to preserve it; and on its being preserved by their means, the persons assisting therein shall in thirty days after be paid a reasonable reward for the salvage, otherwise the ship or goods shall remain in the custody of the officers of the customs as a security for the same.

SALVIA, sage, a genus of the monogynia order, in the digynia class of plants, and in the natural method ranking under the 43d order, daisieae. The calyx is quinquepartite; the corolla quinquepartite; the berry trisperminous. The species are only five, and the most remarkable are,

1. The officinal, or common large sage, which is cultivated in gardens, of which there are the following varieties: 1. The common sage. 2. The wormwood sage. 3. The green sage with a variegated leaf. 4. The red sage. 5. The red sage with a variegated leaf. These are accidental variations, and therefore are not enumerated as species. The common sage grows naturally in the southern parts of Europe, but is here cultivated in gardens for its leaves, and the variety with red or blackish leaves is the most common in the British gardens; and the wormwood sage is in greater plenty here than the common green-leaved sage, which is lost in few gardens.

2. The tomentosa, generally titled balassic sage by the gardeners. The stalks of this do not grow so upright as those of the common sage; they are hairy, and divide into several branches; the flowers are of a pale blue, about the size of those of the common sort. This sage is preferred to all the others for making tea.

3. The auriculata, common sage of virtue, which is also well known in the gardens and markets. The leaves of this are narrower than those of the common sort; they are hoary, and some of them are indented on their edges towards the base, which indentures have the appearance of ears.

4. The pomerina, with spear-shaped oval leaves, grows naturally in Crete.

5. and 6. The cocinea and formosa, are beautiful hot-house plants, with scarlet flowers.

All the sorts of sage may be propagated by seeds, if they can be procured; but, as some of them do not perfect their seeds in this country, and most of the sorts, but especially the common kinds for use, are easily propagated by slips, it is not worth while to raise them from seeds.

SAMARA, a genus of the monogynia order, in the tetragyna class of plants. The calyx is quadripartite; the corolla is monospermous; and the seed covered with an anulus or loose coat. There are three species, herds of China.

SAMARITANS, an antient sect among the Jews, still subsisting in some parts of the Levant, under the same name.

SAMBUCUS, elder, a genus of the trigyna order, in the pentadactyle class of plants, and in the natural method ranking under the 43d order, daisieae. The calyx is quinquepartite; the corolla quinquepartite; the berry trisperminous. The species are only five, and the most remarkable are,

1. The nigra, or common black elder, with a tree-stem, branching numerously into a large spreading head, twenty or thirty feet high, and large five-parted umbels of white flowers towards the ends of the branches, succeeded by bunches of black and other different-coloured berries, in the varieties; which are, common black-berried elder-tree, white-berried elder, green-berried elder, laciniated elder, and the foliages much laciniate, so as to resemble parsley-leaves, gold-striped-leaved elder, silver-striped elder, silver-dusted elder.

2. The racemos, racemose red-berried elder. This is a resident of the mountainous parts of the south of Europe, and is retained in our gardens as a flowering shrub, having
peculiar singularity in its oval-clustered flowers and berries.

3. The Canadensis, or Canada shrubby elder.

SAMIERS, the Arabian name of a hot wind, peculiar to the desert of Arabia. It blows over the desert in the months of July and August from the north-west quarter, and sometimes it accompanies with all its violence to the very gates of Bagdad, but never affects any body within the walls. Some years it does not blow at all, and in others it appears six, eight, or ten times, but seldom continues more than a few minutes at a time. It often passes with the apparent quickness of lightning. The Arabian and Persians, who are acquainted with the appearance of the sky, or near the time this wind rises, have warning of its approach by a thick haze, which appears like a cloud of dust arising out of the horizon; and they immediately upon this appearance throw themselves with their faces to the ground, and continue in that position till the wind is passed, which frequently happens almost instantaneously; but if, on the contrary, they are not careful or brisk enough to take this precaution, which is sometimes the case, they are certain to feel the full force of the wind, it is instant death.

The above method is the only one which they take to avoid the effects of this fatal blast; and when it is over, they get up and look round; and if they see any one lying motionless, they take hold of an arm or leg, pull and jerk it with some force; and if the limb thus agitated separates from the body, it is a certain sign that the other arm or leg will follow. If, on the contrary, the arm or leg does not come away, it is a sure sign there is life remaining, although to every outward appearance the person is dead; and in that case they immediately cover him or her with clothes, and administer some warm diluting liquor to cause a perspiration, which is certainly but slowly brought about.

The Arabs themselves can say little or nothing of the sandhur; but the stories current among them are, that it always leaves behind it a very strong sulphureous smell, and that the air at these times is quite clear, except about the horizon, in the north-west quarter, before observed, which was then warming it self, to support vegetables, &c. For earth alone, we find it, liable to coalesce, and gather into a hard coherent mass. Common sand is, therefore, a very good addition, by way of manure, to soil upon which it lies, and makes them more open and loose. The best sand for the farmer's use is that which is washed by rains from roads or hills, or that which is taken from the beds of rivers; the common sand that is dug in pits never answers so well. However, if mixed with dung, it is much better than laid on alone; and a very fine manure is made by covering the bottom of sheep-folds with several loads of sand and dry weeds, which are to be taken away, and laid on cold stiff lands, impregnated as they are with the dung and the urine of the sheep.

The sea-sand, used as manure in different parts of the kingdom, is of three kinds: that about Plymouth, and on other of the southern coasts, is of a blue-grey colour, like ashes, which is probably owing to the shells or mussels, and other fish of that or the like colour, being brought by the waves in abundance and in quantity. Westward, near the Land's-end, the sea-sand is very white, and about the isles of Scilly it is very glistening, with small particles of fale; on the coasts of the North Sea the sand is yellowish, brown, or reddish, and contains to great a quantity of fragments of cockleshells, that it seems to be chiefly composed of them. That sea-sand is accounted best which is of a reddish colour; the next in value to this is the bluish; and the white is the worst of all. Sea-sand is best kept up the water, or from sand-banks which are covered by every tide. The small-grained sand is most sudden in its operation, and is therefore best for the tenant who is only to take three or four crops; but the coarse or larger-grained sand is much better for the landlord, as the good it does lasts many years. See HUSBANDRY.

SAND-BAGS, in the art of war, are bags filled with earth or sand, holding each about a cubic foot. Their use is to raise parapets in haste, or to repair what is beaten down.

SAND-REEL, See AMMODYTES.

SANDARACH, in natural history, a very beautiful native fossil, though too often confounded with the common fictitious red sand, which under the name of red sand is much more extensively used. Though with respect to colour it has the advantage of cinnamon while in the mass, it is vastly inferior to it when both are reduced to powders. It is moderately hard, and remarkably brittle; and when exposed to a moderate heat, melts and flows like oil. If set on fire, it burns very briskly.

It is found in Saxony and Bohemia, in the copper and silver mines, and is sold to the merchants with the red sand, at a double price; but its virtues or qualities in medicine are no more ascertained at this time than those of the yellow orent.
There is only one species, viz. the indicum, a tree of Africa and the East Indies.

SANGUIFICATION. See Physiology.

SANGUINARIA, blood-root, is a genus of the monogynia order, in the polystachia class of plants, and in the natural method ranking under the 43d order, umbelicate. This plant has a peculiar sap or blood, which is known as tinctura sanguinis. This tincture is used in medicine, particularly for fevers, and is known as tinctura sanguinis.

SANDIUM, in natural history, the name of a genus of fossils of the class of the scallop, but neither of the rhomboidal nor common kinds, nor any other way distinguishable by its external figure, being made up of several flat plates.

SANTALUM, a genus of the monogynia order, in the octandria class of plants, and in the natural method ranking with those of which the order is doubtful. The calyx is superior; the corolla monopetalous; the stamens placed in the tube; the stigma is simple; the fruit a berry.

The santalum, sanders or sandal wood, grows to the size of a walnut-tree. Its leaves are entire, oval, and placed opposite to each other. Its wood is white in the circumference, and yellow in the centre, when the tree is old. It is said to be a substitute for the timber of the oak, which is inferior to it. In the Hindoos, Persians, and Turks, anoint their bodies. It is likewise burnt in their houses, and yields a fragrant and wholesome smell. The greatest quantity of this wood, to which a sharp and strong perfume is ascribed, remains in India. The red sanders, though in less estimation, and less generally used, is sent by preference to Europe. This is the produce of a different tree, which is common on the coast of Coreomand. Some travellers found it with the wood of Calicut, which is used in dyeing.

The santalum album, or white sanders, is brought from the East Indies in billets about the size of man's hands, leaves, and wood, of a white-ashen, or yellowish colour. It is that part of the yellow sanders wood which lies next the bark. Great part of it, as met with in the shops, has no smell or taste, nor any sensible quality that can recommend it to the physician.

The santalum flavum, or yellow sanders, is the interior part of the wood of the same tree which furnishes the former, is of a pale yellowish colour, of a pleasant smell, and a bitterish aromatic taste, accompanied with an agreeable kind of pungency. This elegant wood might undoubtedly be applied to valuable medical purposes, though at present very rarely used. Distilled with water, it becomes a most delicious and agreeable beverage, in the cold into the consistence of a balsam. Digested in pure spirit, it imparts a rich yellow tincture; which being comminuted to distillation, the spirit arises without bringing over any thing considerable of the flavour of the sanders. The residue contains the virtues of six times its weight of the wood. Hoffmann looks upon this extract as a medicine of similar virtues to ambergris; and recommends it as an excellent restorative in great debilities.

SANTOLINA, lavender-cotton, a genus of the order of polygonum aquales, in the symphytina class of plants, and in the natural method ranking under the 43d order, umbelicate. The umbels are close together, almost in a round head; the fruit is scarious; the flowers of the disk abortive. There are three species. The European is found in many parts of both Scotland and England. This plant was long celebrated for its healing virtues both internal and external; but it is now totally disregarded.

SAPIUM, in natural history, the name of a genus of forest plants, of the class of the monogynia, but neither of the rhomboidal nor common kinds, nor any other way distinguishable by its external figure, being made up of several flat plates.

SAP, or SAPF, in the art of war, is the digging up of the earth of which the garrison, in order to open a covered passage into the moat. It is only a deep trench, covered at top with boards, hurdles, earth, sand-bags, &c. and is usually begun five or six fathoms from the lowest angle of the garrison. See FORTIFICATION.

SAP-COLOURS, a name given to various expressed juices of a viscid nature, which are inspissated by slow evaporation for the use of medicine. See sap green, gamboge, &c.

SAPINDUS, the soapberry tree, a genus of the trigynia order, in the octandria class of plants, and in the natural method ranking under the 23d order, tribulata. The calyx is tetraphyllous; the petals four; the capsules are fleshy, coniate, and ventricose.

The species are 13. of which the most noted are, the saponaria, spinus, trifoliata, and clinemia. The saponaria, with winged leaves, is cultivated as a美化 in the gardens of the West ladies, where it rises with a wood, and grows from 20 to 30 feet high, sending out many branches with winged leaves composed of several pairs of spear-shaped lobes. The flowers are produced all the year round, and at the end of the branches; they are small and white, and make no great appearance. These are succeeded by oval berries as large as mudding cherries, sometimes single, at others, two, three, or four are joined together; these have a sapaneous skin or cover, which closes a very smooth roundish nut of the same form, of a shining black when ripe. The skin or pulp which surrounds the nuts is used to make a soap. The inner part is washed down in fine pulp; but it is very apt to burn and destroy it if often used, being of a very acrid nature.

These plants are propagated by seeds, and kept in the stove.

SAPONARIA, soapwort, a genus of the digynia order, in the decandria class of plants, and in the natural method ranking under the 22d order, carpoxylyl. The calyx is monophyllous and naked; there are five unguiliferous petals; the capsule is oboval and unilocular.

There are nine species, the officinale, vaccaria, carotica, portulaca, illyrica, occynoides, orientalis, huta, and belladonatia. The officinale, which is a British plant, has a creeping
not, so that in a short time it would fill a large space of ground. The stalks are above two feet high, and of a purplish colour. The flowers are white and have five petals, the leaves opposite; they sustain four, five, or more purple flowers each, which have generally two small leaves placed under them. The stalk is also terminated by a loose bunch of small flowers. They are succeeded by oval capsules, with one cell, filled with small seeds. The decoctions of this plant are used to cleanse and scour woollen cloths: the poor people in some countries use it instead of soap for washing; from which use it had its name.

SAPPHIRE, a genus of precious stones, of a blue colour, and the hardest of all except the ruby and diamond. They are found in the same countries with the ruby; also in Bohemia, Alsace, Siberia, and Auvergne. M. de Peyron mentions one found at Augurge, which appeared quite green or blue according to the position in which it was viewed. Cronsstedt, however, informs us, that the blue flower spars are frequently met with under the same name of sapphires; and it is certain from Pliny, b. 37. chap. 9. that the sapphire of the ancients was our lapis lazuli. They are seldom found of a deep-blue colour throughout, or free from some tinge of green; and when they are but slightly tinged, they are named white sapphires. The late unfortunate King of France had one with a stripe of fine yellow topaz in the middle. Some are found half green and half red, and are foliated like the ruby. The fine hard sapphires, called by the jewellers oriental, are of the same nature with the ruby and topaz, excepting the mere circumstance of colour. They are commonly in two oblong hexagon pyramids, joined at their base, and pointed at top; sometimes also in hexagonal columns.

The specific gravity of these precious stones, according to Bergman, is from 3.650 to 3.940. According to others, the specific gravity of all sapphires is 3.994; that of the Brasilian 3.1307; and of those from Puy in Auvergne, 4.0709. When powdered, they are fusible with borax or microcosmic salt, into a transparent glass; and the sapphire, when treated with them, is called magnesia alba. They are said to lose their colour by fire, and to become so hard and transparent as sometimes to pass for diamonds; but Mr. Achard found this to be a mistake, and that the true sapphires are not in the least altered either in colour, hardness, or weight, by the most intense fire. Those of Puy in Auvergne, however, though by their colour and hardness they seem to approach the oriental sapphires, lose both their colour and transparency in the fire, becoming black, and even vitrifying; which plainly shows them to be of a different kind. See Corundum.

SARABANDE, a dance said to be originally derived from the Saracens. According to some authors, it had its appellation from a comedian named Sarabandi, who first introduced it in France. The tune of the sarabande is written in 2 or 3, and its character is both expressive and majestic. One of its distinguishing features is the lengthening the second note of the measure, which at once gives a gravity and consequence to the movement.

SARACA, a genus of the hexandria order, in the diaphysal class of plants. There is no calyx; the corolla is funnel-shaped and quadridi; the filaments are on each side the throat of the corolla; the legumen is pedicellated. There is one species, a tree of the East Indies.

SARCASM, in rhetoric, a keen bitter expression, which has the true point of satire, by which the orator woofs and invades his enemy: such was that of the Jews to our Saviour, "He saved others, himself he cannot save.

SARCOCELE. See Surgery.

SARCOCOLL, a vegetable substance that possesses the following properties:

1. Solid, semi-transparent bodies; usually having a tinge of yellow; taste sweet, but having an impression of bitterness. Dissolves in the mouth like sugar.

2. Equally soluble in water and alcohol; solution yellow. The watery solution has the appearance of mucilage, and may be used for the same purposes.

3. Cannot be digested by the action of alcohol.

4. When heated, softens, but does not melt. It emits a slight smell of clove. When strongly heated, it blackens, and assumes the consistence of tar, emitting a white smoke having an acrid smell.

In a strong fire it scarcely leaves any residue.

These properties shew that sarccoll is a substance intermediate between sugar and gum, possessing some of the properties of each, but certainly approaching nearer to sugar than to gum. How far the combination of sugar and the bitter principle would resemble sarccoll, has not been tried. The following three species may be referred to sarccoll.

1. Common sarccoll. This substance is usually sold in the state of oblong globules from the size of a pea to that of a particle of sand. It is colorless; but sulphur or liquor aloes has imparted to it a semitransparenrency and much of the appearance of gum arabic. But some of the grains are reddish-brown. Its smell is peculiar, and not unlike that of aniseed. When carefully examined, and treated with alcohol, it may be detected: the first, and by far the most abundant, is pure sarccoll; the second consists of small woody fibres, and a soft yellowish-white substance, not unlike the covering of the seeds of some of the crucifom plants; the third is a reddish-brown substance apparently earthy; and the fourth is only detected when the sarccoll is dissolved in water or alcohol. It then appears in soft transparent tumulous masses like jelly.

The pure sarccoll amounts to 0.8 of the whole. When the sarccoll is dissolved in alcohol or water, and obtained again by evaporation, it loses its smell. It then assumes the form of semitransparent brittle brown cakes very like gum.

Sarccoll exudes spontaneously from the penna sarccolla; a shrub which is said by botanical writers to be indigenous in the north-eastern parts of Africa. The disease under which it is known concerning the way in which it exudes is known as "sarsollia".

SARDONYX, a precious stone consisting of a mixture of the chalcedony and carnelian, sometimes in strata, but at other times blended together. It is found 1. Stripped with the skin, which may be cut in cameo as well as the onyx. 2. White with red deutetical figures, greatly resembling the mocha-stone; but with this difference, that the figures of one, are of a red colour, in the other black. There is no real difference, excepting in the circumstance of hardness, between the onyx, carnelian, chalcedony, sardonyx and agate, notwithstanding the different names attributed upon them. Mongers informs us, that the yellow, or orange-coloured agates, with a wary or undulating surface, are now commonly called sardonyx.

SARMENTOSA. See Surmontum, a long shoot like that of a vine, the name of the 11th class in Linnaeus's Fragments of a Natural Method, consisting of plants which have climbing stems and branches, that, like the vine, attach themselves to the bodies in their neighbourhood for the purpose of support. See Botany.

SARTHRA, a genus of the trigynia order, in the pentandria class of plants, and in the natural method ranking under the 20th order, and the 2nd class; the genus is pentapetalous; the capsule unilocular, trivalved, and coloured. There is one species, an annual of Virginia.

SARPLAR of wool, a quantity of wool, once called a pocket or half-sack; a sack containing 80 tod; a tod two stone; and a stone 14 pounds. In Scotland it is called sarpilath, and contains 80 stone.

SARRACENIA, side-saddle plant, a genus of the monogynia class, in the polyandria class of plants, and in the natural method ranking under the 54th order, miscellaneous. The corolla is pentapetalous; the calyx is double, and triphylous below, pentaphylous above; the capsule quinquelocular; the style has a stigma of the form of a shield. There are five species, herbs of North America.

SARSAVRILLA. See Smilax.

SASH, a mark of distinction, which in the British service is generally made of crimson silk for the officers, and of crimson mixed with white cotton for the sergeants. It is worn in the same shape, but of course undistinguishable from that worn by the soldiers of the line, and is sewed on the shoulder. Sashes were originally invented for the convenience and ease of wounded officers, &c. by means of which, in case any of them were so badly wounded as to render them incapable of remaining at their posts, they might be carried off with the assistance of two men. They are now reduced to a very small size, and of course unfit for the original purpose. Both the sash and gorget, indeed, must be considered as mere marks of distinction, to point out officers on duty. In some instances they are worn together; in others, the gorget is in laid aside, and the sash only worn. The British cavalry tie the sash on the right, the infantry on the left, side. The sashes for the imperial army are made of crimson and gold, for the Prussian army black silk and silver, and for the Portuguese crimson silk with blue tassels. The modern French have their sashes made of three colours, viz, white, pink, and light-blue, to correspond with the national flag.
SAT

SASSAFRAS, the wood of an American tree. See Laurels. It is said to be warm, aromatic, and frequently employed as an infusion, in the way of tea, is a very pleasant drink: its oil is very fragrant, and possesses most of the virtues of the wood.

SATELLITE. See Astronomy.

SATRAPA, or SATRAPS, in Persian antiquity, described, ordered, and more commonly by the governor of a province.

SATURATION, like most other technical terms introduced into chemistry before the science had acquired much precision, has been used with a great deal of latitude, being sometimes taken in one sense and sometimes in another. But in order to be understood, it is necessary to use the word with some degree of precision.

If we make the attempt, we shall find that water will not dissolve any quantity of salt that we please. At the temperature of 0° F., it dissolves only 0.354 parts of its weight of salt; and if more salt than this is added, it remains in the water undisolved. When water has dissolved as much salt as possible, it is said to be saturated with salt, and that sense is at least analogous to the original meaning of the word. Whenever, then, a substance A refuses to combine with an additional quantity of another body B, we may say that it is saturated with B. It takes place whenever the affinity of the water and salt, is balanced by the cohesion of the particles of the salt, and therefore indicates that these two forces are equal.

In the same manner, water, after having absorbed a certain quantity of carbonic acid gas, refuses to absorb any more. We may indeed pass carbonic acid gas through water in this state, but it makes its escape unaltered. Water which refuses to absorb carbonic acid gas is saturated with that acid.

This saturation takes place when the affinity between the gas and the water is balanced by the elasticity of the gas, and indicates of course that these two forces are equal.

In the two instances the saturation is occasioned by opposite causes. The salt refuses to dissolve in the water when the cohesion of its particles equals its affinity for the water; the carbonic acid gas, when the elasticity of its particles equals its affinity for water. In the first case, it is the attractive force of cohesion which opposes further solution; in the second case, it is the repulsive force of elasticity. Hence the different method which must be followed to diminish these forces, and enable the water to dissolve a greater proportion of these respective bodies. Heat, by diminishing the force of cohesion, enables water to dissolve a greater proportion of the saline bodies. Accordingly we find that in most cases hot water dissolves more salt than cold water. Common salt is almost the only exception to this general law. On the other hand, cold, by diminishing the elasticity, or at least the expansibility of gasous bodies, enables water to dissolve a greater proportion of these bodies. Thus the colder the water is, the greater a proportion of carbonic acid is dissolved; the point of freezing of water limits this increase of solubility, because at that point the cohesive force of the particles of water becomes so great as to cause them to cohere, to the exclusion of those bodies with which they were formerly combined. Hence the reason, that most bodies separate from water when it freezes. But they generally retard the freezing considerably, by opposing with all the strength of their affinity the cohesion of the water; this is, that the freezing point of water, when it holds bodies in solution, is lower than the freezing point of pure water. A table of the freezing points of different saline solutions would be a pretty accurate indication of the affinity of the different salts for water: for the affinity of each salt is of course proportional to the degree of cold at which it separates from the water, that is, to the freezing point of the solution. In this sense of the word saturation, which is certainly the only one that it ought to bear, it may be said with propriety that there are certain bodies which cannot be saturated by others. Thus water is capable of combining with any quantity whatsoever of sulphuric acid, nitric acid, and alcohol; and all bodies seem capable of combining with almost any quantity whatsoever of water. Several of the metals, too, are capable of combining with any quantity of water which they hold in solution. In general, it may be said that those bodies called solvents are capable of combining in any quantity with the substances which they hold in solution. Thus water may be added in any quantity, however great, to the acids, and to the greater number of salts.

If we take a given quantity of sulphuric acid diluted with water, and add to it slowly the solution of soda by little at a time, and continue the mixture to the point of saturation, we shall find that for a considerable time it will exhibit the properties of an acid, reddening vegetable, and having a taste perceptibly sour; but these acid properties gradually diminish after every additional of the alkaline solution, and at last disappear altogether. If we still continue to add the soda, the mixture gradually acquires alkaline properties, converting vegetable blues to green, and manifesting a urine like of a new kind of vegetable. These properties become stronger and stronger the greater the quantity of the soda which is added. Thus it appears that when sulphuric acid and soda are mixed together, the properties either of one or the other predominate according to the proportions of each; but that there are certain proportions, according to which when they are combined, they mutually destroy or disguise the properties of each other, so that neither predominates, or rather, so that both disappear.

When substances thus mutually disguise each other's properties, they are said to neutralize one another. This property is common to a great number of substances; it manifests itself most strongly, and was first observed, in the acids, alkalies, and earths. Hence the salts which are combinations of these different bodies received long ago the name of neutral salts. When bodies are combined in the proper proportion which produces neutralization, they are often said to be saturated; but in this case the term is used improperly. It would be much better to confine the word to properties, and to introduce the term neutralization to denote the state in which the peculiar, properties of the component parts mutually disappear; for very frequently neutralization and saturation by no means coincide. Thus in tartrate of potash the acid and alkali neutralize each other; yet it cannot be said that the potash is saturated; for it is still capable of combining with more tartarious acid, and of forming superparticite of potash, a compound in which the ingredients do not neutralize each other; for the salt has manifestly a preponderance of the properties of the acid.

SATUREIA, SAVOURY, a genus of the gymnospedia order, in the didynamia class of plants, and in the natural method ranking under the 42d order, verticillate. The segments of the corolla are nearly equal; the stamina standing asunder. There are eight species; the most notable are: 1. The bot-tens, or summer savoury, is an annual plant, which grows naturally in the south of France and Italy, but is cultivated in this country both for the kitchen and medicinal uses. 2. The montana, or winter savoury, a perennial plant, grows naturally in the south of France and Italy, but is cultivated in gardens both for culinary and medicinal purposes. Both kinds are propagated by seeds. Summer savoury is a very warm and aromatic herb, and affords in distillation with water a subtle essential oil, of a penetrating smell, and very hot acid taste. It yields little of its virtues by infusion to aqueous liquors; rectified spirit extracts the whole of its taste and smell, and elevates nothing in distillation.

SATURN. See Astronomy.

SATYR, or SATIRE. See Poetry.

SATYRIUM, a genus of the diandria order, in the gynandria class of plants; and in the natural method ranking under the 42d order, verticillate. The nectarium is scrofula, or inflamed double behind the flower. There are 21 species.

SAUCISSON, in fortification, a mass of large branches of trees bound together; and differing only from a fascine, as this is composed of small branches of twigs.

SAU. See ZUMBEUS.

SAVIOUR, Order of St. a religious order in the Romish church, founded by St. Bridget, about the year 1345; and so called from its being pretended that our Saviour himself appointed to the foundess its constitutions and rules. According to the constitutions, this order is principally founded for religious women who pay a particular honour to the holy virgin, but there are some monks of the order, to administer the sacraments, and spiritual assistance to the nuns. The number of nuns is fixed at sixty in each monastery; and that of the religious priests at thirteen, according to the number of the apostles, of whom St. Paul was the thirteenth. There are also four deacons, representing the four doctors of the church, St. Ambrose, St. Augustine, St. Gregory, and St. Jerome; and eight lay-brothers; who altogether make up the number of the thirteen apostles, and the seventy-two disciples of Jesus Christ. The nuns are not admitted till eighteen years of age, nor the friars before twenty-five; and they at least perform a year's novitiate.

SAUNDERS. See SANTALUM.

SAURURUS, a genus of the tetragnaria order, in the heptandra class of plants; and in the natural method ranking under the second order, pipiperata. The calyx is a calyx, with unifolious scales; there is no corolla;
there are four genuine, and four monomorphous berries. There is one species, a herb of Vitex.  

SAUVAGESIA, a genus of the Monogynia order, in the pentadita class of plants; and in the natural method ranking with those of the Grecian type, the Delphinium of the corolla is pentametabolous and fringed; the calyx is ovate; the nectar is nectariferous; the thalamus the same, having its leaves placed alternately with the petals; the capsicum unilocular. There is one species, a native of St. Domingo; and  

SAW, an instrument which serves to cut into pieces several solid matters; as wood, stone, ivory, etc. The best saws are of tempered steel ground bright and smooth; those of iron are only hammer-hardened: hence, the first, besides their lower stiffer, are likewise found smoother than the last. They are known to be well hammered by the stiff bending of the blade; and to be well and evenly ground, by their bending equally in a bow. The edge in which the teeth is always thicker than the back, because the back is to follow the edge. The teeth are cut and sharpened with a triangular file, the blade of the saw being first fixed in a whet stone, and have been in the teeth are set, that is, turned out of the right line, that they may make the kerf or fissure the wider, that the back may follow the better. The teeth are always set for coarse cutting if they are hard; because the ranker the teeth are set, the more stuff is lost in the kerf. The saws by which marble and other stones are cut, have no teeth; these are generally very large, and are stretched out and held even by a frame. The lapidaries, too, have their saws, as well as the workmen in mosaic; but of all mechanisms, none have so many saws as the joiners, and these are as follows: The pit-saw, which is a large two-handed saw, used to saw timber in pits; this is chiefly used by the sawyers. The whip-saw, which is also two-handed, used in sawing such large pieces of stone, as saws will not easily reach. The hand-saw, which is made for a single man's use, of which there are various kinds; as the bow, or frame saw, which is furnished with checks; by the twisted cords which pass from the ends of these checks, and the tongue in the middle of them, the upper ends are drawn closer together, and the lower set further apart. The tenon-saw, which being very thin, has a back to keep it from bending. The compass-saw, which is very small, and its teeth usually not set; its use is to cut a round, or any other compass-kerf: hence the edge is made broad, and the back thin, that it may have a compass to turn in.  

SAWING. In early periods, the trunks of trees were split with wedges into as many and as thin pieces as possible; and if it was necessary to have them still thinner, they were heaved on both sides to the proper size. This simple and wasteful manner of making boards has been still continued in some places, to the present time. Peter the Great of Russia endeavoured to put a stop to it, by forbidding heave boards to be transported across the river Neva. The saw, however, though so convenient and beneficial, has not been able to banish entirely the practice of splitting timber used in building, or in making furniture and utensils, for we do not speak here of fire-wood; and, in fact, it must be allowed that this method is attended with peculiar advantages, which at all events, one can never possess. The wood-splitters perform their work more expeditiously than sawyers, and split timber is much stronger than that which has been sawn; for the sinew, or a portion of the wood, and  

SAW, two-footed tools. The piece of wood which is to be sawn through is secured by cramps. The saw with which the grain is at work has a perfect resemblance to our frame-saw. It consists of a square frame, having in the middle a blade, the teeth of which are set alternately on the plane of the frame. The piece of wood which is to be saw  

Saw extends beyond the end of the bench, and one of the workmen appears standing, and the other sitting on the ground. The saws, in which the blade is fastened, have the same form as that given to them at present. In the bench are seen holes, in which the cramps that hold the timber are stuck. They are shaped like the figure 7; and the ends of them reach below the boards that form the top of it.  

The most beneficial and ingenious improvement of this instrument was, without doubt, the invention of saw-mills, which are driven either by water or by the wind. Mills of this kind have been in use as early as the fourteenth century, in Germany, on the small river Roer or Ruier; for though Ausonius speaks properly of water-mills for cutting stone, and not timber, it cannot be doubted that they were used as mills for manufacturing deals, or that both kinds were erected at the same time. The art, however, of cutting marble with a saw is very old. Pliny co-jectures that it was invented by Carus; at least, he knew no building incrusted with marble of greater antiquity than the palace of king Mausolus, at Halicarnassus. This edifice is celebrated by Vitruvius, for the beauty of its marble; and Pliny gives an account of a sieve used for cutting it; for it is the sand properly, say, and not the saw, which produces that effect. The latter presses down the former, and rubs it against the marble; and the coarser the sand is, the longer will be the time required to polish the marble which has been cut by it. Stones of the soup-rock kind, which are indeed softer than marble, and which would require less force than wood, were sawn at an early period. For the far harder and glassy kinds of stone were sawn then also; for we are told of the discovery of a building which was encrusted with cut agate, carnelian, lapis lazuli, and amethysts. We have, however, found records of any of the Greek or Roman writers of a mill for sawing wood; and as the writers of modern times speak of saw-mills as new and uncommon, it would seem that the oldest construction of them has been forgotten; or, that some important improvement has made them appear entirely new.  

Becker says, with his usual confidence, that saws were invented in the 17th century. In this he erred, for when the infant Henry sent settlers to the island of Madeira, which was discovered in 1420, and caused European fruits of every kind to be carried thither, he ordered saw-mills to be erected also, for the purpose of sawing into deals the various species of excellent timber with which the island abounded, and which were afterwards transported to Portugal. About the year 1450, the city of Breslau had a saw-mill, which was raised on the rent of three marks; and in 1490 the magistrates of Erfurt purchased a forest, in which they caused a saw-mill to be erected, and they rented another mill in the neighbourhood besides.
Norway, which is covered with forests, had the first saw-mill about the year 1530. The mode of making the timber was called the new art; and because the exportation of deals was by these means increased, that circumstance gave occasion to the deal-trade, introduced by Christen III. in the year 1545. Soon after Henry VIII. of England, having taken possession of the island of Jersey from Mary queen of England to the court of Rome, having seen a saw-mill in the neighborhood of Lyons, the writer of his travels thought it worthy of a particular description. In the sixteenth century, however, there were mills with different saw-blades, by which a plank could be cut into several deals at the same time. The first saw-mill was erected in Holland at Saardam, in the year 1560; and the invention of it is ascribed to Cornelis Cornelissen. Perhaps he was the first person who built a saw-mill at that place, which is a village of great trade, and has still a great many saw-mills, though the number of them is being daily less, for within the last thirty years a hundred have been given up. The first mill of this kind in Sweden was erected in the year 1633. At present, that kingdom possesses the largest perhaps ever constructed in Europe, at Linkoping, and twelve feet broad, drives at the same time seventy-two saws.

In England saw-mills had at first the same fate that printing had in Turkey, the ribbon-loom in the dominions of the church, and the crane at Strasburgh. When attempts were made to introduce them, they were violently opposed, because it was apprehended that the sawyers would be deprived by them of their means of getting a subsistence. For this reason, it was found necessary to abandon a saw-mill erected by a Dutchman near London, in 1603; and in the year 1700, when Hooghten laid before the nation the advantages of such a mill, he expressed his apprehension that it might excite the rage of the people and have dangerous consequences. It was the case in 1676 or 1678, when an opulent timber-merchant, by the desire and approbation of the Society of Arts, caused a saw-mill, driven by wind, to be erected at Limehouse, under the direction of James Stanfield, who had learned, in Holland and Norway, the art of constructing and manning machines of that kind. A mob assembled, and pulled the mill to pieces; but the damage was made good by the nation, and some of the rioters were punished. A new mill was afterwards erected, which was suffered to work without molestation, and which gave occasion to the erection of others. It happens, however, that this was still the case in the kingdom of England; for one driven also by wind had been built at Leith, in Scotland, some years before.

The mechanism of a sawing-mill may be reduced to three principal things: the first, that the saw is drawn up and down as long as is necessary, and returned in the same manner, by water to the wheel; the second, that the piece of timber to be cut into boards is advanced by an uniform motion to receive the strokes of the saw; for here the wood is to meet the saw, and not the saw to follow the wood, therefore the motion of the wood and that of the saw ought immediately to depend on the one on the other: the third, that when the saw has cut through the whole length of the piece, the whole machine stops itself, as is done by a brake, if not having an obstacle to surmount, the force of the water should turn the wheel with too great rapidity, and break some part of the machine.

The upper part of Plate Saw-mill, &c. represents the circular saw-mill introduced by Mr. Goeree, in England, in 1555. For giving it a place, we have erected it at Orundoor-wharf, Westminster-bridge. ABD, fig. 1, is a strong bench, similar to those used by carpenters. In the middle of this, is an opening through which the saw F comes. The saws I, figs. 1 and 2, is a circular plate of steel, with teeth like those of a large pit-saw on its circumference, and a round hole in the middle of it, through which the spindle E, fig. 2, of the saw passes. The saws are fastened to it, by a lever C fixed to the spindle E, and another, f, which slips on the spindle, and is pressed against the saw by a nut b, screwed on the end of the spindle, so as to hold the saw tight between the flanges, when the eccentric part is taken off to be sharpened, and another put in its place in a very short time. The ends of the spindle are brought to points, which work in small holes in the wooden eagle, fig. 3, which is seen at d, f; the other screw is put through a piece of wood P, supported by the two uprights GG, and can be raised or lowered at pleasure by wedges, so as to bring the plane of the saw exact in right angle with the surface of the bench: the saw is turned round with a great velocity by a strap passing round the rigant H and the whee I, which receives its motion from a horse-wheel.

The piece of wood to be sawed is guided by a straight bar K, which is always made to move parallel to the plane of the saw by two iron coupling-rods h, so that it can be set at any distance from the saw, according to the width of the piece to be cut, and held there by screws.

The machine before us is chiefly used for ripping up three-inch deal planks. The bar K is set the proper distance from the saw, and screwed fast. The workman takes the plank, and laying its edge against the bar K,above it, endways against the saw, which, as it turns, cuts the wood with surprising quickness.

SANIFRAGA, sawfrage, a genus of the digynia order, in the decandria class of plants; and in the natural method ranking under the 13th order, succulentes. The calyx is quinqupartite; the corolla pentapetalous; the capsule bistratiisecta, unicorial, and polypermumous.

There are 50 species, of which the most remarkable are 1. The granulata, or white sawfrage, which grows naturally in the meadows in many parts of England. The roots of this plant are like grains of corn, of a reddish colour without: there is a variety of this with double flowers, which is very ornamental. The leaves are tongue-shaped, gathered into heads, rounded at their points, and have catillagious and sawed borders. The stalk rises two feet and a half high, branching out near the ground, forming a natural pyramid to the top. The flowers have five white wedge-shaped petals, and ten stamens, placed circularly the length of the tube, terminated by roundish purple summits. When these plants are strong, they produce very large pyramids of flowers. 2. The un-yes, or none-say, grows naturally on the Alps, and also in great plenty on a mountain of Ireland, called Mangerton, in the county of Kerry, in that island. The roots of this are perennials. The opposite leaf grows naturally on the Alps, Pyrenees, and Helvetic mountains: it is also found pretty plentifully growing on Ingeborough hill, in Yorkshire; Snowdon, in Wales; and some other places, from there what plant, with stalks trading upon the ground. The flowers are produced at the end of the branches, of a deep blue.

SAY, or Save, in commerce, a kind of serge, or woven stuff, much used abroad for the making of the said variety of cloths: with us it is used for aprons by several sorts of artificers, being usually dyed green.

SCABBARD, to, to punish with the scabbard of a bayonet. Soldiers are sometimes scabbarded, under the sanction of the captain of companies, for slight offenses committed among themselves. A court-martial is held in the serjeant's room or tent, to ascertain the culprit's guilt; it having been previously led to him to abide by the judgment of his comrades, in this manner, or to be tried by a regimental court-martial.

The word scabbard has been sometimes used in a figurative sense, to distinguish those persons who have obtained rank and promotion in the army without seeing much hard service, or in the service of companies, or slight officers.

SCABIOSA, scabiosa, a genus of the monogynia order, in the tetricandria class of plants; and in the natural method ranking under the 15th order, succulentes. The common calyx is polyphyllous; the proper one is double, superior; the receptacle is paleaceous or naked. There are 42 species. The most remarkable are 1. The renunci, or scabious, grows naturally in many places of Britain. The flowers are produced upon naked footstalks at the ends of the branches; they are of a purple colour, and have a faint scent. 2. The sucissa, or devil's bit, grows naturally in woods and moist places. This has a short tap-root, the end of which appears as if it was bitten or cut off, whence the plant has taken its name. Both these have long been recommended as aperient, sudorific, and expectorant; but the present practice has no dependence on them.

SCAVOLA, a genus of the monogynia order, in the pentandria class of plants. The corolla is monopetalous; the tube slit longitudinally; the border quinqupartite and lateral. The fruit is a prism inferior and monoomalous; the nucleus bicolar. There are three species.

SCALE. See Anatomy, Ear.

SCALDS, in the history of literature,
name given by the ancient inhabitants of the northern countries to their poets, in whose writings their history is recorded.

SCALE, a mathematical instrument, consisting of several lines drawn on wood, brass, silver, &c. and variously divided, according to the purposes it is intended to serve; whence it acquires various denominations, as the plain scale, diagonal scale, plotting scale, Gunter's scale, &c. See INSTRUMENTS, Mathematical.

SCALE, in music (from the Latin, scala), the denominations issued to the arrangement made by Guido, of the six syllables, ut, re, mi, fa, sol, la: also called gamut. This order of sounds, to which the French have added that of si, bears the name of scale, i.e. ladder, because it represents a kind of ladder, by means of which the voice or instrument rises to acute, and descends to grave; each of the seven syllables being, in a manner, one step of the ladder.

The word scale is also used to signify a series of sounds rising or falling from any given point; or, to the greatest possible distance, through such intermediate degrees as make the succession most agreeable and perfect, and in which we have all the harmonious divisions most commodiously divided. This scale is properly called the universal system, as including all the particular systems.

This enumeration of all the diatonic sounds of our system, ranged in order, and which we call the scale, was designated by the Greeks as a tetrachord, because, in effect, their scale was composed of only four sounds, which they repeated from tetrachord to tetrachord, as we repeat ours from octave to octave.

SCALÆNE Triangle. See Geometry.

SCALENUS, in anatomy. See Neck.

SCALES of fish. See Fish, Vol. 1, p. 924, 3d col.

SCAMMONY, in the materia medica. See Convolvulus, and Gum Resins.

SCANDALUM MAGNATUM, is the special name of a stately, and also of a worm, done to any high personage of the land, as prelates, dukes, marquises, earls, barons, and other nobles; and also the chancellor, treasurer, clerk of the privy seal, steward of the house, justice of one bench or other, and other great officers of the realm, by false news, or horrible or false messages, whereby debates and discord, betwixt them and the commons, or any scandal to their persons, might arise. 2 R. II. c. 5. This statute has given name to a writ, granted to recover damages thereupon. Cowell.—It is now clearly agreed, that though there are no express words in the statute which give an action, yet the party injured may maintain one on this principle of law; that when a statute prohibits the doing of a thing, which, if done, might be prejudicial to another, in such case he may have an action on that very statute for his damage. 2 Mod. 122.

SCANDIX, cheril, shepherd's needle, or earvus's comb, a genus of the digynia order, in the pentandria class of plants; and in the natural method ranking under the 45th order, umbellate. The corolla is radiating; the stamens united; the petals emarginated; the flrets of the disc frequently male. There are eleven species. The most remarkable is the odorata, with angular crowded seeds. It is a native of Germany; and has a very thick perennial root, composed of many fibres, of a sweet aromatic taste, like asafoetide, from which come forth many large leaves, which branch out into those of fern, whence it is named sweet fern.

SCAPEMENT, a general term for the manner of communicating the impulse of the wheels to the pendulum of a clock. Common scapements consist of a conical wheel and pallets of iron. See Clock-work.

SCAPOLITE, a mineral found at Arendal, in Norway. It is of a pearl colour, and is crystallized in long, four-sided, rectangular prisms. Faces longitudinally streaked. Its specific gravity is 3.08, and it is hard enough to scratch glass. Fracture foliated in two directions. Before the blowpipe, it froths and melts into white enamel. It is composed of 45 silica; 30 alumina; 14 iron oxide; 2 water.

SCAPULÆ. See Anatomy.

SCAPULAR. See Anatomy.

SCARABÆUS, beetle, a genus of insects of the order coleoptera. The generic character is antennae or horns claveate, with a fissile tip; legs generally toothed; body thick and compact. This genus is extremely extensive, there being nearly one hundred species. Among these the most remarkable is 1. the scarabaeus Hercules, or Hercules beetle, which sometimes measures not less than five, or even six inches in length: the wing-shells are of a smooth surface, of a blueish or brownish grey colour, sometimes nearly black, and commonly marked with several small, round, deep-black spots, of different sizes: the head and limbs are coal-black; from the upper part of the breast or thorax proceeds a horn or process of enormous length, in proportion to the body: it is sharp at the tip, where it curves slightly downwards, and is marked beneath by two or three denticulations, and furnished throughout its whole length with a fine, short, velvet-like pile, of a brownish orange-colour: from the front of the head proceeds also a strong horn, about two-thirds the length of the former, toothed on its upper face, but not furnished with any of the velvet-like pile which appears on the former. This species is a native of several parts of South America, where great numbers are said to be sometimes seen on the called mammas, rapping off the rind of the slender branches by working nimbly round them with the horns, till they cause the juice to flow, which they drink in intoxication, and thus fall senseless from the tree: however, as the learned Fabricius has well observed, seems not very probable; since the thoracic horn, being bearded on its lover surface, would undoubtedly be made bare by this operation. This species, from the large size of all its parts, affords an admirable example of the characters of the genus. It varies much in size, and it may even be doubted whether some of the smaller specimens have not been occasionally regarded by authors as distinct species. The female is destitute of both of the frontal and thoracic horn, but in other points resembles the male. See Plate Nat. Hist. fig. 352.

2. Scarabæus Goliath, the Goliath beetle, is highly remarkable both in point of size and colour; it is larger in body than the preceding, and its head and thorax, marked with longitudinal black stripes or variegations, and purple-long-wing-shafts: the head is divided in front into two forked processes: the limbs are black, and very strong. It is a native of Africa. A supposed variety sometimes occurs, in which both the thorax and wing-shafts are of a pale yellowish brown instead of rose-colour, and are marked with black variegations.

3. Scarabæus melolontha, cockchafer, is one of the most common European beetles. This insect is extremely familiar in our own Island, the larva or caterpillar inhabiting ploughed lands, and feeding on the corn, &c. This beautiful insect makes its appearance during the middle and the decline of summer. The cockchafer sometimes appears in such prodigious numbers as almost to strip the trees of their foliage, and to produce immense injury to those of the locust tribe. It appears from a paper by Mr. Molinex, printed in the Philosophical Transactions for the year 1697, that some particular districts in Ireland were overrun by this insect in a wonderful manner; and the failure of the wheat in the year 1804 has been by some attributed to the numbers of the larva of this insect which were lodged in the earth.

The larva, or caterpillar, of this insect, is said to be two, and sometimes three years, in passing from its first form into that of the perfect insect. The eggs are laid in small detached heaps beneath the surface of some cold, and the young, when first hatched, are scarcely more than the eighth of an inch in length, gradually advancing in their growth, and occasionally shifting their skins, till they arrive at the length of near two inches. At this period they begin to prepare for their change to the one, to the other, or to the pupa, selecting for the purpose some small clod of earth, in which they form an oval cavity, and, after a certain space, direct themselves of their last skin, and immediately appear in the chrysalis form, which, during the succeeding summer, when the beetle emerges from its retirement, and commits its depredations on the leaves of trees, &c. breeds, and deposits its eggs in a favourable situation, after which its life is very short duration.

4. A much more elegant insect of this kind is the scarabæus fulvus, or variegated beetle. It is nearly twice the size of the cockchafer, and of an elegant chestnut-colour, with the wing-shafts beautifully marked with white variegations. It is common in many parts of Europe, but extremely rare in England. See Plate Nat. Hist. fig. 351.

5. A species of peculiar beauty, is the golden beetle, scarabæus auratus; it is about the size of the common or black garden beetle, but of a somewhat flatter shape; and of the most brilliant, varnished, golden-green colour, with the wing-shafts varied towards the lower part by a few slight, transparent, white streaks. This beautiful species is not uncommon during the hottest part of
summer, frequenting various plants and flowers; its larva or caterpillar is commonly found in the hollows of old trees, or among the loose dry soil at their roots, and sometimes in the earth of orchards. It remains about three weeks on the plant, while it increases in size; it clings to a paper or chrysalis, out of which the insect emerges in a short time afterwards.

This may be sufficient for a general idea of the Linnaean genus scarabaeus. It may be added that the species are extremely numerous, and one of the great charms of the family is the singular appearance of the males in many kinds; that even the most romantic imagination can hardly conceive a structure of horn or process which is not exquisitely wrought in some of the tribe. See Plate Nat. Hist. fig. 353.

SCARIFICATION, in surgery, the operation of making several incisions in the skin by means of lancets, or other instruments, particularly the cupping-instrument.

SCARLET, a beautiful bright red. See Dyeing.

SCARUS, a genus of fishes of the order cichlidae. The generic character is, jaw bones, divided in the middle, crested on the edge; the teeth conical and conglomerate. There are 15 species. The most remarkable are, 1. Scarus Crenatus, Crenate scarus. General length about 12 inches; body broad, sloping, scales extremely large, lateral line running on every scale over which it passes. Native of the Mediterranean, and particularly about the coasts of Crete, but is also found in the Indian sea.

2. Scarus rivulatus, rivulated scarus. Native of the Red Sea, observed by Forskal; said to arrive at a great size; scales very small; dorsal and anal fin occasionally reunion in a channel; tail forked; supposed to feed principally on the different kinds of fish, and considered as an edible fish; but said to be sometimes productive of disagreeable symptoms from the wounds inflicted by the sharp rays of its dorsal fin.

3. Scarus purpuratus, purplish scarus, an elegant specimen, is said to be in Italy applied to the laborious ably lacerate: the purple stripes on the body terminated at their upper edges of the fin, and marked at the tip by a large lunate, marginal, black spot; distinguished and analyzed towards the base by a purple stripe; ventral fins blue: tail marked with longitudinal purple spots, and on each side by a purple stripe; shape slightly rounded; lateral line unmarked; scales lax, in the mullet. Native of the Arabian seas, observed by Forskal.

SCAVAGE, a toll or custom antiently exacted by mayors, sheriffs, and bailiffs, of cities and towns-corporate, and of merchant-strangers, for wares imported and other goods taken to scale without the liberties, which was prohibited by 19 Hen. VII. But the city of London still retains this custom.

SCAVENGERS, two officers annually chosen in every parish in London and its suburbs, by the churchwardens, constables, and other inhabitants: to hire persons called rakers, with cars, to clean the streets, and carry away the dirt and filth, with the ashes and dust from every house. For which purpose a scavenger's tax is made and levied on all houses, being allowed by the justices of the peace; but it must not exceed 4 K.

SCHELLEFFERIA, a genus of the class and order pentadactyla, of the class crustacea. The calyx is five-toothed; corolla five-petalled; capsula eight or ten celled; seeds solitary, semi-circular. There is one species, of New Zealand.

SCHEMIDELTA, a genus of the digyna order, in the order angrecacea, of the class magnoliflorae. The calyx is diphylleous; the corolla tetraphyllous; the gynoecium achenaceous. Characters: when scratching, the corolla is striped.

SCHEMUSCUS, a genus of the monogynia order, in the order angrecacea, of the class magnoliflorae. The calyx is diphylleous; the corolla monopetalous; the gynoecium stamillifera. There are two species: three-toothed seeds.

SCHEUZERIA, a genus of the tri- gynia order, in the angrecacea, of the class magnoliflorae. The calyx is diphylleous; the corolla is monopetalous; the gynoecium stamilliferous. There are two species, of South America.

SCHELUS, a gen

SCHELUS, a genus of the thistledown order, in the order angrecacea, of the class magnoliflorae. The calyx is diphylleous; the corolla is monopetalous; the gynoecium stamilliferous. There are two species, of South America.
superior; corolla five or six-cleft; stigma two; berry one-seeded. There are two species, parasites of the West Indies.

SCHLEBERRA, a genus of the digynia order, in the pentandria class of plants; and in the natural method ranking under the third of which the order consists. The calyx is quinquepartite; the corolla funnel-shaped, with the filaments in the throat, and having each a scale at the base. There is one species, of the East Indies.

SCHWANTZI, a genus of the class and order didynamia angiopteris. The calyx is four-cleft; the upper lobe very small; the lowest very large and emarginate. There is one species, of North America.

SCHWENKFELDA, a genus of the monogynia order, in the pentandria class of plants; and in the natural method ranking under those that are doubtful. The calyx is quinquelocular; the stigma parted into five; the berry quinquelocular, with a number of seeds. Of this there are two species, 1. Chioneus; 2. Aspera.

S. Hirta. The first two are natives of Guiana, the other of Jamaica. The leaves of all of them are remarkably rough, and stick to the fingers or clothes.

SCHWENKIA, a genus of the monogynia order, in the chasmatia class of plants. The corolla is almost equal, plaited at the throat, and glabrous; there are three bare stamens; the capsule bicalcarata and polyspermous. There is one species.

SCIENA, a genus of fishes of the order the cyclostomi, the generic character is, head small; dorsal fins two, seated in a furrow, into which they may occasionally withdraw; Gill-membrane six-rayed. There are two divisions in this genus, 1. with divided or humated tail; 2. with or rounded tail. There are twenty species. The most remarkable are: 1. Scena cirroa, bearded scena. Habit of that of a carp; length from one to two feet; colour pale yellow, brownish on the sides, and described as each one of many obliquely longitudinal dusky-blue lines, which assume a slightly silvery cast towards the abdomen; upper lip obtuse, and longer than the lower; teeth small; first dorsal fin beginning between the second and third, with a brown stripe: pectoral, ventral, and caudal, dusky; anal red; tail slightly humated: at the base of the gill-covers a black spot, and beneath the chin a short dusky line; native of the Mediterranean and other seas; known to the ancient Greeks and Romans, by whom it was held in considerable estimation as a food.

2. Scena laticlava, scena scena. Habit of a salmon: size considerable, growing, according to some authors, to the length of several feet: colour bluish silvery, with a dusky cast on the back: scales rather small; eyes red; and gill-covers ruffled with a red; tail slightly forked; lateral line nearly straight; native of the Mediterranean and northern seas, and often entering rivers; known to the ancients by the names of Ibraxis and Íbrus, and more recently esteemed as a food, particularly by the Romans.

SCIATICA. See Medicine.

SCILLA, the squill, in botany, a genus of the monogynia order, in the hexadendra class of plants, and in the natural method ranking under the first order, coracridae. The corolla is hexapetalous and deciduous; the filaments filiform. There are 22 species. The most remarkable is the maritime, or sea-onion, whose roots are used in medicine. Of this there are two sorts, one with a red, and the other with a white root; which are supposed to differ little from each other. From the root of the white, and the other of the red, are prepared medicinally. The roots are large, somewhat oval-shaped, composed of many coats lying over each other like onions; and at the bottom come into several parts. From the root of the white the root rise several shining leaves, which continue green all the winter, and decay in the spring. Then the flower-stalk comes out, which rises two feet high, and is naked halfway, terminating in a pyramidal thyrsus of flowers, which are white, composed of six petals, and spread open like the points of a star. This grows naturally on the seashores, and in the ditches where the salt water naturally flows with the tide, in most of the warm parts of Europe, so cannot be propagated in gardens; the frost in winter always destroying the roots, and for want of salt water they do not thrive in summer. The root is very poisonous, and its nauseous, but the acrid and aromatic性质 that it ulcerates the skin if much handled. Taken internally, it powerfully stimulates the solids, and produces urine, sweet, and expectoration. If the dose is not too large, it is not disagreeable to the taste, and has a purgative effect. The principal use of this medicine is where the primar vais are abounded with morbid matter, and the lungs are oppressed by rheumatic phenig.

SCIOPTIC, a sphere, or globe of wood, with a circular bottom, and perforation, wherein a lens is placed. It is so fitted that, like the eye of an animal, it may be turned round every way, to be used in making experiments in a darkened room. See Optics.

SCIRE, FACIAS, is a judicial writ, and properly lies after a year and a day after judgment given; whereby the sheriff is commanded to summon or give notice to the defendant, that he appear and show cause why the plaintiff should not have execution.

SCHIRKEBELI, is a juridical writ, and founded on some state of record, as judgments, recognizances, and letters patent, on which it lies to enforce the execution of, or to vacate their effect; and is a judicial writ of execution, yet it is so far in nature of an original, that the defendant may plead to it, and is in that respect considered as an action; and therefore, it is held, that a release of all actions, or a release of all executions, is a good bar to a scire facias. SeeRol. Abr.

SCRIPUS, a genus of the monogynia order, in the triandria class of plants, and in the natural method ranking under the third part of the order; the flowers are radially symmetrical, simple, and inarticulated all round. There is no corolla, and only one beardless sepal. There are 69 species, springing from the East Indies.

SCRIPHRUS. See Surgery.

SCRIBUS, SQUIREE, a genus of quadrupeds of the same class, and with the same character, is upper front-teeth curved, long, and sharp; grinders in the upper jaw five on each side, in the lower four; claws in the skeleton; tail (in most species) spreading to the sides. The animals composing this elegant genus are remarkable for the liveliness of their disposition, the severity of their motions, and the general beauty and neatness of their appearance. They inhabit woods, live entirely on vegetable food, and take up their residence in the hollows of trees, where they prepare their nests. Some specimens of the species furnishes the skin, reaching from the fore legs to the hind; by the help of which they are enabled to spring to a greater distance than the rest of the genus, and to transport themselves occasionally from tree to tree; but this momentary support in air is all that they are capable of; and though called, from this circumstance, flying squirrels, they are unable to continue that action in the manner of bats. The species of squirrels enumerated in the twelfth edition of the Systema Naturae Linnaeus amounted to no more than eleven; but such has been the spirit of research among modern naturalists, that the number is now increased to near thirty. The most noted are

1. Scurus maximus, great squirrel. Of all the species yet discovered, this is the largest, being equal in size to a cat. It is a native of Asia, and is described by Linnaeus. Mons. Somers, who informs us that it is found in the Malay country, and especially about the mountains of Cardamum, where it feeds on fruits, and is particularly fond of the fruit of the Sophora japonica, which it pierces, when ripe, in order to obtain the liquor. The fur on the whole animal is long and full; the top of the head, ears, back, and sides, are furrugious, and a small band of a crimson color is found on each ear, passing along the neck towards the sides. This animal, according to Somers, is easily tamed, and is called about the coasts of Malabar by the name of the great wood-rat.

See Plate Nat. Hist. Fig. 314.

2. Scorus vulgaris, common squirrel.

The general appearance and manners of this species are so well known that it is unnecessary to particularize them. It is a native of Asia, and is found in all the northern and temperate parts of Asia, but is observed to vary in the cast of its colours in different climates, and in the northern regions becomes grey in winter; it also varies in the size of its ears. A general measure of the European squirrel seems to be about eight inches from nose to tail, and of the tail about seven. In the spring these animals seem peculiarly active, pursuing each other among the trees, and exerting various efforts of agility. During the warm summer nights they may be also observed in a similar exercise. They seem, as Bunton observes, to dread the heat of the sun: for during the day they commonly remain concealed in their nests, making their principal excursions by night. Their habitat is so contrived as to be perfectly clean, warm, and impermeable by rain, and is furnished with moss, dried leaves, &c. and situated between the fork of two branches; it has only a small aperture near the top, which is of a conical form, so as to throw off the rain. The young are generally three or four in number, and are produced about the middle of May, or in May earlier.

The squirrel feeds on the buds and young shoots of trees, and is said to be particularly fond of those of the fir and pine; it also collects great quantities of nuts, which it deposits in the hollows of trees for its winter
food, together with beech-mast, acorns, &c. Dr. Pallas also assures us, that those of Siberia collect various kinds of fungi for this purpose. In a state of captivity, nuts form its principal food, but it will also eat a great variety of fruits and other vegetable substances, and is delighted with sugar and various sweets.

In some parts of Siberia the squirrel is found entirely white, with red eyes. About Lake Biskul it is often entirely black, or black with the belly white; and in some parts of Europe, or particularly in our own, it is occasionally found with the tail milk-white, and all the other parts of the usual colour.

3. Sciurus cinereus, grey squirrel. This species is confined to North America, in many parts of which it is extremely common, and in its general form, as well as in its way of life, resembles the European squirrel. It is a large and elegant animal, being of the size of a half-grown rabbit, and measuring about twelve inches to the tail; different individuals of the same species differ in size. The whole animal is of an elegant pale-grey, with the inside of the ears and the hinder parts of the body white. This animal is said to be found in Carolina, Pennsylvania, and other American districts; though, according to Mr. Pennant, it scarcely extends farther north than New England. Mr. Pennant also allows that it is a native of South as well as North America. In the latter it is in some years so extremely numerous as to do incredible damage to plantations, especially those of maize or Indian corn; for which reason it is one of the proscribed animals about the colonies. This species principally among trees, in the hollows of which it makes its nest, with straw, moss, &c. feeding on acorns, fircones, maize, &c. as well as on fruits of various kinds. It is said to store great quantities of provision for winter, which it deposits in holes which it prepares beneath the roots of trees, &c. It is a difficult animal to kill, changing its place on the trees with such expedition, as generally to elude the shot of the quickest marksman.

4. Sciurus striatus, the striped squirrel, is a native of the northern regions of Asia, and of several of the colder parts of North America; it has also been found, though very rarely, in some parts of Europe, and differs from the major part of the squirrel tribe in its manner of life; which rather resembles that of the dormouse, being chilled in passant to subterraneous retreats or burrows, the apartments of which are filled with various stores of acorns, nuts, grain, &c. collected for winter use. It also resembles some of the marine tribe, in being provided with cheek-pouches, for the temporary reception of food; a particular not to be found in any other species of squirrel. Its general length is about five inches and a half, and of the tail rather more. Its colour on the upper parts is a reddish brown, and on the under white; down the back a broad line runs, and on each side the body are two others; the included space between each being of a pale-yellow tinge.

These animals are, according to the observations of Dr. Pallas, extremely common in Siberia, inhabiting the maple and birch woods of that country, and generally forming their nests or burrows beneath some fallen tree; they are never known to ascend trees in the manner of other squirrels, unless suddenly surprised or pursued, when they climb with great expedition, and conceal themselves in the branches of trees, or collect their stores during the austral season, and on the setting in of winter conceal themselves in their burrows, the entrances of which they stop; and pass the greatest part of the rigorous season in sleep, and in feeding on the~stores thus collected; but if, by an unusual continuance of severe weather, their provisions happen to fail, they then sally out in quest of fresh supplies, and occasionally make their way into granaries, and even into houses. In the choice of their food they are remarkably nice, and have been observed, after filling their pouches with rye, to fling it out on meeting with wheat, and replace it with the superior grain. They are of a wild nature, and are by no means easily reconciled to a state of captivity; continuing timid, and shewing no symptoms of attachment to their owners. They are taken merely on account of their flesh, which is long or short, according to a slight or ordinary fur, have a very pleasing appearance, when properly disposed, and are said to be chiefly sold to the Chinese.

5. Sciurus vulgaris, common flying squirrel. This highly antiquated animal is the only flying squirrel yet discovered in Europe, where it is extremely rare, being found chiefly in the most northern regions, as in Finland, Lapland, &c. It also occurs in the interior districts of India and most parts of Asia; it is far more common, and abounds in the birch and pine woods of Siberia in particular. It appears to have been confounded by authors with the Virginia flying squirrel (S. vulpes), but is a totally distinct species. Its colour on the upper parts is an elegant pale or whitish grey, and on the under parts milk-white. Its general size is inferior to that of a common squirrel, measuring about three inches and a quarter in length, which is shorter than the body, thickly furred of a slightly flattened form, and rounded at the extremity. The flying squirrel generally resides in the hollows of trees towards the part projected; preys on the various mosses. It is a solitary animal, and is only seen in pairs during the breeding-season. It rarely makes its appearance by day, emerging only at the commencement of twilight, when it may be seen climbing about the trees, and darting with great velocity from one to the other. The colour of its upper part so much resembles that of the pale silvery bark of the birch-trees which it frequents, that it is no easy matter to distinguish it, while engaged in climbing about during its evening exercise. It feeds chiefly on the young shoots, buds, and catkins of the birch, as well as on the bark of the trees; in winter it congregates in its nest, coming out only in mild weather; but does not become torpid during that season.

This animal readily springs to the distance of twenty fathoms or more, and by this motion conveys itself from the top of one tree to the middle part of that to which it directs its flight, which is always slightly downwards. It thaws from the top of a tree, immediately begins to climb it with great activity, sometimes elevating, and sometimes depressing its tail. If thrown from the top of a tree, it immediately spreads its membranes, and, balancing itself, endeavouring to raise the extremity of the tail. The young are produced about the beginning of or before the middle of May, and are two, three, and sometimes four, in number; they are as first born, and nearly void of hair, and the parent feeds them by covering them with her flying membrane; leaving her nest only at the approach of evening, and carefully concealing the young with the moss of the nest.

SCLERANTHUS, a genus of the monotypic order, in the dicotyledon class of plants; and in the natural method ranking with those that are doubtful. The calyx is quinquepartite; the corolla bilabiate; the filaments are barren; the capsules free, and joined together, involucrately, with one seed. Of this there is one species, viz. aromatica, a native of Guiana.

SCLERANTHUS, a genus of the monotypic order, in the dicotyledon class of plants; and in the natural method ranking with those that are doubtful. The calyx is quinquepartite; the corolla bilabiate; the filaments are barren; the capsules free, and joined together, involucrately, with one seed. Of this there is one species, viz. aromatica, a native of Guiana.

SCLERANTHUS, a genus of the monotypic order, in the dicotyledon class of plants; and in the natural method ranking with those that are doubtful. Of this there is one species, viz. aromatica, a native of Guiana.
gular but distinct spots of pale brown. Their feelers are thick and fihly, notwithstanding an old English saying, that "a fly's legs, and the legs of a fly, differ much in weight and size; some weighing 37 ounces, others not 22; the length of the largest to the tip of the tail, 25 inches; the breadth, three feet five inches; the bill is seven inches long; the head, neck, and convicts of the wings are of a pale brown; the middle of each feather black; the breast and belly white, marked with narrow oblong black lines; the back is white, spotted with a few black streaks; the quills and feathers are black, but the inner webs spotted with white; the tail is white, tinged with red, and beautifully barred with black; the legs are long, strong, and of a blueish grey colour; the bottoms of the toes flat and broad, to enable it to walk on the soft mud, in search of food.

2. The phoxopus, or whimbrel, is much less frequent on our shores than the curlew; but its haunts, food, and general appearance, are much the same. It is observed to visit the neighbourhood of Spalding (where it is called the curlew knot) in vast flocks in April, but continues there no longer than May, and is seen there any other time of the year; it seems to be peculiar to this place, and its breeding-place. The specific difference in the size, this never exceeding the weight of twelve ounces.

3. The ructica, or woodcock, during summer inhabits Norway, Sweden, Poland Prussia, the march of Brandenburg, and the northern parts of Europe; they all retire from those countries in the beginning of winter, as soon as the frosts commence, which force them into milder climates, where the ground is open, and adapted to their manner of feeding. They live on worms and insects, which they search for with their long bills in soft grounds and moist woods. Woodcocks generally arrive here in flocks, taking advantage of the night or a mist; they soon separate; but, before they return to their native haunts, they pair. They feed and fly by night, beginning their flight in the evening, and returning the same way through the same glades to their day retreat. They leave England the latter end of February, or beginning of March; not but they have been known to continue here accidentally.

4. The gallenago, or common snipe, is well known. Its usual weight is about four ounces. The jack snipe (which is by some thought a different species) does not weigh above half as much.

5. The calidris, or red-shank.

6. The gullis, or green-glass.

7. The aegocephala, or godrot.

SCOLOPENRIDA, CENTPEDEA, a genus of insects of the order apitera: the generic character is, antennae setaceous; body depressed; legs numerous, equalling the number of segments of the body on each side, feelers two, setaceous. The larger species of the genus scolopendra, found only in the hotter regions of the globe, are insects of a formidible appearance, and possess the power of inflicting severe pain and inflammation by their bite. Of these one of the most conspicuous is the scolopendra morsitans, a native of many parts of Asia, Africa, and South America. Its length is sometimes not far short of ten inches; its colour is yellowish brown, the legs and under parts of the body being much paler; the head is armed on each side with two large claws. The genera have the same strong or horny nature as those of the aranea avicularia, but placed in a different direction, the two fangs meeting horizontally when in action; these fangs are furnished with the inside, near the tip, with an oblong slit, through which, during the act of wounding, an acrimonious or poisonous fluid is discharged; the eyes are several in number: on each side the head, and are placed in a small oval group; the legs are on each side the body, and the tail is terminated by a pair of processes, which perfectly resemble the rest of the legs, except that they are larger, andpec the first joints strongly spined or articulated on the inside. These horrible insects are said to be chiefly found in woods, but, like the small European species, they are occasionally seen in houses, and are said to be so common in some particular situations, that it would be quite obliged to place the feet of their beds in vessels of water, in order to prevent their attacks during the night.

2. Scolopendra Plumeri, or Plumer's scolopendra, is a species of a similar genera, or length through the former, sometimes measuring a foot and a half. According to the description and figure of Scolip, the body consists of thirty-two joints, exclusive of the head and tail.

3. Scolopendra galera, or common insect, and is met with in similar situations with the onius asellus and armadillo; it is an animal of swift motion, and is furnished with fifteen legs on each side; its colour is a polished chestnut-brown, somewhat paler beneath, and its usual length an inch and a half. See Plate Niti. Hist. fig. 335.

4. Scolopendra electricis, like the former, an inhabitant of damp situations, and not unfrequently makes its appearance in houses; its general length is about an inch and a half, and its diameter scarcely more than the tenth of an inch, being of an extremely light and slender form, the colour is dusky brown, with the legs yellowish; these are about seventy on each side. The motions of this insect are tortuous and undulatory, seldom continuing long in the same direction; it is possessed of a high degree of phlegm and splendour, which however seems to be only exerted when the animal is pressed or suddenly disturbed, when it discribes a beautiful serpentine line, so powerful as not to be obliterated by two canes on the same table. It is also tenacious of life, remaining seemingly uninjured for a great many days in the closest confinement.

5. Scolopendra subterrana so much resembles the former, that it might be equally confounded with it; it is however of a still more slender form, and of a much paler colour, viz. a light yellow brown; it is found in damp places, and often under ground; it is not peculiar of any phosphoric splendour, nor is it capable of surviving many hours in a state of confinement, unless placed in a very moist situation.

The scolopendra are oviparous animals, and the young, at their first exression, are furnished only with a few feet on each side; acquiring after a certain period, the legitimate number peculiar to their species, of which there are eleven.

SCOLOPIA, a genus of the tetrandria class and order. The calyx is inferior, three or four-parted; corolla three or four-petalled, hermaphrodite, six-seeded; seeds arillate. There is one species, a shrub of Santa Cruz.

SCOLYTHUS, a genus of the class and order tetrads monogyonia. The calyx is two-cleft; corolla one-seeded. There is one species, a shrub of Santa Cruz.

SCOLYMUS, a genus of the polygonia class and order tetrads monogyonia. The calyx is two-cleft; corolla one-seeded.

S. COMBER, Scomber, a genus of fishes of the order thunnacei; the generic character is, body oblong, smooth, sometimes carinated by the lateral line; fins (in most species) above and below, towards the tail. Curlews are frequent in this species, of which the most remarkable are:

1. Scomber scombrus, common marek. This beautiful fish is a native of the European and American seas, generally appearing in shoals, round particular coasts. Its great resort, however, seems to be within the Arctic circle, where it resides in innumerable masses, grows to a larger size than elsewhere, and is considered as one of their favourite food, consisting chiefly of marine insects, in far greater plenty than in warmer latitudes. During the severity of the northern winter it is often observed to lie imbedded in the soft mud, beneath the icy ice of surrounding the polar coasts, being thus sufficiently protected from the effects of frost; and, on the return of spring, is generally believed to migrate in enormous shoals, of many miles in length and breadth, and to visit the coasts of more temperate climates in order to deposit its spawn. Its route has been supposed nearly similar to that of the herring, passing between Iceland and Norway, and proceeding towards the northern part of our own island, where it part throws itself off into the Baltic, while the grand column passes downwards, and enters the Mediterranean through the straits of Gibraltar.

This long migration of the mackerel, as well as of the herring, seems at present to be greatly called in question; and it is thought more probable that the shoals which appear in such abundance round the more temperate European coasts, in reality reside during the winter at no very great distance, numbering themselves in the soft bottom, and remaining in a state of torpidity; from which they are awakened by the warmth of the returning spring, and gradually recover their former activity. At their first appearance their eyes are observed to appear remarkably dim, as covered with a kind of film, which passes off as the season advances, and they appear in their full perfection of colour and vigour.

The shape of the mackerel is highly elegant, and it is justly considered as one of the most beautiful of the European species. Its calyx is a simple cup of food is universally established, and it is one of those fishes which have maintained their reputation through a long succession of ages; having been highly esteemed by the ancients, who prepared from it the particular cautery or sauce known...
The use of the score is indispensable in composition; to the conductor of any performance it is also highly requisite, in order to his knowing whether each performer follows his part, and to enable him to supply any accidental omission with the piano-forte, organ, or other instrument, at which he is not present.

SCORPAEN, a genus of fishes of the order Scorpaenidae, and of the family of the scorpiæna, is distinguished by a peculiar form of the mouth, the head and body being abruptly truncated in front, of vast size, and armed with various protuberances and spines. Among the most common of the European species is the scorpiæna, which is frequently seen in considerable numbers in various parts of the Mediterranean, where it chiefly frequents the shallow areas, lying in ambush among the rocks, despite the many stories of its supposed appearance, its rather formidable structure, and its great size. It is a large fish, with many rows of small sharp teeth; the eyes large; the gill-covers armed with strong spines intermixed with ctenii; the body covered with large, dusky scales, spotted with black on the back, and beneath the tail, with a redish cast; the dorsal fin is furnished with strong spiny rays, the fish, when caught, erects, and this fin is disposed in such a way as to lengthen the body, forming a perpendicular direction; both jaws are armed with numerous small teeth; and the upper jaw is furnished with three cirri, viz., one on each side, and one in the middle. The general colour of this fish is a tawny brown, but when it is moving with much pace. It is a native of the Indian seas, and measures twelve or fifteen inches in length. See Plate Nat. Hist., fig. 357.

4. Scorpiæna scrofa, flying scorpiæna, a fish of this family of peculiar structure, length ten or twelve inches; colour brownish-yellow, variegated by various shades of the same colour; skin dense and tough; head depressed, and furnished with strong teeth on different parts of the mouth; the head is not, however, without some exception, the broader and more robust of the two; it is furnished with a pair of soft spines, situated on the rump of the fish; the body is covered with large, dusky scales, spotted with black on the back, and beneath the tail, with a redish cast; the dorsal fin is furnished with strong spiny rays, the fish, when caught, erects, and this fin is disposed in such a way as to lengthen the body, forming a perpendicular direction; both jaws are armed with numerous small teeth; and the upper jaw is furnished with three cirri, viz., one on each side, and one in the middle. The general colour of this fish is a tawny brown, but when it is moving with much pace. It is a native of the Indian seas, and measures twelve or fifteen inches in length. See Plate Nat. Hist., fig. 357.

5. Scorpiæna diadactyla, diadactyl scorpiæna. General length about a foot; form extremely grotesque; general colour dusky brown, varied above by transverse yellow streaks, and beneath by roundish spots of the same colour; skin dense and tough; head depressed, and furnished with strong teeth on different parts of the mouth; the head is not, however, without some exception, the broader and more robust of the two; it is furnished with a pair of soft spines, situated on the rump of the fish; the body is covered with large, dusky scales, spotted with black on the back, and beneath the tail, with a redish cast; the dorsal fin is furnished with strong spiny rays, the fish, when caught, erects, and this fin is disposed in such a way as to lengthen the body, forming a perpendicular direction; both jaws are armed with numerous small teeth; and the upper jaw is furnished with three cirri, viz., one on each side, and one in the middle. The general colour of this fish is a tawny brown, but when it is moving with much pace. It is a native of the Indian seas, and measures twelve or fifteen inches in length. See Plate Nat. Hist., fig. 357.

5. Scorpiæna diadactyla, diadactyl scorpiæna. General length about a foot; form extremely grotesque; general colour dusky brown, varied above by transverse yellow streaks, and beneath by roundish spots of the same colour; skin dense and tough; head depressed, and furnished with strong teeth on different parts of the mouth; the head is not, however, without some exception, the broader and more robust of the two; it is furnished with a pair of soft spines, situated on the rump of the fish; the body is covered with large, dusky scales, spotted with black on the back, and beneath the tail, with a redish cast; the dorsal fin is furnished with strong spiny rays, the fish, when caught, erects, and this fin is disposed in such a way as to lengthen the body, forming a perpendicular direction; both jaws are armed with numerous small teeth; and the upper jaw is furnished with three cirri, viz., one on each side, and one in the middle. The general colour of this fish is a tawny brown, but when it is moving with much pace. It is a native of the Indian seas, and measures twelve or fifteen inches in length. See Plate Nat. Hist., fig. 357.
3. The largest and by far the most formidable of the genus is the scorpion of Lannes, or great African scorpion. This species is of so large a size as often to measure from four inches from the head to the beginning of the tail, and four inches if measured from the tip of the claspers to that of the tail. Its colour is a dark brown, inclining to yellow beneath, and in the interstices of the joints and the tips of the spines it is a reddish cast. This species is found in many parts of Africa, where it is held in great dread; the effect of its sting producing very severe symptoms, and sometimes even proving fatal.

The poison of the scorpion is evacuated through two very small oblong foramina situated on each side of the tip of the sting. It is well known that a diversity of opinion has subsisted among authors relative to this particular. The celebrated Rea, assisted by the best microscopes he could procure, was not able to detect any orifice, though he was well convinced of the existence of such, from observing a minute drop of poison exuding from near the tip. Others have denied the existence of any foramen; but Vallisner and Lewenhock have properly described two foramina, viz. one on each side; so that the sting of the scorpion can with greater facility discharge its poisonous fluid than that of any other insect. A third foramen is said to have been sometimes observed.

The part in scorpions which is situated beneath the breast, bearing the appearance of two minute combs, has been fixed upon by Linnaeus as the criterion of the species; the number of teeth, however, varying occasionally in the same species, renders this character uncertain. The use of these organs remains as yet uninvestigated.

Scorpions are venomous insects, producing a very considerable number of young at once; there are at first entirely white, but acquire their dusky colour in the space of a few days. They are observed to cast their skin once in two years, in the manner of spiders. There are 10 species.

SCORPIEO. See Astronomy.

SCORPION, in the ancient art of war, an engine chiefly used in the defence of the walls of fortified places, by throwing arrows, firebricks, or great stones.

Marcellinus describes the scorpion as consisting of two beams bound together by ropes. From the middle of the two, rose a third beam, so disposed, as to be pulled up and let down at pleasure; and on the top of this were fastened iron hooks, where a sling was hung, either of iron or hemp; and under the third beam lay a piece of hair-cloth full of chalk, tied with cords. It had its same scorpion, when the long beam or tiller was erected, it had a sharp top in manner of a sting.

To use the engine, a round stone was put into the sling; and four persons on each side, loosen the beams bound by the ropes, draw back the whole beam to the hook; then the engineer, standing on an eminence, gave a stroke with a hammer on the cord to which the beam was fastened with its hook, which set it at liberty; so that hitting against the soft hair-cloth, it struck out the stone with a great noise.

SCORPIURUS, CATERILLAR, in botany, a genus of the decamorphia order, in the dipteral class of plants; and in the natural method ranking under the 32d order, papilionaceae. The legumin is contracted by incisions on the inside between every two seeds, and revolved round. There are four species; the most remarkable of which is the voninius, a native of Italy and Spain. It is an annual plant, with trailing herbaceous stalks, which at each joint have a spatulate-shaped leaf with a long foot-stalk. From the wings of the leaves there is formed a footstalk of the flowers, which sustain at the top one yellow butterfly-flower, succeeded by a thick twisted pod having the size and appearance of a large catterpillar, whence it had this title. This has long been used for medicinal purposes. It is grown on account of its odd shape than for any great beauty.

SCORZA, a mineral of a green-coloured sand, the specific gravity of which is 3.35. It is found in Transylvania, and is composed of 43.9% silica, 21.00 alumina, 14.00 lime, 16.50 oxide of iron, 0.25 oxide of manganese.

SCORZONERA, Viper's Grass; a genus of the polygonum aquilis order, in the syngenesia class of plants; and in the natural method ranking under the 49th order, composite. The receptacle is naked; the pappus planum; the calyx indurated, with scales imbricated on their margins. There are 29 species; the most remarkable is the hispanica, or common scorzonera, which is cultivated in the gardens of this country, both for culinary and medicinal purposes. The root is carrot-shaped, about the thickness of a finger, covered with a dark-brown skin, is white within, and has a milky juice. The stalk rises three feet high, is smooth, and branching at the top. The flowers are of a bright yellow colour.

SCOTLAND. By 5 Anne c. 8, the union of England and Scotland was effected, and the twenty-five articles of union agreed to by the parliaments of both nations, were ratified and confirmed as follows: viz. the accession to the monarch of Great Britain, shall be the same as was before settled with regard to that of England. The united kingdoms shall be represented by one parliament. There shall be a communication of all rights and privileges between the subjects of both kingdoms, except where it is otherwise agreed. When England raises 2,000,000, by land-tax, Scotland shall raise 48,000l.; the standards of the coin, of weights and measures, shall be reduced to those of England, throughout the united kingdoms. The laws relating to the trade, customs, and the excise, shall be the same in Scotland as in England; but all the other laws of Scotland shall remain in force, though alterable by the parliament of Great Britain; and particularly laws relating to private right are not to be altered, but for the evident utility of the people of Scotland. Sixteen peers are to be chosen to represent the peerage of Scotland in parliament, and forty-five members to sit in the house of commons.

The sixteen peers of Scotland shall have all privileges of parliament, and all peers of Scotland shall be Great Britain, ranking next after those of the same degree at the time of the union, and shall have all privileges of peers, except sitting in the house of lords, and voting on the trial of a peer.

It was formerly resolved by the houses of lords, that a peer of Scotland, claiming and having a right to sit in the British house of peers had no right to vote in the election of the sixteen Scotch peers; but it seems now settled, that a Scotch peer, made a peer of Great Britain, has a right to vote in the election of the sixteen Scotch peers; and that if any of the sixteen Scotch peers are created peers of Great Britain, they thereby cease to sit as representatives of the Scotch peerage, and new Scotch peers must be elected in their room.

SCRIBING, in joinery, &c. is a term used when one side of a piece of stuff is to be fitted to another that is irregular. In order to make these join close all the way they scribe them; they are to be scribed close to the other they intend to scribe to, and opening their compasses to the widest distance these two pieces stand from each other, they bear the point of one of the legs against the side they intend to scribe to, and with the other point draw a line on the stuff to be scribed. Thus they form a line on the irregular piece parallel to the edge of the regular one; and if the stuff is cut exactly to the line, when these pieces are put together they will seem a joint.

SCRIPTURE. All profane scoffing at the holy scripture, or exposing any part thereof to contempt or ridicule, is punishable by fine and imprisonment. 1 Ham. 7.

SCHOPHULARIA, See Medicine.

SCHOPHYLUS, Figwort; a genus of the angiosperma order, in the dianthus class of plants; and in the natural method ranking under the 49th order, composite. The calyx is quinquedent; the corolla almost globular, seven to a flower, very crispate bilocular. There are 22 species, of which the most remarkable are: 1. Nodosus, or the common figwort, which grows in woods and hedges. The leaves have a slight smell and bitter taste. A decoction of them is said to cure hogs of the measles. An omission made in the root was formerly used to cure the piles and scrophulous sores, but is at present out of practice. 2. Aquatica, water-figwort, or butterwort. It grows on the sides of rivulets and other wet places, and has a pellitory smell, though not so strong as the preceding. The leaves are used in medicine as a corrector of senna, and against the side against. 3. Scoroma, or basin-leafed figwort. It grows on the banks of rivulets, &c. in Cornwall. 4. Verpalis, or yellow figwort. It grows in hedges in Surrey.

SCLEROT. See Anatomy.

SCHRUNK, weight equal to the third part of a drachm, or to twenty grains. See Weight.

SCULPTURE. Sculpture is an art, in which, by means of taking away, or adding to, matter, all sorts of figures are formed, either
SCULPTURE.

In clay or wax, wood, marble or other stones, or metal.

The art of sculpture, in its most extensive sense, comprehends not only carving in wood, stone, or marble, but also engraving in all its kinds, and casting in bronze, or lead, wax, and plaster of Paris, as well as modeling in clay, wax, or stucco.

All these are branches of sculpture (of which we shall occasionally make mention); but as they are ranged in their respective practice, under different denominations, we propose to give a history of the first branch (and chiefly of carving in stone and marble, which is at present peculiarly considered as the sculptor's art), and of its necessary preliminary, modeling in clay or wax.

Powers of sculpture. Sculpture is not only able, in common with other imitative arts, to express the forms of visible objects and the conceptions of the mind, but it possesses this superior distinction, that by means of its various branches, it is eminently capable of transmitting the most durable records of men's actions to distant ages. Were it not for this art, we should at the present moment be ignorant of every event which has distinguished the course of time in the long history of human existence; at least, our only knowledge would be gathered from tradition, whose fallacy and inaccuracy are every hour evinced. Without this art, we could form no conjecture of the permanency or variation of human forms, much less of human passions and taste; nor is it to be forgotten, that the first communication of the laws of God was made to the Israelites by the means of sculpture.

The art of sculpture, like its sister, painting, is initiatory, not for the gratification of the eye only, but also of the intellect. It is capable of expressing all forms that fall under our inspection, and of conveying more direct expressions of beauty than are to be found, either by ordinary observation, or are generally united in one body, and which are therefore called ideal forms.

Sculpture, in its confined and proper sense (in which we here propose to treat of it), divides itself into modeling of heads, and of statues, or groups: and these productions may be classed generally, like those of painting, under the respective terms, historical, allegorical, portraiture, &c. See Painting.

Bas-relief has been already described (see RELIEVO). Works of sculpture have been invented for the purpose of representing subjects of history or fancy, and may be regarded as a species of painting in stone. They are chiefly used to adorn the pediments, friezes, and panels of buildings, as well as the pedestals of statues, &c.

Statues are defined to be figures in full or imitated relief. They are of various descriptions or statues. They have chiefly been employed for the purposes of religious worship, as among the heathen nations and the Roman-catholics; and for the commemoration of heroic characters, or of men distinguished by any remarkable achievements.

Groups are an assemblage and union of statues, and are generally employed to the same purposes as single statues.

Of the methods of study. The studies necessary for the young sculptor, towards the attainment of his art, are so similar to those of the artist, that (with the obvious exceptions arising from the difference of materials employed in the two arts), that very little remains here to be enlarged on, under the head of studies. The principal acquisitions to which the student must direct his endeavours, are, a knowledge of composition, form (including anatomy), and expression; to which, as in painting, must be added the difficult study of grace. These are generally inured to, under the articles painting, design, drawing, and expression. See Drawing, Expression, and Painting.

The method of study most recommended to young sculptors, is, to begin with copying, and end with rivaling, the forms of the Greek statues.

"Vos exemplaria Graecae Nocturna versate manus, versate diurna!" says Da Frennoy: nor can it be questioned that the sculptors are generally speaking, direct guides to nature. But it should not pass unnoticed, that although the forms of the Greek sculpture are, in general, not only more beautiful, but more appropriately so than any other; yet in some instances they have been executed by modern sculptors, as in the forms of infants by Pimpane. See Statues, antique.

The method of execution in the Greek statues and other works of sculpture, seems to have been extremely different from that which is generally in use among modern artists. In the ancient statues, the artist frequently found striking proofs of the freedom and boldness that accompanied each stroke of the chisel, and which resulted from the artist's being perfectly sure of the accuracy of the method which he pursued. Even in the most minute parts of the figure, no indication of timorousness or diffidence appears; nothing that can induce us to believe, that the artist feared he might have occasion to correct his strokes. It is difficult to find, even in the second-rate productions of the Greek artists, any mark of a false stroke or a random touch. This firmness and precision of the chisel stroke is evidently to be ascribed from a more determined and perfect set of rules, than those of which we are masters.

Besides studying, therefore, in the productions of the Grecian masters, their choice and expression of select nature, whether beautiful, sublime, or graceful, together with that serenity and simplicity which pervade all their works, the artist will do well to investigate the manual and mechanical part of their operations, as this may lead to the improvement of his mode of progress.

It is certain that the ancients, almost always formed their first models in wax; to this modern artists have substituted clay, which they prefer on account of its yielding nature, and its sticking in some measure to every thing it touches. We must not, however, imagine from hence, that the method of forming models of wet clay, was either unknown or neglected among the Greeks; on the contrary, the art of this kind was so much admired, that in the Villa Albani. These clay models were then turned by their mails, to render certain parts more delicate and lively; hence arose the phrase, ad unguem factus homo, "an accomplished man." It was the opinion of count Caylus, that the ancients did not use models in forming their statues. But to dispute this, it is only necessary to mention an engraving on a stone, in the cabinet of Horsch, which represents Prometheus engraving the figure of a man, with a plummet in his hand, to measure the proportions of his model.

As soon as the artist has rendered himself familiarly acquainted with the beauties of the Grecian statues, and formed his taste on the admirable models they exhibit, he may then proceed with advantage and success to the imitation of nature. The ideas he has already formed of the perfection of nature, by observing her dispersed beauties, and combined and collect catholic in the compositions of the ancient artists, will enable him to acquire with facility, and to employ with advantage, the detached and partial ideas of beauty which will be exhibited to his view in a survey of nature in her actual state. When he discovers these partial beauties, he will be capable of combining them with those perfect forms of beauty, with which he is already acquainted. In a word, by having all the models of ancient artists already mentioned, he will form an accurate judgment of the powers of his art, and will draw rules from his own mind.

There are, however, two ways of imitating nature. In the one, a single object occupies the artist, who endeavours to represent it with precision and truth; in the other, certain lines and features are taken from a variety of objects, and combined and blended into one regular whole. All kinds of copies belonging to the first kind of imitation blend the productions of this sort must necessarily be executed in a confined and servile manner, with high finishing, and little or no invention. But the second kind, called imitation, is made directly to the investigation and discovery of true beauty, of that beauty whose perfect idea is only to be found within the mind.

Of the different modes of process in sculpture. Works of sculpture are performed, either by hollowing or engraving, as in metals, agates, and other precious stones, and in marbles of every description; or by working in relief, as in bas-reliefs in the materials just mentioned, or in metal, clay, wax, marble, or stone.

The excavation of precious stones forms a particular branch of art called intaglio, which, together with the working them in relief, when the term cameo is applied to them, belongs to the art of seal-engraving. See Engraving.

The excavation of metals constitutes the art of engraving, in its various branches, or the art which is comprehended in the term engraving, comprising projecting, casting in bronze, &c.

Of the last only, viz. casting in bronze, we take this opportunity of observing, in addition to the account given under the head
Sculpture.

SCULPTURE.

bromes, that a highly improved method has lately been put in practice by professor Zander, an eminent sculptor at Vienna, in the case of emperors Joseph II. The student may find an accurate detail of Zander's mode of process, in the "Academic Annals of Painting," published by the royal academy of London.

We proceed, as before proposed, to the other more immediate and proper parts of the sculptor's art.

The process of hollowing hard stone or marble, will need no particular description; especially as it is now wholly in disuse, except for the forming of letters in monumental or other inscriptions.

In working in relief, the process is necessarily different, according to the materials in which the work is performed.

As not only the beginning of sculpture was in clay, for the purpose of forming statues, but as models are still made in clay or wax, for every work undertaken by the sculptor, we shall first consider the method of modelling figures in clay or wax.

Few tools are necessary for modelling in clay. The clay being placed on a stand or easel, the artist begins to work with his hands, and puts the whole into form by the same means. The most expert practitioners of this art seldom use any other tool than their fingers, except in such small or sharp parts of their work, as the fingers cannot reach. For these occasions, they are provided with three or four small tools of wood, about seven or eight inches in length, which are rounded at one end, and at the other flat and shaped into a sort of claws. These tools are called by the French bouchons. In some of these the claws are smooth, for the purpose of smoothing the surface of the model; and in others are made with teeth, to rake or scratch the clay, which is the first process of the tool on the work, and in which state many parts of the model are frequently let by artists, to give an appearance of freedom and skill to their work.

If clay could be made to preserve its original moisture, it would undoubtedly be the finest substance for the models of the sculptor; but when it is placed either in the fire, or is exposed in a dry air, its parts are more or less hard and brittle in the air, its solid parts grow more compact, and the work shrinks, or loses a part of its dimensions. This diminution in size will be of no consequence, if it affected the whole equally, so as to preserve its proportions. But this is not always the case: for the smaller parts of the figure drying sooner than the larger; and thus losing more of their dimensions in the same space of time, than the latter do; the symmetry and proportions of the work inevitably suffer.

This inconvenience, however, is obviated by forming the model first in clay, and moulding it in plaster of Paris before it begins to dry, and the taking a plaster cast from that mould, and the repairing it carefully from the original work; by which means you have the exact counterpart of the model in its most perfect state; and you have, besides, your clay model to work from.

In order to model in wax, you must prepare the wax in the following manner: to a pound of wax add half a pound of scannomy (some mix turpentine also), and melt the whole together with oil of olives; putting more or less of it as you would have your modelling wax harder or softer, also some of your blue sable mixed with this composition, to give it a reddish colour, in imitation of flesh.

In modelling in wax, the artist sometimes uses his fingers, and sometimes tools of the same sort as those described for modelling in clay. It is at first most difficult to model in wax than in clay, but practice will render it familiar and easy.

Of the use of the model. Whatever considerable work is undertaken by the sculptor, whether has-relief, or statue, &c. it is always requisite to form a previous model, of the same size as the intended work; and the model being perfected, according to the method before described, whether in clay, or in wax, or a cast in plaster of Paris, becomes the rule, whereby the artist guides himself in the conduct of his work, and the standard from which he takes all its measurements. In order to render the place handled more correctly by it, he puts over the head of the model an immoveable circle, divided into degrees, with a moveable rule fastened in the centre of the circle, and likewise divide the division of the circle, and thereby the rule hangs a line with a lead, which directs him in taking all the points, which are to be transferred from the model to the marble; and from the top of the marble is hung the lead on that line is hung from the model; by the correspondence of which two lines, the points are ascertained in the marble.

Many eminent sculptors prefer measures taken by the compasses to the method just described; for this reason, that the model is moved but so little from its level, the points are no longer the same.

This method, however, offers the best means, by which models in judgement may be attained; but it is manifest, that enough yet remains to exercise and display the genius and skill of the artist. For, first, as it is impossible, by the means of a straight edge, tangent to this curve of a curve, to derive a certain rule to guide him, as often as the line which he is to describe deviates from the direction of the plumb-line. It is also evident, that in order to determine exactly the proportion, which the various parts of the figure ought to bear to each other, considered in their mutual relation and connections. This defect, indeed, may be partly supplied by intersecting the plumb-lines by horizontal ones; but even this resource has its inconveniences; since the squares formed by transversal lines that are at a distance from the figure (though they are exactly equal), yet represent the parts of the figure as greater or smaller, according as they are more or less removed from our point of view.

Of sculpture in wood. A sculptor in wood should first take care to choose wood of the best quality, and the most proper for the work which he intends to execute. If he undertakes a large work, requiring strength and solidly, he ought to choose the hardest wood, as oak, elm, beech, or chestnut; but for works of moderate size, pear or apple-tree serve very well. As even these latter woods are still of considerable hardness, if the work consists only of delicate ornaments, the artist will find it preferable to take some more tender wood, provided it is at the same time fine-grained, and hard. The French sculptor, for instance, the Bouchardier tree, which is excellent for this purpose, as the chisel cuts it more neatly and easily than any other wood.

The ancients made statues out of almost every different kind of wood. At Sicyon the statue of Apollo was of box; the statue of Diana at Ephesus, was of cedar. As these two sorts of wood are extremely hard and enduring; and as cedar, in particular, is of such a nature, that, according to Pliny, it ought never to come to an end; the ancients preserved them for the lasting of their divinities.

In the temple built on mount Cyllene in honour of Mercury, Paternice relates, that there was a statue of that god made of cedron wood, eight feet in height. This wood was also much esteemed.

The cypress likewise, being a wood not apt to spoil, nor to be damaged by worms, was also used for statues; as were the palm-tree, olive, and ebony, of which latter, according to Pliny, there was another statue of Diana at Ephesus.

Several other kinds of wood were equally employed for this purpose, even the vine, of which the same author says, there were statues of Jupiter, Juno, and Diana.

Fulclum speaks of a French artist at Florence, of the name of Jann, who executed several statues in wood, in a style of finishing equal to marble, and particularly one of St. Beatus, which Bassini considered as a marvelous production.

The beauty of sculpture in wood consists in the tender manner of cutting the wood, free from all appearance of hardness or dryness.

For any work of large dimensions, even though it consists of a single figure, it is better to join together several smaller pieces of wood than to make the whole of a single large piece; which is more able to warp and spring from the shrinking or swells of the grain, that always dry at heart, although it appears perfectly dry on the outside.

No wood can be properly fit for works of this kind, that was not been cut at least ten years before it is used.

The tools used for sculpture in wood, are the same as those of the joiner or cabinet-maker.

Of sculpture in stone and marble. For sculpture in marble and other stone, the artist must make use of tools of good steel, well tempered, and of strength proportioned to the hardness of the material.

The first thing to be done, is to saw out from a larger block of marble, a block proportioned to the size of the work which is undertaken. After this, the sculptor shapes the gross masses of the forms he designs to represent, by knocking off the superfluous matter with a strong mallet or bed, and a strong steel tool called a point. When the block is thus hewn out agreeably to the measure previously taken for the performance of the work, the sculptor brings it closer to the intended form by means of a finer point; and sometimes of a tool called a dog's tooth, having two points, but less sharp than the single one.
SCULPTURE.

After this he uses the gradine, which is a flat cutting tool, with three teeth, but is not so strong as the point.

Having advanced his work with the gradine, he uses the chisel to take off the ridges left by the former tool. He is delicate in the use of this instrument, and, giving softness and tenderness to the figure, till at length, by taking a rasp, which is a sort of file, he brings his work into a proper state for being polished.

Raspes are of several kinds, some straight, some curved, and some harder or softer than others.

When the sculptor has thus far finished his work with the chisel and rasp, he procures, whatever certain parts or particular works require polishing, he uses pumice-stone to make all the parts smooth and even. He then goes over them with tripoli, and when he would give a still higher gloss, he rubs them with leather and straw-ashes.

Besides the tools already mentioned, sculptors use also the pick, which is a small hammer pointed at one end, and at the other formed with teeth made of good steel and squared, to render them the stronger. This serves to break up a block of marble, and dig them with a hole of equal dimensions, which cannot be done with cutting tools. The chisel is driven with the maltel or beetle, and its points bruise the marble and reduce it to powder. Water is thrown into the hole from time to time, and this water that is made, to bring out the dust of the marble, and to prevent the tool from heating, which would destroy its temper; for the free-stone dust on which tools are edged, is only moistened with water to prevent the iron from heating and taking off the temper of the tool by being rubbed dry; and the trepanns are wetted for the same reason.

The sculptor uses the bouchard to bore or pierce such parts of his work as the chisel cannot reach, in danger of spoiling or breaking them. In using it, he passes it through a piece of leather, which leather covers the hole made by the bouchard, and prevents the water from spurring up in his face.

The other tools necessary for sculpture on marble or stone, are the rounded, which is a sort of rounded chisel; the bouget, which is a chisel-squared and pointed; and various compasses to take the requisite measures.

The process of sculpture in stone is the same as in marble, excepting that the material being less hard than marble, the tools used are not so strong, and some of them are of a different form, as the rasp, the hand-saw, the tipe, the straight chisel with three teeth, the rounded, and the grater.

If the work is executed in free-stone, tools are employed which are made on purpose, as the free-stone is apt to scale, and does not work so nicely like marble. Sculptors in stone have commonly a bowl in which they keep a powder composed of plaster of Paris, mixed with the same stone in which their work is executed. With this composition they fill up the small holes, and repair the defects which they meet with in the stone itself.

HISTORY OF SCULPTURE.

Adantic art.

The art of sculpture is of such immemorial antiquity, that it has been by some conceived to have had its being from eternity; but without regarding it in this exalted light, St. Augustin has attributed a date to its invention as early as the time of the Protopen, our common father Adam, who, as authors, was the inventor of letters. Sculpture, therefore, may trace its pedigree from the infancy of the world, and contend for pre-eminence with the most remote antiquities which it has been employed to celebrate. Josephus, Cteschem, and some other authors, make mention of some antediluvian sculptures in stone and brick erected at Joppa, which are imagined to have contained the systems of idolatry and celestial sciences, and to have remained unburnt for some thousands of years after the universal cataclysm.

Cham, who is supposed to be the same as Zoroaster, is spoken of by the author of the scholastic work on Geography, as having engraved the liberal arts on fourteen columns, seven of brass, and seven of brick. Socrates also mentions the same circumstance, with this variation, that they were engraved on plates of different metals (diversa metalorum laminis).

Concerning the art of sculpture immediately after the Flood, it is scarcely to be questioned that it was transmitted by Noah and his descendants. About two hundred years after the Deluge, Mercenarius Trismegistus reports of himself, that he engraved his most abstruse mysteries on stone, reforming all that had been deprived by Cham. Some of these records were in letters, some in figures and engravings characters, probably not unlike to those contained in the stupendous obelisks erected by Misra, the first Egyptian Pharaoh, about four hundred years (according to Kirschen) before Moses.

The first mention that is made of the art of sculpture in the writings of Moses, is in the book of Genesis, where we are informed that when Jacob, in obedience to the divine command, was returning from Padan, he carried his wife Rachel along with her the pharama, or idols, of her father's house. These must certainly have been very small images, since Rachel found it so easy to conceal them from her father, notwithstanding his anxious search; but we are ignorant in what form they were made, or of what materials they were composed. The first persons mentioned in the Bible as artists, are Aboliah and Benjama, who, according to some, covered the mercy-seats, and wrought the ornaments of the pectoral to be worn by the high priest.

As Chaldea, therefore, was the first people of the earth after the Flood, and as it appears from various accounts that the art of engraving upon bricks baked in the sun was there carried to a considerable degree of perfection at a very early period, it appears probable that the Chaldeans derived the rudiments of the art of sculpture immediately from their antediluvian ancestors.

The origin of idolatrous worship is generally thought to be derived from images first made to preserve the memory of the dead, and, in process of time, converted by the flatterers of great men into objects of adoration. This also affords presumptive evidence that the Chaldeans were the first who practised the art of sculpturing, and stone into the figures of men and other animals; for the Chaldeans were unquestionably the first idolaters, and their early progress in sculpture is confirmed by the several testimonies of Berosus, Alexander, Polybius, and Pliny.

Against this conclusion some plausible arguments have been urged on the authority of a theory established by a French writer, who maintains that in the year of the world 1490, about 200 years after the Deluge, the Scythians under Brooma, a descendant of Magog, extended their conquests over the greater part of Asia; and that Brooma was not only the civilizer of India, and the author of the Brahminical doctrines, but also diffused the principles of the Scythian mythology over Egypt, Phenicia, Greece, and the continent of Asia.

Leaving the consideration of this question, as too extensive for our present purpose, we proceed to trace the progress of the art of sculpture through some other nations of antiquity, till we bring it to Greece, where it was carried to the highest perfection to which it has yet attained.

Phoenicia, in the immediate vicinity of Chaldea, must necessarily have very early acquired a knowledge of sculpture. The Phoenicians possessed both a character and situation highly favourable to the cultivation of this art. They beheld the most beautiful models in their own persons, and their industrious character qualified them to attain perfection in every art for which they had a taste. But as their situation raised a spirit of commerce, it is at all times questionable whether commerce induced them to cultivate the arts. Their temples shone with statues and columns of gold, and a profusion of emeralds were everywhere scattered; but the beauties of art do not consist in finery or ostentation of wealth. The temples of the Phoenicians have been unfortunately destroyed; many Carthaginian models indeed are still preserved, ten of which were deposited in the cabinet of the grand duke of Florence. But though their architects were a colony of Phenicians, we should probably deduce from their works a very unfair estimate of the merit of their ancestors.

Very high pretensions to antiquity of every kind are made by the Persians; but we do not and that they ever made any distinguished figure in either of the arts of sculpture or painting. They were indeed sensible to the charms of beauty, but they did not study to imitate them. Their dress, which consisted of long flowing robes, concealing the whole person, prevented them from attending to the beauties of form. Their religion too, which taught them to worship the divinity in the emblem of fire, and that it was impious to represent him under a human form, seemed almost to prohibit the exercise of this art, by taking away the strongest incentives to art during the reigne of superstition; and as it was not customary among them to raise statues to great men, it was impossible that statuary could flourish in Persia.
The Persian, however, represented in their bas-reliefs many symbolic expressions of the powers of the Divinity, as well as of their religious ceremonies or heroic achievements. The bas-reliefs on the palace of Persopolis and the bulls of the Brahmans, are arranged in horizontal and perpendicular lines, answering the double purpose of description and architectural decoration. The style of drawing in these bas-reliefs resembles that of later hieroglyphics, except in the dresses of the figures, which are different from those either of the Egyptians or Hindoos. The Persians are represented with long beards and ringlets, caps, full tunics, with regular folds and large sleeves. The Medes, in the same ruins of Persopolis, have close tunics. The drapery in these bas-reliefs is superior to that of the Egyptians, as bearing a greater resemblance to nature.

In Hindostan and Egypt the art of sculpture has been exercised in a similar manner in the shaping or adorning large rude masses of the hardest materials, and the works of these two nations may not improperly be considered together. The reader will find some account of their sculpture under the article ANTIQUITIES.

In India, bas-reliefs have been found in great numbers in the caves of Ellora and Elephants: the subjects are religious. The drawing of the figures bears a strong resemblance to the Egyptian style, but they are less correct in their forms, the heads being generally very large, and the limbs disproportionate to the bodies. It may be questioned, from the greater simplicity of execution, whether the Egyptian hieroglyphics are not also more ancient than the Hindoos; the ground in the former being level with the highest relievo, and in the latter cut down to the lowest outline of the figure.

The character and style of design among the Egyptians have been more fully noticed by writers, because the first progress of the art among that people is conceived to elucidate that of most other antient nations.

In the Egyptian idols, composed of parts of different animals, each part appears to have been separately studied; for it is not to be supposed that a people of such rude manners as the Egyptians would communicate to their works that refinement and beauty which the elegance of Greekian manners inspired. On the other hand, there are many of the Tuscan statues which bear so close a resemblance to those of Greece, that antiquarians have thought it probable that they were conveyed from that country or Magna Grecia into Etruria, about the time of the Roman conquest, when Italy was adorned with the spoils of Greece.

Among the monuments of Etrurian art, two different styles have also been observed. In the first the lines were straight, the attitude stiff, and the shape of the head without beauty. The general form of the figure is likewise too slender: the head is oval, the chin peaked, the eyes flat, and looking obtuse.

All these are evidently the defects of an art in a state of infancy, and some of them are equally conspicuous in the early statues of all nations. The style of the Etrurian sculpture is so similar to that of the Egyptians, that one is almost induced to suppose...
that there had once been a communication between these two nations; but the introduction of this style by Dedaus is generally credited.

Winckelmann supposes that the second epoch of sculpture in Etruria commenced in Etruria about the time at which it had its greatest perfection in Greece, in the age of Phidas; but this conjecture is not supported by any proofs. To describe the second style of sculpture among the Etruscans, is almost the same as to describe the style of the modern restorers of the art in Tuscany. The joints are strongly marked, the muscles raised, the bones distinguishable, but the whole appearance is harsh, particularly in the representation of ordinary life. The statues of the gods are designed with more delicacy. In forming them the artists were anxious to show that they could exercise their power without that violent distention of the muscles which they conceived necessary in the exertions of beings merely human; but in general their attitudes are unnatural, and the actions strained. If a statue, for instance, holds any thing with its fore fingers, the rest are stretched out in a stiff position.

Greek. The earliest examples of Grecian sculpture remind us still more of the Egyptian, in the principles of design, than those of any other nation. The face of the human figure has the same kind of oval, the eyes are described by the same curves, the eye full, and the body and limbs represented nearly in the same general forms. The works of the early Greeks may, however, be justly considered as being marked out in the proportions of their figures, and superior in the drawing of the body and limbs. It is probable that sculpture preceded the use of letters in Greece, as in other nations; but the small bronze figures with inscriptions on them in Cadiunan letters, are such weak and barbarous resemblances of the human form, that it is needless to trace its origin in any more remote period.

The Greeks began very early to study the proportions of the human form. Vitrivius informs us that "as the height of the human figure was six times the length of the foot, that was made the rule of proportion for the Doric column." Their knowledge, therefore, in this point of art, was by no means insufficient to their architectural proportions.

Whether Greece received the principles of the arts from Egypt and Phœnicia, or, as they asserted, were the original inventors of them, it is certain that the native genius of the Grecians, combined with other particularly favourable circumstances, very soon raised sculpture from a state of barbarism. In the earliest era of sculpture in Greece, schools of design were established in the island of Zeeina, at Corinth, and at Sicyn. This last city was styled the mother of the arts, as Diapason and Selphides, and their disciples also, had flourished there; and after seven generations, Aristotle, the brother of Canaceus, likewise a sculptor of eminence, presided over the same establishment with undiminished fame. The school of Zeeina travelled its origin to Dedaus, of fabulous renown; and Sicyn, said to have produced two statues of Juno; one for her temple at Samos, and the other for that at Argos.

From these auspicious drawings of the art of sculpture, three distinct schools arose; one of which was peculiar to Ionia; the other were in Greece, at Athens, and at Sicyn, each of them shining with nearly equal splendour for several ages. At the head of the first Grecian artists, stands Myron, whose statues in bronze at Athens were admired in the sixteenth Olympiad. A Discothek, made by Myron, is particularly noticed by Quinctilian.

Phidas, whose name is better known in the present day than that of any other sculptor, was the disciple of Echias and Agesilaus, the probable contemporaries of Myron, and who flourished in the sixteenth Olympiad. We collect from Quinctilian, that he excelled in imparting a celestial dignity to his figures of the deities, two of which are celebrated in this respect, the Minerva at Athens, and Jupiter Olympius at Elis. Many of his most beautiful works were in ivory, frequently less than the natural size. He cast likewise in bronze.

In the same age lived Polycletus, whose works were distinguished by exquisite grace and most correct finishing; the latter quality was the effect of his singular diligence. To judge of the human figure he is said to have given more than human form, but founded in expressing the majestic character of the gods.

The works of Egesias were of a sublime style, but hard manner.

Of the school of Phidas, the most distinguished sculptors were Alcmenes of Athens, and Agorasitus of the island of Paros. Their rival skill was exerted in finishing a statue of Venus; and the palm was adjudged by the Athenians to their own citizen.

Polycleitus of Sicyn, the competitor with Phidas in an understanding of more grandeur and consequence than his general works. He was employed by the inhabitants of Argos to make a colossal statue of Juno, composed of gold and ivory, in order to emulate, rather than to imitate, the Olympic Jupiter of Phidas.

Two figures in bronze by Polycleitus representing the canopher or nymph bearing in baskets the symbols of Ceres to a sacrifice, were taken from the Thebians by Verres. They were esteemed beyond any bronze figures existing at that time. Such was the skill of this eminent master, that he completed so perfect a human figure that it served as a model to his successors, and was admired by Lyssippus as the acme of his art.

While Phidas in gold and ivory, and Polycleitus in bronze, engrossed to themselves every excellence, Scopas acquired a scarcely inferior celebrity for his statues in marble. The group of Niobe and her children is attributed by Piny to Scopas or Praxiteles, he does not decide which.

The last sculptor (of whose works we have any knowledge) ceasal with Phidas, was Ctesilaus, who, jointly with him and Polycleitus, designed, one of the three Amazons designed to decorate the temple of Diana at Ephesus, and the statue of Pericles, commended by Piny, who allows to Ctesilaus the felicity of giving to his heroes a still more airy air than they possessed.

The names of Policles, Cephisodorus, Leochares, and Hippodotus, are preserved from oblivion by Piny, but none of their works remain. Leochares was one of the four artists employed in adorning the miliarium built by the celebrated Artemisia, queen of Caria, to the memory of her husband.

Menestratus, Socrates, Philiscus, Lyais, Memenides, and many others, are also spoken of with praise by various writers; but we have unfortunately no other remaining testimonies of their merits.

Of the first style of the Grecian sculptors, so remarkable for simplicity and gracefulness, the era was circumscribed to the limits of fifty years, during which period the art had arrived at its meridian of beauty. The succeeding age introduces Praxiteles, who may be called the father of the second manner, and whose works were discriminated by their flowing outline and delicate finishing. The elevation of Thelus by Eupemnonius above the other states of Greece, produced a complete change in her whole system; but as soon as the Athenians recovered their former splendour, the arts, which had ever accompanied the vicissitudes of her fortunes, revived with an unabated splendour. The works of Praxiteles are celebrated by historians and poets. His Venus of Guidius in marble, attracted them no less admiration than the Medicean Venus has done in the modern world; and his giant statue of a bull, immortalized in the trunk of the tree against which he leans) Samocetus, is still among the most prodigious productions of sculpture.

Not long after Praxiteles had signified himself in Italy, and particularly in Rome, Lyssippus appeared, whose great merit consisted in following nature more scrupulously than any of his immediate predecessors. If, as Pliny reports, his works were so numerous as to amount to not less than fifteen; the works of Praxiteles, we have the more cause to regret that they were all of bronze, and are irretrievably destroyed. He flourished under the reign of Alexander.

To Aganderus, Polydoronus, and Athenodorus, is ascribed (by Pliny) the celebrated group of the Laocoon and his sons, and the art has been frequently busied in endeavouring to discriminate the particular portion of each artist; but conviction has hitherto been produced. Abbé Winckelmann conjectures that Aganderus was the father of the other two artists, and that he himself finished the statue of Laocoon, leaving the children to be wrought by his son Polycrates (or Juliaus apellis). No authentic document remains by which the time in which these artists flourished can be ascertained.

Neither do we know the precise date of Apollonius and Taurinus, the authors of a less celebrated group representing Daedalus tied to the horns of a bull (in order to be precipitated into the sea) by Zeilus and Amphion, the sons of Antiope. This work is generally supposed to have been executed by the rival group of Laocoon. In an inscription on it, now obliterated, was traced the name of another artist, Menecrates. This vast mass of sculpture is said to have been formed out of a single block, in the island of Rhodes. It has suffered greatly in the course of time.

Greece, after the death of Alexander the Great, lapsing into a state of dependence little short of slavery, the arts were for a time wholly neglected; and when they were revived (after the amnesties, had they not found refuge in Asia, under the patronage of the Seleucides, Men of talents also in every profession.
SCULPTURE.

Winckelmann has assigned four different styles to this art among the Greeks. The antient style, which continued until the time of Phidias; the grand style, formed by that celebrated statues; the beautiful, introduced by Praxiteles, Apelles, and Lyssippus; and the imitative style practised by those artists who copied the works of the antient masters. The most authentic monuments of the antient style have been already described. The statues formed in this style were not distinguished by beauty of shape, nor by proportion, but bore a close resemblance to those of the Egyptians and Etruscans. The eyes were long and flat; the section of the mouth not horizontal; the chin was pointed; the curls of the hair were ranged in little rings, and it was impossible to inspect the head to distinguish the sex.

The character of the antient style was energetic, but harsh; it was animated, but without gracefulness; and the violence of the expression deprived the whole figure of beauty. The great group of Hercules, which was erected by Phidias, Polycletus, Scopas, Alcamenes, Myron, and other illustrious artists. It is probable, from some passages of antient writers, that in this style were preserved some characteristics of antient manners, such as straight lines, the squares, and angles. The antient masters, such as Polycletus, being the legislators of proportion, says Winckelmann, and of consequence thinking they had a right to distribute the parts of the human body, have undoubtedly sacrificed some degree of the form of beauty to grandeur which is harsh, in comparison of the flowing lines and graceful forms of their successors. The most considerable monuments of the grand style, are the statues of Niobe and her daughters; and a figure of Pallas, to be seen in Villa Albani; which, however, must, not be confounded with that preserved according to the first style, and also found in the same place; the head of which possesses all the characters of dignified beauty, at the same time exhibiting the rigidity of the antient style. Elegy and ebullition have not, in the opinion of Winckelmann, that austerity of appearance which marks the age of the last-mentioned statue of Pallas. They are particularly characterised by grandeur and simplicity.

The third style was the graceful or beautiful. Lyssippus was, perhaps, the artist who introduced this style. Being more conversant than his predecessors with the flowing and beautiful lines of nature, he avoided the square forms which the masters of the second style had too frequently admitted. He was of opinion that the art ought rather to please than to astonish, and that the aim of the artist should be to raise admiration by giving delight. The artists who cultivated this style did not, however, neglect to study the sublime works of their predecessors. They knew that grace is consistent with the most dignified beauty; and they made use of the same features which those forms are enhanced by dignity. Grace is inspired into all the movements and attitudes of their statues. It appears in the delicate turn of the hair, and even in the adjusting of the drapery.

The last, or imitative style, is of an inferior degree of excellence to that which has just been mentioned. The great reputation of Praxiteles and Apelles raised an ardent emulation in their successors, who, desiring to surpass such illustrious masters, were satisfied with imitating their works. Every species of beauty of form appears to have been well known to the antients; and great as the ravages of time have been amongst the works of art, specimens are still preserved in which can be distinguished dignified beauty, attractive beauty, and a beauty peculiar to tender age. A specimen of dignified beauty, which Thoma says, was the most excellent model of infant beauty which antiquity has transmitted to us, is a satyr of a year old, which is preserved, though a little mutilated, in the Villa Albani.

Nor were the sculptors who represented these admirable productions of the human form, regardless of the drapery of their statues. They clothed their figures in the most proper stuff, which they wrought into that shape which was best calculated to give effect to their design.

The vestiment of the linen in Greece generally consisted of linen cloth, or some other light stuff, and in latter times of silk, and sometimes of woollen cloth. They had also garments embroidered with gold. In the works of sculpture, as well as in those of painting, one may discern the taste of the time by the transparency and small folds. The other light stuffs which were worn by the women, were generally of cotton, sometimes striped, and sometimes ornamented with a profusion of flowers. Silk was also employed; but whether it was known in Greece before the time of the Roman emperors, cannot easily be determined.

The vestiments of the Greeks, which deserve particular attention, are the tunic, the robe, and the mantle.

The tunic was that part of the dress which was next to the body. It may be seen in the Flora Parnese, and in the statues of the Amazons in the Capitol. The youngest of the daughters of Niobe, who throws herself into her mother's arms, is clothed only with a tunic. It was of linen, or some other light stuff, without sleeves, fixed to the shoulders by a button, so as to cover the whole breast. Some of the tunics of the goddess Ceres, and of comedians, have long straight sleeves.

The robes of women commonly consisted of two long pieces of woollen cloth, without any particular form, attached to the shoulders by a great many buttons, and sometimes by a clasp. They had straight sleeves, which came down to the wrists. The young girls, as well as the women, fastened their robe to their side by a cincture, fastened on the side in a knot; as it is still done in many parts of Italy. Sometimes these tunics were embroidered with a rose in shape, which has been particularly remarked in the two beautiful daughters of Niobe. In the younger of these, the cincture is seen passing over the shoulders.
and the back. Venus has two cineraria, the one passing over the shoulder, and the other surrounding the arm. The latter is the cestus so celebrated by the poets.

The mantle was called peplos by the Greeks, which signifies properly the mantle of Pallas. The name was afterwards applied to the mantles of the other gods, as well as to those of men. This part of the dress was not square, as some have imagined, but of a roundish form. The antients, indeed, speak in general of square mantles, but they received this shape from four tassels which were affixed to them: two of these were visible, and two were concealed under the mantle.

The mantle was brought under the right arm, and over the left shoulder; sometimes it was attached to the shoulder by two buttons, as may be seen in the beautiful statue of Lucullus at Villa Albani.

With respect to the head, women generally wore no covering but their hair; when they wished to cover their head, they used the corner of their mantle. Sometimes we meet with veils of a fine transparent texture. Old women wore a kind of bonnet upon their head, an example of which may be seen in a statue in the capitol, called the Prasina; but Wickenmann is of opinion that it is a statue of the Vestal Virgins. The covering of the feet consisted of shoes or sandals. The sandals were generally an inch thick, and composed of more than one sole of cork. Those of Pallas in Villa Albani have two soles, and other statues had no less than five.

But in no part of art are the Grecian sculptors more eminently excellent than in the general characteristic expression which they gave to their figures.

The most elevated species of tranquility and repose was studied in their figures of the gods. The father of the gods, and even inferior divinities, are represented without emotion or representation. But Jupiter is not always exhibited in this tranquil state. In a bas-relief belonging to the marquis Ron- di, he appears seated with a melancholy aspect. The Apollo, once called of the Belvedere, and representing the act of discharging from his bow the mortal shaft against the serpent Python, to express the action of a hero, the Grecian sculptors dedicated the countenance of a noble and attentive character representing his ganoes, and allowing no expression of pain to appear.

Philoctetes is introduced by the poets shedding tears, uttering complaints, and rending the air with his groans and cries; but the artist exhibits him silent, and bearing his pains with dignity; in the same manner as the Ajax of the celebrated painter Timonoma- chus was not drawn in the act of destroying the sheep which he took for the Grecian chief, but in the moments of reflection which succeeded that frenzy.

Illustrious men, and those invested with offices of dignity, are represented with a noble assurance and firm aspect. The statues of the Roman emperors (executed by Greek artists) resemble those of heroes, and are far removed from every species of inatten, in gesture, in the attitude, and action. They never appear with haughty looks, or with the splendor of royalty. None but captives are ever represented as offering any thing to them with bended knee.

The Greek works of ivory and silver were not always of a small size. The colossal bust of a man composed of these materials was twenty-six cubits high. It is indeed scarcely possible to believe that statues of such a size could entirely consist of gold and ivory. The quantity of ivory necessary to form a statue a foot broad in modern conceptions. M. de Pauc calculates, that the statue of Jupiter Olympus, which was 54 feet high, would consume the teeth of 300 elephants.

The Greeks generally heaved their marble statues so that when they afterwards worked the heads separately, and sometimes the arms. The heads of the famous group of Niope and her daughters appear to have been adapted to their bodies after being separately finished. It is proved by a large figure representing a river, which is preserved in Villa Albani, that the antients first heaved their statues roughly, before they attempted to finish any part. When the statue was received its perfect figure, they next proceeded to polish it with pumice-stone, and again carefully retouched every part with the chisel.

The amateurs, when they employed porphyry, usually made the head and extremities of marble, and then covered it with porphyry. There are four figures entirely composed of porphyry; but these are the productions of the Greeks of the middle age. They also made statues of basalt and alabaster.

The amateurs, as well as the moderns, made works in plaster; but no specimens remain except some figures in bas-relief, of which the most beautiful were found at Baiae, near Naples.

We have been thus minute in our account of the Grecian sculpture, because it is the opinion of the ablest critics, that modern artists have been more or less eminents, as they have studied with the greater or less attention the models left us by that ingenious people. Wickenmann goes so far as to contend, that the most finished works of the Grecian masters ought to be studied in preference even to the works of nature. The reason assigned by the abbe for his opinion is, that the fairest image of beauty are more easily discovered, and make a more striking and powerful impression, by their reunion in these sublime copies, than when they are scattered far and wide in the original of nature. Allowing, therefore, the study of nature the high degree of merit its so justly claims, it must nevertheless be granted, that it leads to true beauty by a much more tedious, laborious, and difficult path, than the study of the antique figures immediately to the artist's view the object of his researches, and combines in a clear and strong light the various rays of beauty that are dispersed through the wide domain of nature. By this means, the artist may be admitted, without great allowances for the peculiar creed of the writer.

Decline of Grecian sculpture.

When the restful genius of the Grecians, and the aggressive spirit of the Romans, are compared to the second thralom of the Greek states, and L. Mummius was directed to lay siege to Corinth, the capture of a city so famed as the repository of all that was most perfect in the arts, provoked the avarice of the conqueror; who, by transporting many of the most superb works of art to Rome, to grace his triumph, excited in his followers an ardour of possessing treasures of the same kind, as totally transferred the seat of the arts from Athens to the growing metropolises of the world.

Sicily, at the same period, had been ravaged by M. Sertorius, and Sparta by Mucrion and Varro; and Greece began to be exhausted of all it once boasted in art. Nor was the fate of the arts in Egypt more auspicious, whence, after the defection of Seleucus, they took refuge in the court of Attalus; but their security was short of short duration. On the death of Attalus, his territory devolved to the Romans; and the treasures of sculpture which adorned his palace, were also transferred to Rome.

Rome. After taking a view of the extinction of the arts in Greece, we may find some satisfaction in directing our minds to the introduction of them at Rome, and to the liberal encouragement which they have experienced even from their haughty and rapacious conquerors.

Petiles, a name which has been confounded with Praxiteles, was a native of Calabria; who, in a statue in the Capitol or of Roscius, the celebrated actor, as an infant lying in a cradle, and curiously, by a serpent, a situation of danger from which his nurse is said to have preserved him. Nearly about the same time, Archelaus and Evander were in great re-
SCULPTURE.

most exclusively, by Greek sculptors. Julius
Cæsar, who, in a private station, had
made an extensive collection of marbles, and
small figures in ivory and bronze; and who,
when dictator, dedicated them as a public
benefaction in the temple of Venus Genetrix;
may be said to have left the love of the arts
in the possession of the Roman.
Augustus, after he assumed the imperial
government, dispatched Memmius Regulus
to collect from every city of Greece the sta-
tues yet remaining in them. His orders were
so well observed, that the finest pieces of
sculpture were brought to Rome, with
precision by which his palaces were crow-
ed; and many were distributed in his
numerous villas. The Olympian Jupiter,
Phidias, composed of gold and ivory, was
placed on the only statue that escaped; the artists
of Greece asserting, that from the state of its
materials, it would not bear removal.
Augustus encouraged also the prevailing
mode of representing in statuary the most
distinguished characters of the age, and
placed many of their statues in public situa-
tions of eminence.
Succeeding emperors followed the ex-
ample of Augustus. We are informed by
Pausanius, that from the temple of Delphos
only, five statues were transported to Rome by
Nero, who also employed Zeuxoborus to cast
colossal statues of him in bronze 110 feet
high.
Nero, however, indulged the perverseness
of his taste in gilding, and otherwise disfigur-
ing, many of these exquisite works.
The triumphal arch built by Titus, and the
frieze in the temple of Minerva, built by Do-
mitian, give a very favourable idea of the
arts under those emperors.
In the sculpture of triumphal bas-reliefs
and trophies, the artist was particularly
eminent. The architectural plans adopted
by Trajan were of such magnitude, that men
of every kind of talents were invited to signal-
lize themselves under his munificent patro-
nage. His bridge over the Danube, his tri-
umphal arches, his monument of the column
which now bears his name, appear to have
given employment to all the powers
of human skill.
Under the auspices of Hadrian, the suc-
cessor of Trajan, the arts maintained a pro-
gressive degree of excellence. He was em-
ninently accomplished, not only as an admiral,
but was himself an artist. Every province
in Greece enjoyed his munificence; and the
temple of Jupiter at Athens, which he re-
stored, and that of Cyzicus, on the shores of
Propontis, which he built, were stupen-
dous monuments of imperial splendour. Hav-
ing for eighteen years been engaged in vi-
siting the most distant parts of the Roman
empire, he resolved to construct his villa at
Tivoli; in which, not only exact models of
the most celebrated buildings he had seen,
should be erected, but that they should be
furnished with originals, or the most copies,
of the most admirable statues. His correct
judgment in all works of art contributed more
to the absolute superiority of this collection,
thann the mere power of expending unlimited
treasures. Among these statues, erected by
Hadrian that the fashion of hav-
ing portraits in statuary was so generally ex-
tended amongst the noble and opulent citizens
of Rome. In his own villa at Tivoli were
placed, by him, these statues, not only of all his living, but of his de-
ceded, friends. Of his favourite Antonius,
in various characters, there are infinite re-
petitions. That most valued was found on
the Equiline hill, and was placed by Leo X. in
the Vatican, but it has lately been desolated
as Mercury, by the abate Visconti. Another
was found about 1770, in the Thermae Mar-
tani of Hadrian, near Ostia. It represents
Antinous in the mythological character of
Alcmane, in the labours of the collection of
the Lion J. Smith Barry, at Beaumont, in
Cheshire.
Some curiosity is excited to enquire
the names of those artists who were so con-
stantly employed, and so amply patronised,
by Hadrian. Those only of Aristeus, Papias,
and Zeno, occur on the plifths of fragments
discovered amongst the Tiburtine ruins.
We are now advancing rapidly to the de-
cline of sculpture among the Romans. Of
the two Antonines, M. Aurelius appears to
have been the greater friend of the arts. His
equestrian statue in bronze in the area of
the capitol, still defies the competition of the
modes last epoch. It includes the reigns of
Trajan, Hadrian, and the Antonines, and
terminates within that of Commodus. It was most remarkable for the
character and high-finishing of heads intended
as portraits, particularly of the imperial
busts, as of M. Aurelius, Commodus when
young, and of Lucius Verus.
A statue, said to be of that degenerate
monster Commodus, in the character of a
young Hercules, is in the Velverre; but the
superior style of the hair is a decisive proof,
according to the judicious Winckelmann, that
it is a genuine Hercules of much higher an-
tiquity.
But a far inferior state of sculpture, in
which none of its pristine elegance could be
raised, is apparent in the bas-reliefs of two
triumphal arches, erected at Rome in the
reign of Septimius Severus. The arts, how-
ever, cannot be supposed to have declined
in the sixth century, as the possession of the
artists who professed them; for many portraits
in marble, both of this emperor and his favour-
ite minister Plautinus, afford a convincing
proof, that the sculptors were many, yet
that the art was in a state of decadence.
The several authors who have pursued
this inquiry with the most ample and critical
investigation, are undecided in fixing the ex-
act period of the extinction of the arts at
Rome. Some allow no proofs of their ex-
istence later than the Gordians; and by
others they are extended to the reign of Li-
cinio Gallienus, in the 205th year of Chris-
tianity. Why the profession of the arts should,
in a great measure, cease, several causes
have been given; but the principal and most
obvious one is, that when Constantine deter-
minted to establish at Byzantium another ca-
pital of the Roman world, he pillaged the old
metropolis of its most valuable statuary, to
embellish a rival city. Those cities of Greece
also which were contiguous, supplied, of
course, an easy prey. Implied credit per-
haps is not to be given to an author of such
questionable veracity as Crusius; but from
him we learn, that Constantine had collected
the Olympic Jupiter of Phidias, the Galian
Venus of Praxiteles, and a colossal Juno, in
bronze, from her temple at Samos; not in
detail more of his catalogue. Those ac-
cording to Nicetas, were broken in pieces, or
melted down, at the surrender of the Eastern
empire, and its metropolis, in 1204, to the
French and Venetians. The four bronze
horses of the Capitol now in the church of
St Mark at Venice, were preserved from destruc-
tion, and transported in triumph.
From the reign of the first Byzantine
emperors, to the immediate successors of Theo-
dorus, we may perceive a ray of their former
fame, in the works of some Greek artists.
The historical columns of Arcadius now in no
very unequal estimation of those of Trajan
and Antonine at Rome. But from many
epigrams of the Antiquaries, it is evident that
able artists were to be found; and it may be
said to suppose, that such praise was not,
in every instance, extravagant or unmerited.
At the same time that Rome was laid waste
by the Goths, the works in bronze by the artists of Constantine were held in consider-
able estimation.
In the conclusion of his History of the De-
cline and Fall of the Roman Empire, the erudite Gibbon has given a perspicuous ac-
count of the causes to which the ruins of Rome may be ascribed.
During the fifteenth century, Petrarch and
Poggio, the celebrated Florentine rhetori-
cian and lawyer, very eloquently describe
the dilapidation by which they were sur-
rounded in their view of the imperial city.
After many centuries of injury sustained from
the Goths, the zeal of the primitive Christians,
the civil wars of her own nobility, and the
waste of materials, or the gradual decay of
time.
Poggio asserts, that six perfect statues
only remained, of all the former splendour
of the mistress of the world. Four were ex-
tant in the baths of Constantine; the others
were that now on the Monte-cavoile, and
the equestrian statue of M. Aurelius. Of
these, five were of marble; the sixth and last
is of bronze.
Poggio was the first collector of antique
sculpture, and from him the great Cosimo de
Medici acquired a passion for art, and
learned to enrich his cabinet with their pro-
ductions. His successors, with hereditary
emulation, exerted every power of wealth
and influence, to render that cabinet the
proud of Europe.
An investigation of the remains of Roman
grandeur, so long and sedulously pursued,
was rewarded by frequent discoveries of the
finest antique sculptures; and the artists of
the modern schools established at the Flo-
rence, gave the first proofs of their ingenuity
in restoring and adapting those precious frag-
ments.
Many curious particulars relative to the
discovery of antique statues in the sixteenth
century, may be found in Ficoroni, in an ac-
count by Flaminius Vaccar, printed at the
end of Nardini's Roma Antica, and in Mont-
facon. Several of these are also to be found
in Deyray's Anecdotes, from which many
parts of this account of the arts have been
selected.

Modern art of sculpture.
Of the sculptors of the modern school, the
first who are deserving of notice are Niccolo
Pilati, and his son Giovanni, whose works
in bas-relief became the principal ornaments of the cathedrals which were built in Italy in their time. They were born at Pisa, and flourished in the middle of the 13th century. To their names is to be added that of Niccolò dell'Arca.

To these succeeded Donatello, born at Florence, in 1386, whom an Italian author calls the reveiler of sculpture: and Lorenzo Ghiberti, celebrated for his admirable bas-reliefs in bronze on the gates of the Baptistery of St. John at Florence, of which Michael Angelo said, that they deserved to be the gates of Paradise. The compartments of these gates are filled with subjects taken from the Old Testament. The accompanying ornaments of fruits, flowers, &c. are of the most exquisite workmanish. The list of succeeding sculptors, in Tuscany, is very numerous. Those of the greatest celebrity are Michael Angelo Buonarroti, no less eminent in sculpture than in painting, Baccio Bandinelli; Niccolò called l'Ibrido; Gulielmo della Porta; Jacopo Sansovino; Annibale Fontana; Benvenuto Cellini; Mont Orcoli; &c. and many others.

To these is to be added the name of Propertia di Rossi distinguished as much by her misfortunes as her talents. Her history is singularly interesting, if the circumstances related to her are authentic.

Propertia di Rossi was born at Bologna, at the close of the fifteenth century. She was not only versed in sculpture, but had reached also no common excellence in music. Her first works were carvings in wood, and on peach-stones, eleven of which were in the museum of the marquis Grassi at Bologna, each representing on one side one of the apostles, and on the other several saints. In these minute attempts having gained universal applause, she then gave a public proof of her genius in a work of considerable importance, which she finished in marble, for the front of the cathedral of St. Petronius. A bust of count Guido Pepoli was likewise greatly admired, in which grace and architecture were equally familiar to her. With all these talents, and a fame unrivalled by her sex, Propertia was most unfortunate. In early life she had been married without sympathy, her affection being the sole one which her heart was totally insensible. While her health was daily yielding to despair, she undertook the bas-relief, representing the story of Joseph and Potiphar's wife, which forms the principal subject of the work above-mentioned, belonging to the church of St. Petronius. It was at once a monument of her hopeless passion, and of her admirable skill.

The juvenile talents of Michael Angelo were displayed in the imitation, first of Donatello, and next of the antique; but he soon formed his own distinct style, consistent with the character of his native genius. This style was, like his painting, invariably grand. His anatomical knowledge was at all times conspicuous, and the display of it sometimes exceeded the just bounds. His works in various cities of Italy are numerous. The principal ones are at Rome and Florence. In the former city, they are in the church of the Most Holy Name of Jesus, in the church of St. Peter in Vicinol, (which comprises the well-known statues of Moses) and the celebrated work of the Pieta, in a chapel in St. Peter's, are worthy of the highest admiration.

At Florence, his greatest work is in the crypt of St. Lorenzo, where he has placed the statues of the dukes Lorenzo and Giugliano Medici, together with four emblematic figures of Night, Day, Twilight, and Dawn. The superior genius of this great artist established the school of sculpture in Florence; and his influence a long period, little more than imitators of his style. But although they succeeded in giving to their figures an appearance of anatomical knowledge, they were far from equalling their great predecessor in the profound conception of the principles of art. They may of course all be considered as his inferiors in a line which he had marked out for them.

With the decline of the republic of Florence, the arts also sunk into decay, or took their flight to Rome, where Algarotti became the author of a new style, by studying to unite the effects of painting with those of sculpture, and thus desiring the real intent of his art; which is to imitate the forms, not the appearances, the effects, the latter being the province of painting.

By these means sculpture assumed, under the hands of Algarotti, a mannered air, which it has never since wholly lost.

One of the most extraordinary works of Algarotti, is a large bas-relief, placed over an altar in St. Peter's church; in which he has represented St. Peter and St. Paul in the air, availing by their presence the unyielding Attila, who was advancing to the attack of Rome. The principal figures in this singular work are of the highest relief; those which are supposed less to be front in mezzo-relieve; and in the others the degree of relief is proportionally diminished, until the most distant figures are only marked with a simple line. This was considered in his time as the masterpiece of the bas-relief, and Pope Innocent the Tenth rewarded the artist with a present of 30,000 Roman crowns.

To Algarotti succeeded Lorenzo Bernini, born in 1598, who, pursuing the track which Algarotti had begun, and distinguishing himself at an early age by extraordinary matu-

rity, and equalled in his own time the other rules than the indulgence of his own fancy, and sought celebrity from the flights of caprice and extravagance. His first group was Apollo and Daphne, at the moment that the nymph begins to exhibit the change from her natural form to that of the laurel-tree. The figures are remarkably light and graceful, and the fame which this work acquired for its author was of the most excessive degree.

His later works at Rome were the celebrated chair of St. Peter's church, the monument of the pope Urban the Eighth and Alexander the Seventh, the equestrian statue of Constantine, and the fountain in the Piazza Navona.

The sculptors who followed were the imitators sometimes of one, and sometimes of the other, of these two masters.

At the same period flourished Francois de la Quessoy, called Fiammingo, unrivalled in the beautiful and tender forms of his infantine style; and of the statue of Saint Simme, he proposed to imitate the simplicity of the antique; and succeeded (says Mengs) in imitating the superficial appearance, but not the essential maxims, of the antients.

Rusconi is the last sculptor worthy of particular notice, until the appearance of Antonio Canova, a Venetian, now living, and whose productions exhibit talents of a very extraordinary rank. Many accounts of his own have been found to be in the realms of modern travellers.

Of a date very little later than the revival of art at Florence, is the commencement of its cultivation in France. While Michael Angelo was disclosing his wonderful powers at Rome, under the patronage of and at the Tenth, Jean Goujon attracted the admiration of Paris, in the reign of Francis the First, and continued to receive it in that of Henry the Second. His name is frequently placed in competition with the sculptors of the Italian school. "The works of Goujon (says a French writer) recall to our view the simple and sublime beauties of the antique." His figures were however more esteemed on the continent for the elegance of their bas-reliefs than in the French school. The Fontaine des Saints Innocens, in the Rue St. Denis at Paris, is an instance of his merit in this kind; as is also the tribute, supported by Joseph Cardinal, at the Salle des Cent Suisses at the Louvre.

Girardon, born in 1628, was at once (like the preceding artist) a sculptor and architect. His works were admired for the correctness of design, and beauty of composition; and he was said by his countrymen to have produced chefs-d'oeuvres only. The magnificent mausoleum of cardinal Richelieu in the church of the Sorbonne, the equestrian statue of Louis the Fourteenth in the Place Vendome, and numerous statues and groups in the gardens of Versailles, are testimonials of his merit.

Contemporary in age and fame with Girardon, was Puget, born at Marseilles, in 1628, and denominated by Louis the Fourteenth "the inimitable." He studied from the age of 16 to 21, in Italy, where he distinguished himself equally for the quickness of his talents, and his extraordinary dexterity in them. Soon after his return to his own country, he was invited to Paris by M. Colbert, and executed there, among other works, the particularly the groups of Milo, and Andromeda rescued by Perseus, in the park of Versailles. His works are celebrated by the French for their elevated taste, correctness of drawing, nobleness of character, and the general the happy fertility of genius, his artistic disposition of drapery for the display of the form beneath it, is much admired. Puget's reputation was at its height when Bernini became eminent at Rome; and it is not more creditable to one than to the other of these sculptors, that when Louis the Fourteenth sent an invitation to Bernini to come to Paris, that artist replied, that the king of France had no occasion for his talents, while he had such a sculptor as Puget in his dominions.

The other countries on the continent having chiefly received the rudiments of art from the two already mentioned, have cultivated a similar taste in most of their works of sculpture. In France, however, have appeared worthy of high praise: and in modern days the names of Zaner in Vienna, Sergel in Stockholm, and Kosowski in Petersburg, stand high in estimation.
It is now requisite to turn our attention to England; where, although the early period of the Reformations have left memorials of the talents of our artists, the present school of sculpture is of a very recent date. From the time of the Reformation, the art of sculpture has been almost wholly in the hands of foreign artists. Cibber, Gibbons, Rysbrack, Scheemakers, Rolli and some others, were employed on all public occasions to the exclusion of native artists.

The principal works of Cibber are the statues on the front of Bedlam, some of our kings round the Royal Exchange, and others at Chatsworth and Cambridge. He was the father of the celebrated dramatic writer Colley Cibber.

Of Grinling Gibbons is a statue in bronze of James II. now in Scotland-yard, in the Roman costume. In minute ornaments, carved in wood, Gibbons has few equals. His works of that kind are frequent; some of the best are at Lord Egremont's at Petworth, Windsor, and the duke of Norfolk's at Holm Iacey. In the tower of Trinity-college, Oxford, are other striking proofs of his genius.

Rysbrack's first appearance in England was about the year 1720, when the statues of Paris, particularly Le Pâtre, Vancele, Bouchardon, and Le Gros, enjoyed the first reputation, and his many sculptures, whose invention was exhausted in the classical subject of the royal gardens. Wherever he acquired the elements of his art, he displayed talents of a masterly artist in England. His bronze statue of King William at Bristol, and his monument of bishop Hough in Worcester-cathedral, are counted among his superior works.

Some of the busts by his hand are; John Bahlol, king of Scots, at Bahol college; Alfred, at the university, finished by Wilton; Gibbs, the architect, in the Radcliffe library; Dr. R. Friend, archbishop Boulter, and probably the busts of George I. and II. at Christchurch.

Scheemakers left many valuable works; he was particularly the monument of our monarchical bard, in Westminster-abbey, procured him the greatest celebrity.

Rolli was a native of Lyons, a city which has given birth to several French sculptors; to Cassoveux, N. Coustou, and F. Amoureaux, the contemporaries of Rolli, and with some probability his fellow-scholar under Coustou. There is a want of simplicity in the works of this artist, from which the celebrated statue of Newton at Trinity-college, Cambridge, is by no means exempt. Mr. Nightingale's monument in Westminster-abbey, says Walpole, although finely thought and well executed, is more picturesque than sepulchral.

At Christchurch are fine busts of Dr. Matthew Lee, Dr. R. Frewen, and one of the Template of Phoebus.

Since the time of the foreign artists above mentioned, many eminent English sculptors have appeared, whose works are to be found in our churches and public buildings. Wilton, Nollekens, Banks, Bacon, Piazza, Wotton, and many others, are some of the most curious names of our modern school. Wilton executed some good monuments in Westminster-abbey; Nollekens has established a fane which has stood the test of a long life of constant practice, and remains undiminished.

The characteristic merits of Banks and Bacon are thus described by Mr. Hezze, in his Inquiry into the State of The Arts in England. "Banks was among those who most zealously sought the enlargement of professional knowledge in the stores of Rome. A mind ardently roused to competition with the works of excellence which he beheld, and a hand trained from infancy to a ready expression of thoughts, unfolded the capital part to his productions an air of ancient art. "Bacon's genius was of native growth; he traversed no distant regions for improvement of his art, but drew from the researches of others sufficient food for an active and ready fancy. His conceptions were quick and sparkling, his execution polished, and his whole work characteristically graceful."

The sculpture of Flaxman denotes a chaste and correct taste, founded on the most critical study of the works of Grecian art. W. V. F. Scheemacker is an able pupil of the Venetian Canova.

England also boasts her female sculptors. The Hon. Mrs. Damer, and the illustrous a test Sibbons, have shewn distinguished talents in art.

SCURVY. See Medicine, Vol. II. p. 135, col. 2.

SCUTAGE was antiently a tax imposed on such as held lands, &c. by knight's service, towards furnishing the king's army; hence scutago habenda was a writ that lay for the king, or other lord, against tenants holding by knight's service, to serve in person, or send a sufficient man in their room, or pay a certain sum, &c.

SCUTELLARIA, scull-cap, a genus of the gymnospermia order, in the cyphemimer class of plants, and in the natural method ranking under the 40th order, paramoet. The calyx is short, tubulated, has the mouth entire, and close after flowering. There are two species in Britain, the galericulata and minor. 1. Minor. The galericulata, blue scull-cap, or hooved willow-herb. It grows on the banks of rivers and lakes, is bitter, and has a garlic smell. 2. Minor, little red scull-cap, or willow-herb. The stalks are about eight inches high; the leaves are heart-shaped, oval; the flowers are purple. It grows in fields, and on the sides of lakes. There are fourteen other species.

SCUTTLES, in a ship, square holes cut in the deck, big enough to let the body of a man, seagreng to let people down into any room below upon occasion, or from one deck to another. They are generally before the main-mast, before the king in the forecast; in the gun-room, to go down to the stern-sheets; in the round-house, to go down into the captain's cabin, when forced by the enemy in a tight aloft. There are also some smaller scuttles, which have gratings over them; and all of them have covers that people may not fall down through them in the night.

Scuttle is also a name given those little windows and long holes which are cut out in cabins to let in light.

SCYLLARUS, a genus of insects, according to Fabricius, of the order aperta; but by the Linnean system it is ranked with the genera of the order venus molluscus. The generic character is, bill large, convex, sharp-edged, channelled at the sides, hooked at the point; nostrils naked, rounded at the base of the bill; tongue car- tilaginous, split at the point; feet climbing. There is but a single species, viz. the pata- nina, which inhabits New South Wales; the size of a crow, but from the length of the tail measures 26 inches long.

SEA, in a strict sense, signifies a large portion of water almost surrounded by land, as the Baltic and Mediterranean seas; but it is now usually understood for that vast body of water which encompasses the whole earth. See OCEAN.

What proportion the supericies of the sea bears to that of the land, cannot easily be given. But that the surface of our globe is equally divided between land and water, and that accordingly calculated the supericies of the sea to be 83,490,306 square miles. But it is now well known the earth is less than half a mile thick of the earth's surface. But of him believed the existence of a vast southern continent, which captain Cook has shewn to be visionary. It was this circumstance which misled him. Accordin to the theory of that great observer, it was, that hitherto made, the surface of the sea is to the land as three to one; the ocean, therefore, extends over 125,335,798 square miles, supposing the supericies of the whole globe to be 170,931,912 square miles. To ascertain the depth of the sea is still more difficult than its supericies; both on account of the numerous experiments which it would be necessary to make, and the want of proper instruments for that purpose. Beyond a certain depth the sea has hitherto been found inanesthetic; and though several ingenious methods have been contrived to obviate this difficulty, none of them has yet been able to approach. We know in general that the depth of the sea increases gradually as we leave the shore; but if this continued beyond a certain distance, the depth in the middle of the ocean would be prodigious. Indeed the numerous islands every where scattered in the sea do not seem to present the contrary, by showing us that the bottom of the water is equal like the land; and that, so far from uniformly sinking, it sometimes rises into lofty mountains. If the depth of the sea is in proportion to the elevation of the land, as has generally been supposed, its greatest depth will not exceed five or six miles; for there is no mountain six miles perpendicular above the lev- el of the sea. The sea has never been ac- tually sounded to a greater depth than a mile and sixty-six feet; every thing beyond that therefore rests entirely upon conjecture and supposition, which ought never to be admitted to doubt. The depth of the sea can be ascertained by experiment, because, when admitted, they have too often led to false conclusions. Along the coasts, where
the depth of the sea is in general well known, it has always been found proportional to the height of the shore: when the coast is high and mountainous, the sea that washes it is deep; when the coast is low, the water is shallow. Whether this proportionality holds at a distance from the shore, experiments alone can determine.

To calculate the quantity of water contained in the sea, while its depth is unknown, is impossible. But if we suppose with Buffon that it is the greatest part of a mile, the ocean, if its superincumbent waters are 128,233,759 square miles, will contain 32,038,030,75 cubic miles of water.

Let us now endeavour to compute the quantity of water which is constantly discharged into the sea. For this purpose let us take a river whose velocity and quantity of water are known, the Po, for instance, which, according to Riccioli, is 1000 feet (or 100 perches of Boulogne) broad, ten feet deep, and runs at the rate of four miles in an hour; consequently that river discharges into the sea, in an hour, 4,800,000 cubic miles of water.

A cubic mile contains 122,000,000 cubic perches; the Po therefore will take twenty-six days to discharge a cubic mile of water into the sea. Let us now suppose that it is not very far from the truth, that the quantity of water which the sea receives from the rivers in any country is proportional to the extent of that country. The Po from its origin to its mouth traverses a country 380 square miles, and the rivers which fall into it on every side rise from sources about sixty miles distant from it. The Po, therefore, and the rivers which it receives, water a country of 45,600 square miles. Now since the whole superficies of the dry land is about 42,745,253 square miles, it follows, from our supposition, that the quantity of water discharged by all the rivers in the world, in one day, is thirty-six cubic miles. If, therefore, the sea contains 32,038,030 cubic miles of water, it would take all the rivers in the world 2439 years to discharge an equal quantity.

It may seem surprising that the sea, since it is continually receiving such an immense supply of water, does not visibly increase, and at last entirely overflow the earth. But the surprise will cease, if we consider that the rivers themselves are supplied from the sea, and that they do nothing more than carry back those waters which the ocean is continually losing from it. Dr. Halley has demonstrated that the vapours raised from the sea and transported upon land are sufficient to maintain all the rivers in the world. The simplicity of this great process is astonishing: the sea not only communicates distant countries, and renders it easy to transport the commodities of one nation to another, but its waters rising in the air descend in showers to fertilise the earth and nourish the vegetable kingdom, and collecting into rivers flowing forth, give wealth and commerce along with them, and again return to the sea to repeat the same round.

As the sea covers so great a portion of the globe, we should not doubt, by exploring its bottom, discover a vast number of interesting particulars. Unfortunately, in the great part of the ocean this has hitherto been impossible. Part, however, has been examined; and the discoveries which this examination has produced enable us to form some idea at least of the whole. The ocean, as far as we can conjecture indeed beforehand, bears a great resemblance to the surface of the dry land, being, like it, full of plains, rocks, caverns, and mountains; some of which are abrupt and almost perpendicular, while others rise with a gentle declivity, and sometimes tower above the water and form islands. Neither do the materials differ which compose the bottom of the sea and the basis of the dry land. If we dig to a considerable depth in any part of the earth, we uniformly meet with rock; the same thing holds in the sea. The strata too are of the same kind, disposed in the same manner, and form indeed but one whole. The same kind of mineral and bituminous substances are also found intermixed with these strata; and it is to them probably that the sea is indebted for its bitter taste. Over these natural and original strata an arborescent vegetation has been formed, composed of different materials in different places. It consists frequently of muddy tertiary substances firmly cemented together, sometimes of shells or coral reduced to powder, and, in some places, it is generally composed of fine sand or gravel.

The ocean differs more in saltness in different climates towards the equator than nearer the poles. This seems to arise from the difference in quantity of water evaporated, in proportion to those which fall in rain. One pound of sea-water in the Baltic yields about a quarter of an ounce of salt; near Holland half an ounce; and in the British seas about two ounces. Boyle has also observed, that in places of great depth the water is saltest at the bottom. In the voyage made towards the north pole in 1773, it was found that the sea-water at the Nore contained not quite one thirty-sixth of salt; at the broad the mouth sands not quite one thirty-second; off Flamborough Head, rather more than one twenty-ninth; off Scotland, rather less than one twenty-ninth; latitude 74°, at sea, one twenty-ninth; latitude 78°, rather less than one twenty-eighth.

The cause of the saltness of the ocean has been a subject of investigation among philosophers in almost all ages, but it still remains in great obscurity. There can be little doubt that a large quantity of saline matter existed in this globe from the creation; and, at this day, we find immense beds of salt gin, or common salt, buried in the earth, particularly in Carmania; but whether these collections have been derived from the ocean, and deposited in consequence of the evaporation of its waters in certain circumstances; or whether the ocean was itself originally fresh, and received its salt from collections of saline matter situated at its bottom, or from that brought by the influx of rivers; cannot now be ascertained.

No accurate observations on the degree of saltness of sea-water exist in particular latitudes, as those made till the present century, and it is not possible, therefore, to ascertain what was the state of the sea at any considerable distance of time, nor, consequently, whether its degree of saltness increases, decreases, or is stationary. From differences among aquatic animals, however, some of which seem adapted to salt water, and some to fresh, it is probable, that both these states of water existed from the creation of the world. We find it true, that some kinds of fish thrive only in salt water, others in fresh: some in standing pools, and others in rapid currents.

That excellent philosopher and chemist, the bishop of Lundaf, has recommended a most simple and easy mode of ascertaining the saltness of the sea in any latitude; and as the language, in point of perspicuity and correctness, cannot be improved, we take the liberty of inserting it in his own words:

"As it is not every person who can make himself expert in the use of the common means of estimating the quantity of salt contained in sea-water, I will mention a method of doing which is so easy and simple, that every common sailor may understand and practise it, and which in a few minutes of time, if we suppose the temperature of the sea to be of a degree between 32° and 42°, enables me to determine the weight of the cloth above its original weight, which is the weight of the sea-water imbibed by the cloth; and the excess of the weight of the cloth after being dried, above its original weight, is the weight of the salt retained by the cloth; and by comparing this weight with the weight of the sea-water imbibed by the cloth, we obtain the proportion of salt contained in that species of sea-water."

"Whoever undertakes to ascertain the quantity of salt, contained in sea-water, either by this or any other method, would do well to observe the state of the weather preceding the time when the salt of the sea, for the quantity of salt contained in the sea near the surface may be influenced both by the antecedent moisture and the antecedent heat of the atmosphere."

Whether the sea is saltier or not at different depths, notwithstanding Mr. Boyle’s observations before quoted, has not yet been properly ascertained; but that its temperature varies considerably in proportion to the depth we have already seen. With respect to the temperature," says bishop Watson, "of the sea at different depths, it seems reasonable enough to suppose, that in summer time it will be hotter at the surface than at any considerable depth below it, and that in winter it will be colder."

"Mr. Wales describes the instrument he made use of for trying the temperature of the sea at different depths, in the following terms: ‘On the 12th of June, I tried the sea-water at different depths connected with a wooden tube of about eighteen inches long and three inches externally. It was fitted with a valve at the bottom, and another at the top, and had a contrivance for sus-
pend the thermometer exactly in the middle of it. When it was used it was fastened to the deep sea-line, just above the lead. To this they fastened a piece of wax so that the water had a free passage through it, by means of the valves which were then both open; but the instant it began to be drawn up, both the valves closed by the pressure of the water, and of course the thermometer was brought up in a body of water of the same temperature with that it was let down to. With this instrument, which is much the same with one formerly described by Mr. Boyle, in his observations about the saltness of the sea water was fetched up from different depths, and its temperature accurately noticed, in different seasons and latitudes.

August 27, 1775, south latitude 24°. 40'. The best of the air was 32°; of the water at the surface 7°—of water from the depth of 40 fathoms 68. 47°, 29'.

December 27, 1772, south latitude 58°, 21'. The best of the air was 31°—of the water at the surface 32°—of water from the depth of 160 fathoms 33°. 47°, 29'.

In the voyage to the high northern latitudes before mentioned, they made use of a bottle to bring up water from the bottom, which is thus described:—"The bottle had some corking of the vessel, three inches thick, which was wrapped up in an oiled skin, and let into a leather purse, and the whole enclosed in a well-pitched canvas bag, firmly tied to the mouth of the bottle, so that not a drop of water could penetrate to its surface. A bit of lead shaped like a cone, with its base downwards, and a cord fixed to its small end, was put into the bottle; and a piece of valve leather, with half a dozen slips of thin bladder, were strung on the cord, which, when pulled, effectually corked the bottle on the inside. We have here put down two of the experiments which were made during that voyage.

August 4, 1773, north latitude 80°. 30'. The best of the air was 32°—of the water at the surface 36°—of water fetched up from the depth of 60 fathoms under the ice 39°. 44°, 42'.

September 4, 1773, north latitude 63°. The best of the air was 66°—of the water at the surface 55°—of water from the depth of 683 fathoms 40°.

It appears from all these experiments that, when the atmosphere was hotter than the surface of the sea, the superficial water was hotter than that at a considerable distance below it.

Sea-water may be rendered fresh by freezing, which excludes or precipitates the saline particles; or by distillation, which leaves the salt in a mass at the bottom of the vessel. Upon these principles, a mode of obtaining a supply of fresh water at sea was recommended some years ago to the admiralty, by Dr. Irving. It consisted in only adapting a tin tube of suitable dimensions to the lid of the commodore's kettle, and condensing the steam in a hogshen which served as a receiver. By this mode a supply of twenty-five gallons of fresh water per hour might be obtained from the kettle of one of our ships of war.

The sea shall be open by the laws of England, to all merchants. The main sea Beneath the low-water mark, and round England, is part of England, for there the admixture is deep.

SEALT, is either in wax, impressed with a device and attached to decals, &c. or the instrument with which the wax is impressed. Sealing of a seal, is an essential part of it; for if a writing is not sealed, it cannot be a deed.

SEALER, an officer in chancery, appointed by the lord chancellor or keeper of the great seal, to seal the writs and instruments there made in his absence.

SEALING, in architecture, the fixing a piece of wood or iron in a wall with plaster, mortar, cement, lead, and other solid binding.

SEAMEN, by various statutes, sailors having served the king for a limited time, are free to use any trade or profession, in any town of the kingdom, except in Oxford or Cambridge.

By 2 Geo. II. c. 36, male adult by 2 Geo. III. c. 31, no master of any vessel shall carry to sea any seaman, his own appren
tices excepted, without first entering into an agreement with such seaman for his wages, such agreement to be made in writing, and to the receipt whereof the seaman is to sign; but such agreement shall not be enforced by a penalty of ten pounds for each master carried to sea without such agreement, to be forfeited by the master to the use of Greenwich-hospital. This agreement is to be signed by each master within three days after entering on board such ship, and is, when executed, binding on all parties.

SEAM or SEAM of CORN, IS A MEASURE OF EIGHT BUSHELs.

SEAM of GLASS, the quantity of 120 pounds, or 24 stones each five pounds weight. The seam of wood is a horse-load.

SEAMS of a ship, are places where her planks meet and join together. There is also a kind of peculiar seam in the sowing of sails, which seam of a sail is the round seam, so called from its being round like the common seams.

SEARCHER, an officer of the customs, whose business it is to search and examine all ships outward-bound, to see whether they have any prohibited or uncustomed goods on board.

SEASIN, OR SEASING, in a ship, the name of a rope by which the boat rides by the ship's side when in the harbour, &c.

SEBATS, as the sebacid acid was, strictly speaking, unknown till the late experiments of Thénard, the description of the sebacids published by former chemists cannot be admitted as exact till they are verified by a new examination. These acids of course are unknown, if we except the few facts point
ed out by Thénard. This chemist, however, has announced his intention of publishing a detailed account of them.

1. When sebacid acid is dropped into barytes water, lime water, or straw-wax water, it does not remain in solution. Hence we learn, that the sebacin of the alkaline earths are soluble in water.

2. The alkaline sebacids are likewise soluble.
are four species: the villum, orientale, cretizum, and ceratizum. The villum, or wood-rye-grass, is distinguished by a calyx with wedge-shaped scales, and by the fringe of the glume being woolly. The glumes of the orientale are large, and the two calyces are sharp, and thick, and the glumes of the cretizum are fringed on the outside. The cretizum, or common rye, has glumes with rough fringes. It is a native of the island of Cantia, was introduced into England many ages ago. It is the only species of rye cultivated in this kingdom. There are, however, two varieties, the winter and spring rye.

The winter rye, which is larger in the grain than the spring rye, is sown in autumn at the same time with wheat, and is sometimes mixed with it; but as the rye ripens sooner than the wheat, this method must be very exceptionable. The spring rye is sown along with the oats, and usually ripens as soon as the winter rye; but the grain produced is lighter, and it is therefore seldom sown except where the autumnal crop has failed.

Rye is commonly sown on poor, dry lime-ground, where it will not thrive. By continuing to sow it on such a soil for two or three years, it will at length ripen a month earlier than that which has been raised for years on strong cold ground. Rye is commonly used for bread, or bread alone or mixed with wheat. This mixture is called medlin, and was formerly a very common crop in some parts of Britain. Mr. Marshall tells us, that the farmers in Yorkshire believe that a crop of rye will not affect the yield of barley, and that a small quantity of rye sown among wheat will prevent this destructive disease. Rye is much used for bread in some parts of Sweden and Norway by the poor people. About a century ago rye bread was also much used in England; but being made of a black kind of rye, it was of the same colour, clumsy, very disgusting, and consequently not so nourishing as wheaten.

Rye is subject to a disease which the French call crest, and the English horned rye; which sometimes happens when a very hot summer succeeds a rainy spring. According to this rye produces an irregular vegetation in the middle substance between the grain and the leaf, producing an excrecence of a brownish colour, about an inch and a half long, and two tenths of an inch broad. A bread made of this kind of rye has a nauseous acrid taste, and produces spasmodic and gorging disorders.

SECEANT, in geometry, is a line that cuts another, and divides it into two parts. See TRIGONOMETRY.

SECHUM, a genus of the syngenesa order, in the monocot class of plants; and in the natural method ranking under the 34th order, caccizizacem. The male calyx is quinquedentate and monopetalous; the corolla monopetalous; the five filaments are united in an erect tube. In the female flower the pistillum is cylindrical and crest; the stigma large, petal-shaped, and pedicelled; the pericarpium ovate, plano-convex, fleshy, and unilocular, containing one seed, which is smooth, compressed, and fleshy. Of this there is only one species, viz. the caulís, or chiloche vine. This is cultivated and grows very luxuriantly in many places in Jamaica. The vines run and spread very much. The fruit is boiled, and served up at table by way of greens; and the root of the old vine is somewhat like a yam (dioscorea), and on being boiled or roasted tastes farinaceous and wholesome.

SECOND, in geometry, chronology, &c., the sixtieth part of a prime or minute, whether of a degree, or of an hour: it is denoted by two small dots, thus (\(\cdot\)).

SECOND, in music, an interval of a joint degree. There are four kinds of seconds. The diminished second, containing four commas; the minor second, consisting of five commas; the major second, consisting of nine commas; and the redundant second, composed of a whole tone and a minor semitone.

SECONDARY, in general, something that acts as second, or in subordination to another. Secondary circles of the sphere, are circles passing through some great circle; thus the meridians and hour-circles are secondary to the equinoctial.

There are also secondaries passing through the poles of the eclipse, by means of which all stars are referred to the ecliptic.

SECONDARY, an officer who is second, or next to the chief officer; as the secondaries to the prothonotaries in the courts of B. R. and C. B.

SECRETARY, an officer who by his master's orders writes letters, dispatches, and other instruments, which he renders fit for the use of his master. Of these there are several kinds: as 1. Secretaries of state, who are officers that have under their management and direction the most important affairs of the kingdom, and are obliged constantly to attend on the king; they receive and dispatch whatever comes to their hands, either from the crown, the church, the army, private grants, pardons, dispensations, &c., as likewise petitions to the sovereign, which when passed, they dispatch according to the direction of the king in council. They have authority to commit persons for treason, and other offences against the state, as conservators of the peace, and the justice of the peace throughout the kingdom. They are members of the privy and cabinet council, which is seldom or never held without one of them being present; and as the business and correspondence in all parts of this kingdom, it is managed by the secretary for the home department. With respect to foreign affairs, the business is in the foreign office. There has been lately established a secretary of state, who is the chief officer, and must not be confounded with the secretary at war. The secretaries have each two under-secretaries, and one chief clerk. To the secretaries of state belong the custody of that seal properly called the signet, and the direction of two other offices, one called the paper-office, and the other the signet-office. See PAPER-OFFICE and SIGNET-OFFICE.

2. Secretary of an embassy, a person attendant on the diplomatic dispatches relating to the negotiation. There is a great difference between the secretary of an embassy, and the ambassador's secretary; the last being a domestic or ministerial of the former, and the first a servant or minister of the prime. 3. The secretary at war, an officer of the war-office, who has two chief clerks under him, the last of which is the secretary's messenger. There are also secretaries in most of the other offices.

SECRETION, in the animal economy, the separation of some fluid mixed with the blood by means of the glands. See PHYSIOLOGY.

SECRETIONS, morbid. In different diseases to which the annual body is subject, various fluids make their appearance which did not previously exist, at least under the forms which they assume. Thus in the dropsy the cellular substance, frequently the cavities of the head, breast, and abdomen, are filled with a whitish liquid. Where any part of the skin is irritated into a blister, the interval between the cuts and cuticle is filled with a transparent fluid; and when any part of the muscles or skin is wounded, the ulcer is soon covered with a matter called pus. See PUS.

A thin sinews exudes from cancers and cutaneous sores. The liquor of the dropsy is found upon examination to agree almost exactly with the urine. The liquor of blisters is composed also of the same constituents as the serum of blood; from 200 parts has been obtained by chemical analysis:

SECTION, in geometry, denotes a side or surface appearing of a body or figure cut by another; or the place where lines, planes, &c., cut each other.

The common section of two planes is always a right line; being the line supposed to be drawn on one plane by the section of the other, or by its entrance into it.

SECTION of a building, in architecture, is the same with its profile; or a delineation of its heights and depths raised on a plan, as if the fabric was cut asunder to discover its inside.

SECTIONS, conic, in geometry. See CONIC SECTIONS.

SECTOR, in geometry, is a part of a circle, comprehended between two radii and the arc; or it is a mixed triangle, formed by two radii and the arch of a circle.

SECTOR, See INSTRUMENTS MATHEMATICAL.

SECDUNDINES. See MIDWIFERY.

SECURIDAGA, a plant belonging to the class of daphniphyllum, and to the order of oleaceae. The calyx has three leaves, which are small, deciduous, and coloured. The corolla is papilionaceous. The vexillum, consisting of two petals, is oblong, straight, and conjoined to the carina at the base. The carina is of the same length with the ala. The legumen is ovated, unilocular, monopetalous, and ending in a legulated ala. There are three species. The erectus has an upright stem; the scandens is a climbing plant, and is a native of the West Indies.

SECUTORES, in antiquity, a kind of gladiators among the Romans, who fought against the retiarii. The scutatores were armed with a sword and buckler, to keep off the net or gauze of the retiarii, and they wore a cask on their head.

SE DEFENDENDO, in law, a plea used for him that is charged with the death of another, by alleging that he was under a necessity of doing what he did in his own defense, that the other asstitted him in such a manner, that if he had not done what he did, he must have been in hazard of his own life. But here the danger must appear so great, as to be inevitable. See Homicide.

SEDITION, among civilians, is used for a malicious commotion of the people, or an assembly of a number of citizens without lawful authority, tending to disturb the peace and order of the society. This offense is of different kinds: some seditions more immediately threatening the supreme power, and the subversion of the present constitution of the state; others tending only towards the re- dress of private grievances. Among the Romans, therefore, it was variously punished, either by banishment, or by the tending threatened greater mischief. See lib. i. Cod. de Sedition, and Mat. de Crim. lib. ii. n. 5. de Leva Majestate. In the punishment, the authors and ring-leaders were justly distinguished from those who, with less wicked intentions, joined and made part of the multitude.

The same distinction holds in the law of England and in that of Scotland. Some kinds of sedition in England amount to high treason, and come within the stat. 23 Edw. III, as levying war against the king. And several seditions are mentioned in the Scotch acts of parliament as treasonable. Hayne's Crim Law of Scotland, p. 33, 34. The law of Scotland makes riots and tumultuous assemblies a species of sedition. But the law there, as well as in England, is now chiefly regulated by the riot act, made 1 Geo. I. only it is to be observed, that the proper officers in Scotland, to make the proclamation thereby enacted, are sheriffs, stewards, and bailies of regalities, or their deputies; magistrates of royal boroughs, and all other inferior magistrates; high and petty constables, and the officers of the peace, in any county, earldom, city, or town. And in that part of the island, the punishment of the offence is any thing short of death which the judges, in their discretion, may appoint.

SEDUM, orgine, a genus of the pentaphylaceous order, in the decandria class of plants; and in the natural method ranking under the 13th order, succulenta. The calyx is quincuncal; the corolla is pentatetabolous, pointed, and spreading; there are five nectariferous squamae, or scales, at the base of the gernon. The capsules are five.

All these species of sedum are hardly hardy succulent perennials, durable in root but mostly annual in stales, &c. which, rising in spring, flower in June, July, and August, in different sorts; the flowers consisting universally of five spreading petals, generally crowning the stalks numerously in cory- bone and cyrnum bunches and spikes, appearing telescopically, and are succeeded by plenty of seeds in autumn, by which they may be propagated, also abundantly by part- ing the roots, and by slips or cuttings of the stalks in summer; in all of which methods the plants are very rapid, and spread very fast into tilled banches; being all of succulent growth, they consequently delight most in dry soils, or in any dryishy earth.

As flowering plants, they are mostly employed to embellish rock-work, ruins, and other places where the hardy flowers, or those which require a more rigorous sort of soil, are planted, either the roots or cuttings of the shoots in a little mud or any moist soil at first, placing it in the crevices, where they will soon root and fix themselves, and spread about very agreeably. For economical purposes, the rosemum and rape are cultivated in Holland and Germany, to mix with lettuce in salad. The wall-pepper is so acrid, that it blister the skin when applied externally. Taken inwardly, it excites vomiting. In scarbotic cases and quinsy, it is said to be an excellent medicin under proper management. Goats eat it; cows, horses, sheep, and swine, refuse it.

SEED. See Plants, Physiology, and Genus.

SEELING, at sea, is used in the same sense as earlier with heading: when a ship lies down constantly, or steadily on one side, the seaman say, she heels; and they call it seeling when she tumbles violently and suddenly, by the sea Forsaking her, as they call it, that the waves, planting either the roots or cuttings of the shoots in a little mud or any moist soil at first, placing it in the crevices, where they will soon root and fix themselves, and spread about very agreeably. For economical purposes, the rosemum and rape are cultivated in Holland and Germany, to mix with lettuce in salad. The wall-pepper is so acrid, that it blister the skin when applied externally. Taken inwardly, it excites vomiting. In scarbotic cases and quinsy, it is said to be an excellent medicin under proper management. Goats eat it; cows, horses, sheep, and swine, refuse it.

SEGMENT of a circle. See Geome- try.

Segment of a sphere, is a part of a sphere terminated by a portion of its surface, and a plane which cuts it off, passing some where on the sphere, and cuts the surface of the sphere. The segment of the diameter of the sphere is equal to four of its great circles; or four circles of the same diameter; so the surface of any segment is equal to four circles on a diameter equal to the chord of half the arc of the segment. So that if d denotes the diameter of the sphere, or the chord of half the circumference, and c the chord of half the arc of any other segment, also a the altitude or versed sine of the same, then,

\[ 3.1416d^2 \] is the surface of the whole sphere, and

\[ 3.1416c^2 \text{ or } 3.1416d \text{ or } 3.1416m^2 \text{ the surface of the segment.} \]

For the solid content of a segment, there are two rules usually given; viz. 1. To three times the radius of the square of its base, add the square of its height, multiply the sum by \( \pi \) the product by .5236. Or, 2. From three times the diameter of the sphere, subtract twice the height of the frus- tum; multiply the remainder by the square of the height, and the product by .5236.

That is, in symbols, the solid content is either \[ \frac{3.1416 \times 3r^2 + \pi}{4} \text{ or } = \frac{3.1416 \times 3d^2}{4} \]

That is, in symbols, the solid content is either \[ \frac{3.1416 \times 3r^2 + \pi}{4} \text{ or } = \frac{3.1416 \times 3d^2}{4} \]

SEGRERIA, in botany, a plant belonging to the class of polyandria and the order of monogynya. The calyx is petaliphiolous, the sepals are four, colored, and permanent; there is no corolla. The capsule is oblong and monospermous, the large ala terminating in small lateral sze. There are two species, the Americana and 'Mouria.

SEIGNORY, dominium, in our law, is used for a manor or lordship of a seigneur, or lord of the fief or manor.

SEIGNORAGE, signifies the right, or due belonging to a seigneur, or lord; but it is particularly used for a duty belonging to the prince, for the coming of money, called also rebours; which under our ancient kings was five shillings for every pound of gold brought in the mass to be coined, and a shilling for every pound weight of silver. At present the king claims no seignorage at all, but the crown agrees, it is said to be an excellent medicin under proper management. Goats eat it; cows, horses, sheep, and swine, refuse it.

SEINIS, in law, signifies possession. Sei- is two-fold; sein in law, and sein in fact. Sein in law, when an actual possession is taken; sein in law, when something is done which the law accounts a seinin, as an enrolment.

SEIZE, SEIZE, or SEIZE, in the sc- language, is to make fast, or bind, particularly to fasten two ropes together, with rope-yarn. The seizing of a boat is a rope tied to a ring, or little chain in the foreship of the boat, by which means it is fastened to the side of the ship.

SEIZURE, in commerce, an arrest of any merchandise, movable, or other matter, either in consequence of some law, or of some express order of the sovereign. Con- tradand goods, those fraudulently entered, or landed without entering at all, or at wrong places, are subject to seizures, arranged in seizures, among us, one half goes to the informer, and the other half to the king.

SELAGO, a genus of the angiospermae order, in the dicynemia class of plants; and in the natural method ranking under the 44th or- der, aggregate. The calyx is quincuncial: the tube of the corolla capillary, with the limb nearly equal, and a single seed. There are 20 species.

SELENITIC, in chemistry. See Sul- phate of Lime.

SELENITES, in natural history, the name of a large class of fossils, the characters of which are these: they are bodies composed of slender and single visible filaments, arranged into fine, even, and thin flakes; and those disposed into regular figures in the several dif- ferent genera, approaching to a rhomboid or hexagonal column, or a rectangular parallelo- gram; filis, like those tales, but they not traversed, or occasionally placed in a perpen- dicular direction; they are flexible in a small degree, but not at all elastic; they do not ferment with acid menstrua, but readily calci- cine in the fire. Of this class there are se-
VEN orders of bodies, and under those ten genera. The solenite of the first order are those composed of horizontal plates, and approximating to a rhomboidal form; of the second order, those composed of two columns and a triangular form; of the third are those whose filaments are scarce and arranged in plates, but which, in the whole mass, appear rather of a striated than of a radiated structure, and of the fourth order, but of no determinately angular figure; of the fifth are those formed of plates perpendicularly arranged; of the sixth are those composed of confronting plates, arranged into the figure of a star; and of the seventh are those of a complex and indeterminately figure.

The structure of the solenite of all the genera of the first order is exactly alike; they are all composed of a great number of broad flake plates or in a great measure externally resembling the flakes of the foliaceous genera; these are of the length and breadth of the whole mass; the top and bottom being each only one such plate, and those between them, in like manner, each complete and single; and the body may always be easily and evenly split up into flakes by a single blow. These flakes differ, however, extremely from the talus; for they are each composed of a number of parallel threads or filaments, which are usually disposed parallel to the sides of the body, though sometimes parallel to its ends. In many of the species they are also divided by parallel lines, placed at a considerable distance from each other, and the plates in splitting often break at these lines; these lines are not of any permanent elastic, and that they readily calcine. The structure of those of the second is the same with that of the first; but that in many of the specimens of them, the filaments of which the plates are composed run in two directions, and meet in an obtuse angle; and in the middle there is generally seen in this case a straight line running the whole length of the column; and small parcels of clay insinuating themselves into the cracks, representing it, the figure of grass so naturally, as to have deceived many into a belief that there was really an ear of grass there. The other orders consist only of single genera, the structure of each of which is a distinct and generic name. See Plate Nat. Hist. fig. 359.

S. E. L. E. U. C. I. D. E., in chronology: ara of the Seleucidae, or the Syro-Maccabonian ara, is a computation of time, commencing from the establishment of the Seleucidae, a race of Greek kings, who reigned as successors of Alexander the Great, in Syria, as the Ptolemies did in Egypt. This ara we find expressed in the book of Maccabees, and on a great number of Greek medals, struck by the cities of Syria, &c. The rabbins call it the ara of contracts, and the Arabi therik dikarum, that is, the ara of the two horns. According to the best accounts, the first year of this ara falls in the year 314 before Christ, being twelve years after Alexander's death. See SEL-TAR.

SELF, the name vulgaris of Linnaeus. The stem erect, and about eight or ten inches high. The leaves grow on foot-stalks, are ovato-oblong, slightly indented, and somewhat hairy. The bracteae are heart-shaped, opposite, and fringed. The flowers are white, or purplish, grow in dense spikes, and are terminal. This plant is perennial, grows wild in meadows and pasture-grounds, and flowers in June and July. This herb is recommended as a mild restorative and vulnerary in spittages, ulcers, and other febrile complaints, and those that arise in gargarisms against aphthae and inflamations of the fauces. Its virtues do not appear to be very great; to the taste it discovers a very slight astringency or bitterishness, which is more sensible in the flower top than the leaves.

S. E. L. I. N. U. M., a genus of the digynia order, in the pentandria class of plants; and in the natural method ranking under the 45th order, umbellate. The fruit is oval, oblong, compressed, plane, and straited in the middle; the involucrum is reduced; the petals cordate and equal. There are nine species, the sylvestre, palustre, austriacum, carulofila, chabrand, samii, spinosa, sibiricum, and decanton.

SELL, in building, is of two kinds, via ground-sell, which denotes the lowest piece of timber, in a timber building, and that on which the whole superstructure is raised; and the window-sell, called also window-sell, is the bottom pli of the window.

SELLA QUINCA. See Anatomy.

S. E. L. Z. E. R. W. A. T. E. R. See Waters, MINERAL.

SEMECARPUS, a genus of the trigyna order, in the pentandria class of plants. The corolla is quinquepalata; the drupa is heart-shaped, celiolous, and monospermon. There is but one female flower.

SEMEM, a substance prepared by nature for the reproduction and conservation of the species both in animals and plants. The peculiar liquid secreted in the testes of males, and destined for the impregnation of females, is known by the name of semen. The human semen alone has hitherto been subjected to chemical analysis. Nothing is known concerning the seminal fluid of other animals. Vauquelin published an analysis of the human semen in 1783.

Semen, when newly ejected, is evidently a mixture of two different substances: the one, fluid and milky, which is supposed to be secreted by the prostate gland; the other, which is considered as the true secretion of the testes, is a thick milky substance, in which numerous white shining filaments may be discovered. It has a slight disagreeable odour, an acid irritating taste, and its specific gravity is greater than that of water. When rubbed in a mortar it becomes frothy, and of the consistence of pomatum, in consequence of its enveloping a great number of air-bubbles. It converts paper stained with the blossoms of mallows or violets to a green colour, and consequently contains an alkali.

As the liquid cools, the mucilaginous part becomes transparent, and acquires greater consistency; but in about twenty minutes after its emission, the whole becomes perfectly liquid. This liquefaction is not owing to the absorption of moisture from the air, for it loses instead of acquiring weight during its exposure to the atmosphere; nor is it owing to the action of the air, for it takes place equally in close vessels.

Semen is insoluble in water before this spontaneous liquefaction, but afterwards it dissolves readily in it. When alcohol or oxymuratic acid is poured into this solution, a number of white flakes are precipitated. Concentrated alkales facilitate this action with water. Acids readily dissolve the semen, and the solution is not decomposed by alkales; neither is the alkaline solution decomposed by acids.

Semen decomposes no ammonia from fresh semen; but in the interval of two days煮, it loses in a moist and warm atmosphere, lime separates a great quantity from it. Consequently ammonia is formed during the exposure of semen to the air.

When oxymuratic acid is poured into semen, a number of white flakes precipitate, and the acid loses its peculiar colour. These flakes are in soluble in water, and even in acids. If the quantity of acid is sufficient, the semen acquires a yellow colour. Thus it appears that semen contains a mucilaginous substance analogous to that of the tears, which combines with absorbing oxygen. M. Vauquelin obtained from 100 parts of semen six parts of this mucilage.

When semen is exposed to the air about the temperature of 60º, it becomes gravely, covered with a transparent film; and in three or four days deposits small transparent crystals, often crossing each other in such a manner as to represent the spokes of a wheel. These crystals, when viewed through a microscope, appear to be four-sided prisms, terminated by very long four-sided pyramids. They may be separated by diluting the liquid with water, and decanting it off. They have all the properties of phosphat of lime. If, after the appearance of these crystals, the semen is still allowed to remain exposed to the atmosphere, the pellicle on its surface gradually thickens, and a number of white round bodies appear on different parts of it. These bodies also are phosphat of lime, prevented from crystallizing regularly by the too rapid abstraction of moisture. M. Vauquelin found that 100 parts of semen contain three parts of phosphat of lime. If at this period the exposure to the air becomes moist, other crystals appear in the semen, which have the properties of carbonat of soda. The evaporation does not go on to complete exsiccation, unless at the temperature of 77º, and when the air is very dry. Then, if the moisture is evaporated, the semen has lost 97 per cent of its weight; the residue is semitransparent like horn, and brittle.

When semen is kept in very moist air, at the temperature of about 77º, it acquires a yellow colour, like that of the yolk of an egg; its taste becomes acid, it exaltes the odour of putrid fish, and its surface is covered with abundance of the byssus septica.

When dried semen is exposed to heat in a crucible, it melts, acquires a brown colour, and exaltes a yellow fume, having the odour of burnt horn. When the heat is raised, the matter swells, becomes black, and gives out a strong odour of ammonia. When the odour of ammonia is dispelled, if the matter is immersed with water, an alkaline solution may be obtained, which, by evaporation, yields crystals of carbonat of soda. M. Vauquelin found that 100 parts of semen contain one part of carbonat of soda. If the part of soda is increased, there will remain only a quantity of white ash, consisting of phosphat of lime.
Thesit appears that some is composed of the following ingredients:

1. Water 6
2. Mucilage 6
3. Phosphat of lime 3
4. Soda 1
5. Mucilage

Semen ed. See Botany; and Plants, physiology of. With respect to number, plants are either furnished with one seed, as sea-plant and bistor, two, as wood-rood, and the umbelliferous plants; three, as spurge, four, as the lip-flowers of Touchwoods, and rough-leaved plants of Raya, or many, as ranunculus, azalee, and poppy. The form of seeds is likewise extremely various, being either large or small, round, oval, heart-shaped, kidney-shaped, angular, prickly, rough, hairy, wrinkled, smooth, or shining, black, white, or brown. Most seeds have only one cell or internal cavity; those of leger burdock, valerian, lamb's lettuce, carilton, sebaste, and sebastian, have two. With respect to posture, seeds are either soft, membranaceous, or of a hard bony substance; as in gnowell, umbilic, and all the nuciferous plants. In point of magnitude, seeds are either very large, as in crocus, or very small, as in campyllum, amnium, ranipong, and troughatoe.

With respect to situation, they are either dispersed promiscuously through the pulp (semen nudulenta), as in water-lily; allied to a stipe or stem of the vallaria, the seed-vessel, as in the cross-shaped and spider flowers; or placed upon a placenta or receptacle within the seed-vessel, as in tobacco and thornapple.

Seeds are said to be mixed, (semen unna) which are not contained in a cover or vessel. Such are those of the lip and compound flowers, the umbelliferous and rough-leaved plants; covered seeds (semen tecta) are contained in some vessel, whether of the capsule, pod, berry, apple, or cherry kind.

A simple seed is such as bears neither crown, wing, nor downy pap; the varieties in seeds arising from these circumstances are particular enumerated under their respective heads.

In assimilating the animal and vegetable kingdoms, Linnaeus denounces seeds the eggs of plants. The fecundity of plants is frequently the most astonishing; from a single plant or stalk of Indian Turkey wheat, are produced, in one summer, 2000 seeds; of deciduous 3000; of sun-flower 4000; of poppy 32,000; of a spike of cat-tail 10,000, and upwards; a single fruit, or seed-vessel, of tobacco, contains 1000 seeds; that of white poppy 8000. Mr. Ray relates, from experiments made by himself, that 1012 tobacco-seeds are equal in weight to one grain; and that the weight of the whole quantity of seeds in a single tobacco-plant is such as must, according to the above proportion, determine their number to be 360,000. The same author estimates the annual produce of a single stalk of spinewort to be upwards of one million of seeds.

The dissemination of plants respects the different methods or vehicles by which nature has contrived to dispense their seeds for the purpose of propagation. These by naturalists are generally reckoned four:

1. Rivers and running waters. 2. The wind.
3. Animals. 4. An elastic spring, peculiar to the seeds themselves.

1. The seeds which are carried along by rivers and torrents are frequently conveyed many hundreds of leagues from their native soil, and cast upon a very different climate, to which, however, by degrees they render themselves familiar.

2. Those which are carried by the wind are either winged, as in fir-tree, trumpet-flower, tulpin-tree, birch, arbor-vitae, medowtree, and jasmine, and some umbelliferous plants, which are covered with papules, or downy crown, as in valerian, popular, reed, succulent swallow-wort, cotton-tree, and many of the compound flowers, placed with in a winged calyx or seed-vessel, as in seacap sea, pick, dock, doreosa, ast, maple, and elm-voices, logwood, and wood; or, lastly, contained within a swelling calyx or seed-vessel, as in water-cherry, cucurbit, melis, black, and black-net, hinebor, black-sea, heart-sea, and chile-sea-thistle.

3. Many birds swallow the seeds of vane-

burr, jumaper, misseto, oats, millet, and other grasses, and void them entirely. Squire's, rats, parrots, and other animals, suffer many of the seeds which they devour to escape, and thus are the seeds of many herbs and fruits, of some of which, the pears, pears, and cherries, have been hindered from passing into a degree by some of the tribes of the people.

4. The seeds which disperse themselves by an elastic force, have that force resident either in their calyx, as in oats, and the great number of fenns; in their pappus, as in canauros; or in their capsule, as in the nuciferous plants, African spire, frank, helonella, horse-tail, basil, Malabar, cut, cumber, clemeter, and male balsam-apple.

5. The semi-cylindrical parabola, in the higher geometry, a curve which is the second order, wherein the cubes of the ordinates are as the squares of the abscissas. Its equation is 

\[ ax^2 + by = cz. \]

6. The semi-diurnal. Of any of those circles which the sun appears to perform each day revolution, beneath which is shown the horizon is called the diurnal arch, and that which is below the horizon is called the nocturnal arch, the halves of which are called the semi-diurnal and the semi-nocturnal arches.

7. See the article PARABOLO.
larger. On opening the egg, the embryo cuttle is found alive. The males are very constant, accompanying their females wherever they go, facing danger in their defence, and rescuing them intrepidly at the hazard of their own lives. The tinaceous females fly about in waves with a high noise of a cuttlefish, on being dragged out of the water, resembling the grunting of a hog. When the male is pursued by the seadragon, or other ravenous fish, he shows the danger by straitening. He spits his black liquor, sometimes the quantity of a dram, by which the water becomes black as ink, under shelter of which he baffles the pursuit of his enemy. This ink, or black liquor, has been demonstrated by M. Le Cat astonished animal, and is reserved in a particular gland. In its liquid state it resembles that of the chorioid in man, and would then communicate an indelible dye; when dry, it might be taken for the product of the black liquor in negroes dried, and made a precipitate by spirit of wine. This xatho animal, in negroes as well as in the cuttle-fish, is more abundant after death than even during life. It may serve for printing, or printing paper, and is employed in the manufacture of which the Romans used it. It is said to be an ingredient in the composition of Indian ink, mixed with rice. There are five species.

3. The large, or great cuttle, with short arms and long tentacula; the lower part of the body rhomboid and piramated, the upper thick and cylindrical. They inhabit all our seas, where having blackened the water by the effusion of their ink, they abandon it with their tail leap out of the water. They are gregarious, and switl in their motions: they take their prey by means of their arms, and embracing it, bring it to their central mouth. They adhere to the rocks, when they wish to be quiescent, by means of the concave discs that are placed along their arms.

2. The octopus, with eight arms, connected by a button beneath it. This is the polypus of Pliny, which he distinguishes from the loligo and sepia by the want of the tail and tentacula. They inhabit our seas, but are most at home in the Mediterranean. In both kinds consorts are formed of different size. The Indians affirm that some have been see two fathoms broad over their centre, and each arm nine fathoms long. When the Indians navigate their little boats, they go in dread of them; and lest these animals should fling their arms over and soak them, they never sail without an ax to cut them off. When used for food they are served up red from their own liquor, which from boiling with the adder's skin, it becomes scarlet. Barthol. says, upon cutting one of them open, so great a light broke forth, that at night, upon taking away the candle, the whole house seemed to be in a blaze.

3. The medusa, or middle cuttle, with a long, slender, cylindrical body; tail frayed, pointed, and canted on each side; two long tentacula; the body almost transparent, green, but convertible into a dirty brown; containing two pouches, which are chiefly used in colouring through fear, adapting it, chameleon-like, to that of the place they are in. The eyes are large and equal; active.

4. The sepia, or small cuttle, with a short body, rounded at the bottom; has a round fin on each side and two tentacula. They are taken off Flinthsur, but chiefly inhabit the Mediterranean.

5. The official, or official cuttle, with an ovalated body, has fins along the whole of the sides, almost meeting at the bottom, and two long tentacula. This is the one, the cuttle-bone, the shape, which was formerly used as an absorbent. The bones are frequently flung on all our shores; the animal very rarely. The conquer-eds bite off their arms, or feet, but they grow again, and the fragment is preyed upon by this type. This fish emits (in common with other species), when frightened or pursued, the black liquor which the antients supposed, by darkening the circumjacent air, concealed it from the enemy; and which they sometimes made use of instead of ink.

This animal was esteemed a delicacy among them; and is eaten even at present by the Italians. Boundalter gives us two recesses, and a direction for the drying of this fish; which may be considered as necessary to this day. Atheneus also leaves us the method of making an antique cuttle-fish sausage; and we learn from Aristotle, that those animals are in highest season when pregnant.

SEPARLE, (from sepes, a hedge), the name of the 44th or 40th of Linnaeus's Fragmenta of a natural Method, consisting of a beautiful collection of woody plants, some of which, from their size and elegance, are very proper furniture for hedges. See Box.
for that purpose: to clear it from the oil, it is put into a vessel of hot soap-water, whence being taken out, wrung, and dried, it is spun on the wheel. As to the shorter wool, it is boiled for the wool, it is only carded on the long card of serjeant, and spun over the wheel, without being scoured of its oil: and here it is to be observed, that the thread for the warp is always to be spun finer, and maintain better twisted, than that for the woof.

The word lends itself in the warp and woof being spun, and the thread reeled into skeins, that of the woof is put on spools, fit for the cavity of the shuttle; and that for the warp is wound on a kind of wooden bobbins, to fit it for warping; and when warped, it is stiffened with a size, usually made of the shreds of parchments; and when dried, put into the loom, and mounted so as to be raised by four treadles, placed under the loom, which the workman makes to act successively, equally, and alternately, one after another, with his feet; and as the threads are raised, throws the shuttle. See Weaving.

The serjeant, or being taken from the loom, is carried to the fuller, who fulls or scouring, in a tumbling mill, with fuller's-earth; and after the fulling, the knots, ends, straws, &c. sticking out on either side of the surface, are taken off with a kind of plickers or iron pincers, after which it is returned into the fulling machine, where it is worked with warm water, in which soap has been dissolved; when quite cleared, it is taken out, the knots are again pulled off; it is then put on the tenter to dry; taking care, as fast as it dries, to stretch it out, both in length and breadth, till it is brought to its just dimensions; then being taken off the tenter, it is dyed, shrunk, and pressed.

SERGEANT, or SERJEANT, at law, is the highest degree taken in that profession, as that of a doctor is in the civil law. To these serjeants, as men of great learning and experience, one court is set apart for them to plead in by themselves, which is the court of common pleas, where the common law of England is observed; yet though they have this court to themselves, they are not restrained from pleading in other courts, where the judges (who cannot be elevated to that dignity till they have taken the degree of serjeant at law) and their brethren, are held in the same great respect, next to the king's attorney and solicitor general. These are made by the king's mandate, or writ.

There are also serjeants at arms, whose office is to attend on the person of the king, to arrest persons of condition offending.

SERGEANT, or SERJEANT, in war, is an inferior officer in a company of foot, or troop of dragoons, armed with a halberd, and appointed to see discipline observed, to teach the soldiers the exercise of their arms, and to order, straighten, and form, ranks, files, &c.

SERJEANTY, signifies in law a service that cannot be due from a tenant to any lord, but to the king only; and it is either grand serjeancy or petit serjeancy.

Grand serjeancy, is a tenure whereby a person holds his land of the king by such services as he is bound to do in person; as to carry the king's banner, or his lance, or to carry his sword before him at his coronation, or to do other like services; and it is called grand serjeancy, because it is a more worthy service than the service in the common tenure of sequeance.

Petit serjeancy is where a person holds his land of the king, to furnish him yearly with some small thing towards his wars, as a horse, or a man, and is in truth, no more than some service in effect, because such tenant by his tenure ought not to go nor do any thing in his proper person.

SERIES, in general, denotes a continued succession of things in the same order, and having the same relation or connection with each other; in this sense we say, a series of emperors, kings, bishops, &c.

SERIES, in mathematics, is a number of terms, whether of numbers or quantities, increasing or decreasing in a given proportion, the doctrine of which has already been given under the article PROGRESSION.

SERIES, INFINITI, is a series consisting of an infinite number of terms, that is, to the end of which it is impossible ever to come; so that let the series becarried on to any assignable number, length, or number of terms, it can be carried on further, without end or limitation.

A number actually infinite (i.e. all whose units can be assigned, and yet is without limits) is a plain contradiction to all our ideas about number; for whatever number we can conceive, or have any proper idea of, is always determined; so that we cannot, after it may be assigned, and a greater after this; and so on, without a possibility of ever coming to an end of the addition or increase of numbers assignable; which inexhaustibility, or endlessness, in the nature of numbers, is all we can distinctly understand by the infinity of number; and therefore to say that the number of any things is infinite, is not saying that we comprehend their number, but indeed the contrary; the only thing positive in this proposition being that, the number of these things is greater than any number which we can actually conceive and assign. But then, whether in things that do really exist, it can be truly said that their number is greater than any assignable number; or, which is the same thing, that in the enumeration of their units one after another, it is impossible ever to come to an end; this proposition is true, by all men, and by all nations; we have no business in this place: for all that are concerned here to know is this certain truth; that after one determinate number we can conceive a greater, and after this a greater, and so on without end. And therefore, whether the number of any number that do or can really exist all at once, can be such that it exceeds any determinable number, or not, this is true: that there are numbers which exist, or are produced successively one after another, the number may be greater than any assignable one; because, though the number of things thus produced that does actually exist at any time is finite, yet it may be increased without end. And this is the distinct and true notion of the infinity of a series; that is, of the infinity of the number of its terms, as it is expressed in the definition.

Hence, it is plain, we cannot apply to an infinite series, the common notion of a sum, viz. a collection of several particular numbers that are joined and added together one after another; for this supposes that these particular numbers are all known and determined; whereas the terms of an infinite series cannot be all separately assigned, there being no end in the enumeration of its parts, and therefore it can have no sum in sense. But again, if we consider that the idea of an infinite series is not that of a collection of something positive and determined, in so far as we conceive the series to be actually carried on; and the idea of an inexhaustible remainder still behind, or an endless addition of terms that can be made to it one after another, this is as different from the idea of a finite series as two things can be. Hence we may conceive it as a whole of its own kind, which therefore may be said to have a total value whether that is finite or not. Now in some infinite series this value is finite or limited; that is, a number is assignable beyond which the sum of no assignable number of terms of the series can ever reach; nor indeed ever be equal to it, yet it may approach to it in such a manner as to want less than any assignable difference; and this we may call the value or sum of the series; not as being a number found by the common method of addition; but as being such a limit that if it were possible to add them all one after another, the sum would be equal to this number.

Again, in other series the value has no limit; and we may express this: by saying the sum of the series is infinite; which indeed signifies no more than that it has no determinate and assignable value; and that the series may be carried such a length that its sum, so far, shall be greater than any given number. In short, in the first case we affirm there is a sum, yet not a sum taken in the common sense; in the other case we plainly deny a determinate sum to any sense.

Theorem I. In an infinite series of numbers, increasing by an equal difference or ratio (that is, an arithmetical or geometrical increasing progression) from a given number, a term may be found greater than any assignable number.

Hence, if the series increases by differences that continually increase, or by ratios that continually increase, comparing each term to the preceding, it is manifest that the same thing must be true, as if the differences or ratios continued equal.

Theorem II. In a series decreasing in finite, to a given ratio, we can find a term less than any assignable fraction.

Hence, if the terms decrease, so as the ratios of each term to the preceding do also continually decrease, then the same thing is also true as when they continue equal.

Theor. III. The sum of an infinite series of numbers all equal, or increasing continually, by whatever differences or ratios, is infinitely great; that is, such a series has no determinate sum but grows so as to exceed any assignable number.

Demon. 1. If the terms are all equal, as \( A \); \( A \); \( A \); &c., then the sum of any finite number of them is the product of \( A \) by that number, as \( An \); but the greater \( n \) is, the greater \( An \) will be, and hence \( An \) will be still greater than any assignable number.

Secondly, suppose the series increase continually (whether it does so infinitely or limitedly), then its sum must be infinitely
great, because it would be so if the terms continued all equal, and therefore will be more so since they increase. But if we suppose the series increases infinitely, either by equal ratios or differences, or by increasing differences or ratios of each term to the preceding; then the reason of the sums being infinite will appear from the first theorem: for in such a series, a term can be found greater than any assignable number, and much more therefore the sum of that and all the preceding.

Theor. IV. The sum of an infinite series of numbers decreasing in the same ratio is a finite number, equal to the quote arising from the division of the product of the ratio and first term, by the ratio less by unity; that is, the sum of no assignable number of terms of the series can ever be equal to that quote; and yet no number less than it is equal to the value of the series, or to what we actually determine in it; so that we can carry the series so far, that the sum shall want of this quote less than any assignable difference.

Demonstration. To whatever assigned number of terms the series is carried, it is so far finite; and if the greatest term is 1, the least A, and the ratio rl, then the sum is $S = \frac{A}{1 - r}$. See Geometrical Progression.

Now, in a decreasing series from 1, the more terms we actually raise, the list of them, A, becomes the lesser, and the less it is A, rl - A is the greater, and so also is $\frac{rl}{1 - r}$. But as $\frac{rl}{1 - r} - rl - A$ is being still less than rl, therefore $\frac{rl}{1 - r} - rl - A$ is still less than $\frac{rl}{1 - r}$; that is, the sum of any assignable number of terms of the series is still less than the quote mentioned, which is $\frac{rl}{1 - r}$, and this is the first part of the theorem.

Again: The series may be actually continued so far, that $\frac{rl}{1 - r} - \frac{rl}{1 - r}$ want of $\frac{rl}{1 - r}$ less than any assignable difference; for, as the series goes on, A becomes less and less in a certain ratio, and so the series may be actually continued till A becomes less than any assignable number (by Theorem II.). Now $\frac{rl}{1 - r} - \frac{rl}{1 - r} = \frac{rl}{1 - r}$ and $\frac{rl}{1 - r}$ is less than A; therefore, let any number assigned be called N, we can carry the series so far till the last term A is less than N; and because $\frac{rl}{1 - r} - \frac{rl}{1 - r}$ wants of $\frac{rl}{1 - r}$, the difference $\frac{rl}{1 - r} - 1$, which is less than A, which is also less than N, therefore the second part of the theorem is also true, and $\frac{rl}{1 - r}$ is the true value of the series.

Solutions. The sense in which $\frac{rl}{1 - r}$ is called the sum of the series, has been sufficiently explained: to which, however, we shall add this: that whatever consequences follow from the supposition of $\frac{rl}{1 - r}$ being the true and adequate value of the series taken in all its infinite capacity, as if the whole were actually determined and added together, can never be the occasion of any assignable error in any operation or demonstration where it is used in that sense; because if it is said that it exceeds that adequate extent it is demonstrated that this excess must be less than any assignable difference, which is in effect no difference, and so the consequent error will be in effect no error; for if any error can happen from $\frac{rl}{1 - r}$ being greater than it ought to be, to represent the complete value of the infinite series, that error depends upon the excess of $\frac{rl}{1 - r}$ over that complete value; but this excess being unassignable, that consequent error must be so too; because still the less the excess is, the less will the error be that depends upon it. And for this reason we may justly enough look upon $\frac{rl}{1 - r}$ as expressing the adequate value of the infinite series. But we are farther satisfied of the reasonableness of this, by finding in facts, that a finite quantity does actually correspond with an infinite series, which happens in the case of infinite ex-}

Theorem V. In the arithmetical progression 1, 2, 3, 4, &c., the sum is to the product of the number of terms, that is, to the square of the last term, in a ratio always greater than 1:3, but approaching infinitely near it. But if the arithmetical series begins with 0, thus, 0, 1, 2, 3, 4, &c., then the sum is to the product of the last term, by the number of terms, exactly in every step as 1 to 2.

Theorem VI. Take the natural progression beginning with 0, thus, 0, 1, 2, 3, 4, &c. and take the squares of any like powers of the former series, as the squares, 0, 1, 4, 9, 16, &c. or cubes, 0, 1, 8, 27, and then again take the sum of the series of powers to any number of terms, and also multiply the last of the terms summed by the next following (reckoning always 0 for the first term) the ratio of that sum to the product mentioned grows less and less: yet so as it never can actually be equal to $\frac{1}{2}$, but approaches infinitely near to it, or within less than any assignable difference.

SERIOLES, a genus of plants belonging to the order of polygamy equalis, and to the class of syngenis, and in the natural system ranged under the 40th order, composita. The receptacle is pellucid; the calyx simple; and the papulis is somewhat plumose. There are four species: 1. The legvatis: 2. Athamia: 3. Lithopsis: 4. Ursus. The first is a native of the island of Canada, and flowers in July and August; the second is a native of Italy; and the fourth is a native of the south of Europe.

SERIPHIUM, a genus of plants belonging so since it is not the order of homogamia, and to the class of syngenis. The calyx is imbricated; the corolla is monopetalous and regular, with one oblong seed within it. There are our species, natives of the Cape of Good Hope.

SERPENS. See Astronomy.

SERPENTIES, in natural history, an order of the amphibia class, the characteristics of which are, a mouth breathing by the lungs only; body tapering; neck not distinct; jaws dilatable, not articulate; no feet, fins, or ears: motion undulatory. They are
first naked upon the earth, without thins, exposed to every injury, but frequently armed with a poison the most deadly and horrible, which is contained in the tubular fangs or teeth; the lower fangs being without the upper jaw, protruded or retracted at pleasure, and surrounded with a glabrous vesicle, by which their fatal fluid is secreted. (See Poisons.) But lest this tribe should too generally spread upon the limits of other animals, the benevolent Author of Nature has armed only about a fifth in this dreadful manner. The jaws are dilatable and not articulate, and the osseous so lax, that they can swallow an animal twice or thrice as large as the neck. There are seven genera, viz. the

Acrodontus Coccula Amphilaxa Coluber Auguis Crotalus.

The distinction of species in this numerous tribe is often peculiarly difficult. Linnaeus professed himself that an infallible criterion might be found in the number of scaly plates on the abdomen and beneath the tail; and accordingly he arranged the Systema Naturae to discriminate the species by this mark alone. Experience, however, has sufficiently shown that, though often highly useful in the investigation of these animals, it is yet by much too uncertain and variable to be permitted to stand as an established specific test.

The distinction of serpents into poisonous and innoxious can only be known by an accurate examination of their teeth; the fangs or poisoning teeth being always of a tubular structure, and calculated for the conveyance or injection of the poisonous fluid from a peculiar reservoir communicating with the fangs on each side of the head: the fangs are always situated in the anterior and external part of the upper jaw, and are generally, but not always, of much larger size than the other teeth; they are also frequently accompanied by some smaller or subsidiary fangs, supposed to supply the place of the absent ones when lost, either by age or accident. The fangs are situated in a peculiar bone, so articulated with the rest of the jaw as to elevate or depress them at the pleasure of the owner: in a quiescent state they are recumbent, with their points directed forwards or backwards; but when the animal is inclined to use them as weapons of offence, their position is altered by the peculiar mechanism of the above-mentioned bone in which they are rooted, and they become almost perpendicular.

A general rule for the determination of the existence or non-existence of these organs in any species of serpent is proposed in a paper relative to the amphibias by Dr. Gray, and published in the Philosophical Transactions for the year 1788. The fangs, according to Dr. Gray, may be distinguished with great care, and, as he believes also, with absolute certainty, by the following simple method. When it is discovered that there is something like teeth in the anterior and external part of the upper jaw, which situation he considers as the only one in which venomous serpents are ever found, let a pinch of hardy be drawn from that part of the jaw to the angle of the mouth; (which operation may, for greater certainty, be tried on each side.) If no more teeth are felt in that line, it may, he thinks, be fairly concluded, that those first discovered are teeth; and the serpent is consequently venomous: if, on the contrary, the teeth first discovered are observed not to stand alone, but to be only a part of a complete row, it may as certainly be concluded that the serpent is not venomous. This rule, however, like most others, may have its exceptions, and perhaps the most legitimate test of real fangs in a serpent is their tubular structure, which may always be easily examined. In this instance of a proper extinguisher. It is to be observed, that all serpents, whether poisonous or not, have besides the teeth, (whether fangs or simple teeth) in the sides of the upper jaw, two additional rows, which are generally much smaller than the rest, and frequently scarcely visible: the general rule, therefore, is, that all venomous serpents have only two rows of true or proper teeth in the upper jaw, and that all other serpents have three rows.

A head entirely covered with small scales is in some degree a character, but by no means an universal one, of poisonous serpents; as are also crenated scales on the head and body; these are all as furnished with a prominent middle line.

All serpents are in the habit of casting their skin at certain periods; in temperate regions annually; in the warmer perhaps more frequently. The broad winds or serpents of the temperate and cold climates also conceal themselves, during the winter, in cavities beneath the surface of the ground, or in other convenient places of retirement, and pass the winter in a state more or less approaching, in the different species, to complete torpidity. It may be added, that some serpents are viviparous, as the rattlesnake, the viper, and many others of the poisonous kind, while the common snake, and probably the major part of the innoxious serpents, are oviparous, depositing their eggs in a kind of string or chain in any warm and close situation, where they are afterwards hatched.

The broad winds or scaly plates on the bellies of serpents are termed scuta, and the smaller or divided plates beneath the tail are called squamae subcudatales, or subcaudal scales; and from these different kinds of lining the Linnaean genera of serpents are chiefly instituted.

SERPENTARIUS. See Astronomy.

SERPENTINE, a mineral found in amorphous masses, forming strata, and even entire mountains. Its fracture is splintery, sometimes conchoidal. Specific gravity 2.57 to 2.71; feels soft and almost greasy; generally emits an earthy smell when breathed. Its colours are various shades of green, yellow, red, grey, brown, and blue: commonly one or two colours form the ground, and one or more appear in spots or veins. Before the blowpipe it hardens, but does not melt. According to Mr. Chenevix it contains

SERPULCA, a genus of plants belonging to the class of monoeccus, and to the order of extrandria. The male calyx is quadrilateral, and the corolla consists of four petals. The female flowers have four parts, and the pericarpium is a tetraspermate nut. There are two species, the verticillata and repens.

SERPULCA, a genus of insects of the order verticillata. The generic character is: animal a terrella; shell univalve, tubular generally adhering to other substances; often separated internally by divisions at uncertain distances. There are 48 species.

SERRATULA, a genus of plants belonging to the class of scyphaseus, and to the order of polygamae. In the natural system it is ranged under the 49th order, composite. The calyx is subcylindrical, imbricated; the scales of it pointed, but not spinous. There are 60 species: 1. The tinctoria, grows in woods and wet pastures. It dyes cloth of an exceedingly fine yellow colour, which stands well when fixed with alum. Goats eat this plant; horses are not fond of it; cattle, oxen and sheep, leave it untouched. 2. The alpinia, or mountain saw-wort, grows on high mountains, and flowers commonly in July or August. 3. The arvensis, corn saw-wort, or way-thistle, cultivated by way-sides, and flowers in July or August. When burned, it yields good ashes for making glass or fixed alkali.

SERPOLPALUS, a genus of insects of the order anthocacti. The generic character is: antennae setaceous; fives, four, unequal; the anterior ones longer deeply serrate, composed of four joints, the last joint very large, truncate, compressed, petioliform; the posterior ones subulate; thorax margined, concealing the head, with a prominent angle on each side; head deflected; feet formed for digging. There are two species: the striatus is found on old wooden buildings in the evening in autumn.

SERTULARIA, in natural history, a genus belonging to the class of vernes, and to the order of zoophyta. The stem is radiated, fibrous, naked, and jointed; the florets are without a head, and the fruits a single joint. This genus comprehends 42 species of corallines.

SERVANT. See Master and Servant.

SERVICE, in law, is a duty which a tenant, on account of his fee, formerly owed to his lord.

SERUM, a thin transparent liquor, which makes a considerable part in the mass of blood.

The specific gravity of human blood is, at a medium, 1.037. Mr. Forcroy found the specific gravity of bullcock's blood, at the temperature of 60°, to be 1.036. The blood does not uniformly retain the same consistence in the same animal, and its consistence in different animals is very various. It is easy to see that its specific gravity must be equally various.

When blood, after being drawn from an animal, is allowed to remain for some time at rest, it very soon coagulates into a solid mass of the consistence of curdled milk. This mass gradually separates into two parts; one of which is fluid, and is called serum; the other the coagulum, has been called curd, because it retains the red corpuscles which distinguishes blood. This separation is very similar to the separation of curdled milk into curds and whey.
The proportion between the serum and the albumen in the blood varies much in different animals, and even in different parts of the same animal, in different circumstances. The most common proportion is about one part of albumen to three parts of serum; but in many cases the serum exceeds or falls short of this quantity; the limits of the ratios of these substances to each other appear, from a comparison of the conclusions of most of those who have written accurately on the subject, to be 1:1 and 1:4; but the first case must be very rare indeed.

The cause of this spontaneous decomposition of blood has not hitherto been ascertained. The coagulation takes place equally in close vessels and in the open air, whether the blood is allowed to cool, or is kept at the temperature at which it is when it issues from the animal; neither is the coagulation prevented by diluting it with water.

1. The serum is of a light greenish-yellow colour; it has the taste, smell, and feel of the blood, but its consistency is not so great. Its mean specific gravity is about 1.0297. It converts violets to a green, and therefore contains an alkali. On examination, Rouelle found that it owes this property to a portion of the albumen, the proportion of which, as far as he could determine, is about 16%; the serum coagulates, as Harvey first discovered. It coagulates also when boiling water is mixed with it; but if serum is mixed with six parts of cold water, the coagulum does not dissolve to such an extent as the coagulum of an egg. If the coagulum is cut into small pieces, a muddy fluid may be squeezed from it, which has been termed 'serosity.' After the separation of this fluid, if the residuum is carefully washed in boiling water and examined, it will be found to possess all the properties of coagulated albumen. The serum, therefore, contains a considerable proportion of albumen. Hence its coagulation by heat, and the other phenomena which albumen usually exhibits.

If serum is diluted with six times its weight of water, and then boiled to coagulate the albumen, the liquid which remains after the separation of the coagulum, if it is gently evaporated till it becomes concentrated, and then allowed to cool, assumes the form of a jelly, as was shown by Dr. Huc. Consequently it contains gelatine.

If the coagulated serum is heated in a silver vessel, the surface of the silver becomes black, being converted into a sulphuret. Hence it is evident that it contains sulphur; and Proust has ascertained that it is combined with ammonia in the state of a hydrosulphuret.

If serum is mixed with twice its weight of water, and after coagulation by heat, the albumen is separated by dilution, and the liquid slowly evaporated till it is considerably concentrated, a number of crystals are deposited when the liquid is left standing in a cool place. These crystals, first examined by Rouelle, consist of carbont of soda, muriat of soda, besides phosphat of soda and phosphat of lime. The soda exists in the blood in a caustic state, and seems to be combined with the gelatine and albumen. The carbonic acid combines with it during evaporation.

Thus it appears that the serum of the blood contains albumen, gelatine, hydrosulphuret of ammonia, soda, muriat of soda, phosphat of soda, and phosphat of lime. These compounds are not for the coagulation occasioned in the serum by acids and alcohol, and the precipitation produced by tan, acetate of lead, and other metallic salts.

With respect to the other part, the coagula of which, or that part which is sometimes called, is of a red colour, and possesses considerable consistence. Its mean specific gravity is about 1.245. If this coagulum is washed carefully by letting a small jet of water fall upon it till it takes up a watery consistence, it is partly dissolved, and partly remains upon the scarea. Thus it is separated into two portions, viz. (1.) A white, solid, elastic substance, which has all the properties of fibrina. 2. The portion held in solution by the water, which consists of the colouring matter, not however in a state of purity, for it is impossible to separate the coagulum completely from the serum.

We are indebted to Bouquet for the first precise set of experiments on this last watery solution. It is of a red colour. Bouquet found that it contained albumen and iron. Menghini had ascertained, that if blood is evaporated to dryness by a gentle heat, a quantity of iron may be separated from it by the magnet.

The quantity of iron was considerable; according to him, the blood of a healthy man contains above two ounces of it. Now, as neither the serum nor the fibrina extracted from the coagulum contains iron, it follows of course, that the water holding the colouring matter in solution must contain the whole of that metal.

This watery solution gives a green colour to syrup of violets. When exposed to the air, it gradually deposits flakes, which have the properties of albumen. When heated, a brown-coloured scum gathers on its surface. If it is evaporated to dryness, and then mixed with alcohol, a portion is dissolved; and the alcoholic solution yields by evaporation a residue, which lathers like soap in water, and tinges vegetable blue-green; the acids occasion a precipitate from its solution. This substance is a compound of albumen and soda. Thus we see that the watery solution contains albumen, iron, and soda.

Fourcroy and Vanquelin have ascertained that the iron is combined with phosphoric acid, and in the state of subphosphat of iron; thus confirming an opinion which had been maintained by Sage, and announced as a fact by the author of this work.

Nitric acid digested on this residuum dissolves a portion, which is phosphat of iron, and is precipitated white by ammonia, but assumes a red colour when treated with pure potass. This, like the demineralised water employed, phosphat of lime precipitates. By this treatment they ascertained, that of the residuum consisted of subphosphat of iron. Now phosphat of iron is soluable in acids, but insoluble in ammonia; and when treated with pure alkalies, it loses a portion of its acid, assumes a red colour, and is converted into subphosphat. Hence it is evidently the soda of the blood which reduces it to that state, or at least maintains it in that state. Subphosphat of iron readily dissolves in albumen and in serum.

When new-drawn blood is stirred briskly round with a stick, or the hand, the whole of the fibrina collects together upon the stick, and in this manner is separated from the rest of the blood. The red globules, in this case, remain behind in the serum. It is in this manner that the blood is prepared for the different purposes to which it is put, as clarifying sugar, making punch, dyes, &c. After the fibrina is thus separated, the blood no longer coagulates when allowed to remain at rest, but a spongy fleshy matter separates from it, and swims on the surface.

When blood is dried by a gentle heat, water exhalates from it, retaining a very small quantity of animal matter in solution, and consequently having the colour of blood. Blood dried in this manner being introduced into a retort and distilled, there comes over first a clear watery liquor, then carbonic acid, and carbonat of ammonia, which crystallizes in the neck of the retort; after these products there comes over a fluid oil, carbonat of hydrogen gas, and an oily substance of the consistence of butter. The watery liquor possesses the proper properties of blood; it is perfectly clear, forms a fluid from sulphat of iron a green powder; muriatic acid dissolves part of this powder, and there remains behind a little Prussian blue. Consequently this watery liquor contains both an alkaline and prussic acid. 9216 grains of dried blood being put into a large crucible, and gradually heated, at first became nearly fluid, and swelled up considerably, emitted a great many fleshy fumes of a yellowish colour, and at last took fire and burned with a white flame, evidently owing to the presence of oil. After the flames and the fumes had disappeared, a light smoke was emitted, which affected the eyes and the nose; it had the colour of prussic acid, and reddened moist paper stained with vegetable blue. At the end of six hours, when the matter had lost five-sixths of its substance, it melted anew, exhibited a purple flame on its surface, and emitted a thick smoke. This smoke collected the coagula and petals, and reddened moist paper stained with vegetable blue. But it had not the smell of prussic acid. When a quantity of it was collected and examined, it was found to possess the properties of phosphoric acid. The residuum amounted to the grains; it had a deep-black colour, and a metallic brilliancy; and its particles were attracted by the magnet. It contained no uncombined soda, though the blood itself, before combustion, contained it abundantly; but water extricated from it muriat of soda; part of the remainder was dissolved by muriatic acid, and of course was lime; there was besides a little alkalie, which evidently had been separated from the crucible. The iron had been reduced during the combustion.

Such are the properties of blood, as far as they have been hitherto ascertained by experiment. We have seen that it contains the following ingredients:

1. Water.
2. Fibrina.
3. Albumen.
5. Hydrosulphur of ammonia.
7. Subphosphat of iron.
Sesamum, oily grain, a genus of plants belonging to the class of daisyisms, and to the order of astersperma, in the natural system ranking under the 13th order, urtize. The calyx is divided into five parts. The corolla is comphomolate, the tube of which is nearly the length of the calyx, the lower lobe is divided, and very large; the border is divided into five parts, four of which are spreading and nearly equal; the fifth is the lowest and largest. There are four filaments, and the gvultinents of a fifth. The stigma is also divided, and the epidermis has four cells. There are only three species, the oriental, indipe, and luteum.

1. The orientale has ovate, obovate, entire leaves. It is an annual, and grows naturally on the coast of Mahabar and in the province of Calcuta; resting with an herbaceous four-corned stalk, two feet high, and sending out a few short side-branches. After the flowers are past, the germen turns to an oval acutely pointed capsule, with four cells, filled with oval compressed seeds, which ripen in autumn.

2. The indica, with trifoliate leaves, grows naturally in India; this is also an annual plant; the stalk rises taller than that of the former; the lower leaves are cut into three parts, which is the only difference between them. The first sort is frequently cultivated in all the eastern countries, and also in Africa, as a pulse; and of late years the seeds have been introduced into Carolina by the African negroes, which they succeed extremely well. The inhabitants of that country make an oil from the seed, which will keep good for many years, without having any rancid smell or taste; but in two years it gets quite mild; that when the warm taste of the seed, which is in the oil when first drawn, is worn off, they use it as a sal volatile, and for all the purposes of sweet oil.

The seeds of this plant are also used by the negroes; which seeds they parch over the fire, and then mix with water, and stew other ingredients with them, which makes a hearty food. Sometimes a sort of pudding is made of these seeds; the same as with wheat or rice, and is by some persons esteemed, but is rarely used for these purposes in Europe.

From nine pounds of this seed which came from Carolina, there were upwards of two quarts of oil drawn, which is as great a quantity as has been obtained from any vegetable whatever. This might occasion its being called the oily grain.

Seel, meadow-saffrine, a genus of plants belonging to the class of pentamides, and to the order of agrestima, ranging under the 43th order, unbelike. The umbels are globular; the involucre consists of one or two leaflets; the fruit is egg-shaped and streaked. There are nine species. The mountainous grows naturally in France and Italy; the glaucoma is a native of France; the seeds grow in the north of Europe; and the hyppontherium is a native of Austria.

SESSION, in law, denotes a sitting of justices in court upon their commission: as the sessions of eyer and termites. The session of the peace is a court of record held before two or more justices, when one of the justices, for the execution of the authority given them by the commission of the peace, and certain statutes and acts of parliament. The justices shall keep their sessions in every quarter of the year at least, and for three days if need be; to wit, in the first week after the feast of St. Michael, in the first week after the Epiphany, in the first week after Easter, and in the first week after St. Thomas, and oftener if need be.

Any two justices, one whereof is of the quorum, by the words of the commission of the peace, by their precept to the sheriff to summon a session for the general execution of their authority; and such session, held at any time within that quarter of a year, is a general quorum. And if such precept should bear no date, or be dated, fifteen days before the return. Nels. Inst. 33.

The sheriff shall also cause a jury to appear at such days and places as the said justices, or such two or more of them, as aforesaid, shall appoint.

There are many offenses, which, by particular statutes, belong properly to this jurisdiction, and ought to be prosecuted in this court, as the smaller misdemeanors against the public or commonwealth, not amounting to felony; and especially offenses relating to the game, highways, alehouses, bastard children, settlement and provision of the poor, vagrants, servants' wages, apprentices, and popish recusants. Some of these are proceeded upon by indictment; and others in summary way, by motion and order therefore, which shall consist, as far as the case may require, in cases where the defendant is guilty of any particular statute, may proceed to the court of king's bench by commission, and be there either quashed or confirmed.

Seventeenth, eighteenth, and nineteenth centuries and measures. In London, four justices from among the mayor, recorder, and alderman, (of which the mayor or recorder to be one) may hold a session to inquire into offenses by selling by false weights and measures, contrary to the statutes; and to receive judgments, punish the offenders, &c.

Sestercius, a silver coin in use among the Romans. See C Burrus. Some authors make two kinds of steseters: the less, called stesetinum, in the masculine gender; and the great one, called stesetinum, in the neuter, the latter containing a thousand of the former. Some, or stesetinum, was also used by the ancients for a thing containing two wholes and a half of another, as was taken for any whole or integer.

Sesuvium, a genus of plants belonging to the class of leguminosae, and to the order of consists, ranging under the 43th order of unbelike. The umbels are globular; the involucre consists of one or two leaflets; the fruit is egg-shaped and streaked. There are nine species. The mountainous grows naturally in France, and Italy; the glaucoma is a native of France; the seeds grow in the north of Europe; and the hyppontherium is a native of Austria.

Set-off, is, when the defendant acknowledges the justice of the plaintiff's demand on the one hand, but on the other sets up a demand of his own to counterbalance that of the plaintiff, either in part, or in full, as if the plaintiff sues for 10l. due on a note of hand, the defendant may set-off 9l. due to himself for merchandise sold to the plaintiff.

Black, B. 304.

The action in which a set-off is allowable upon the statutes 2 and 8 G. If. c. 22 and 24, are debt, covenant, and assumpsit, for the non-payment of money; and the demand intended to be set-off, must be such as might have been made the subject of one or other of these actions. A set-off, therefore, is never allowed in actions upon the cause, trespass, reprieve, &c. nor of a penalty, in debt on bond conditioned for the performance of covenants, &c. nor of general damages in covenant or assumpsit; but where a bond is conditioned for the payment of an annuity, a set-off may be allowed. A debt barred by the statute of limitations, cannot be set-off; and if so, the plaintiff may give the action, the defendant may reply the statute of limitations; or if 6l. in evidence, on a notice of set-off, it may be objected to at the trial. Tidd's Pract. K. B.
ing, and their proceedings are subject to the jurisdiction of the king's bench. In the making of a rate or tax, the commissioners are to assess every owner or possessor of lands in danger of receiving any damage by the water, or lands, or houses, called the slaggare, or shagrain, and much used in covering cases, books, &c.

It is imported from Constantinople, Tunis, Tripoli, Algiers, and from some parts of Poland, where it is prepared in the following manner: the skin being stretched out is first covered over with mustard-seed, which is bruised upon it; and being thus exposed to the weather for some days, it is then tanned. The best is of a brownish colour, as the white sort is the worst. It is extremely hard; yet, when steeped in water, it becomes soft and pliable; and being fashioned into covers, it really takes any colour; as red, brown, or yellow, by the fancy of the workman.

SHAKLES, in a ship, are the rings with which the ports are shut fast, by lashing the port-bar to them. There are also shackles put upon bitton-bolts, where the men have deserved corporal punishment.

SHAMBLES, among miners, a sort of niches, or landing-places, left at such distances in the adits of mines, that the shovel-men may conveniently throw the ore from shambles to shambles, till it comes to the top of the mine.

SHAMMY, or CHAMOIS LEATHER, a kind of leather dressed either in oil or tanned, and much esteemed for its softness, pliancy, and being capable of bearing soap without hurting it.

The real shammy is prepared of the skin of the chamois-goat.

The true chamois leather is counterfeited with common goat, kid, and even sheep-skin; the practice of which makes a particular profession, and consists in the Flemish chamoisery. The last is the least esteemed, yet so popular, and such vast quantities prepared, especially about Orleans, Marseilles, and Tholouse, that it may not be amiss to give the method of preparing it.

The manner of chamoisery, or of preparing sheep, goat, or kid-skins in oil, in imitation of chamois:

The skins being washed, drained, and spread out with quick-lime, on the fleshy side, are folded in two, lengthwise, the wool outwards, and laid on heaps, and so left to ferment eight days; or if they had been left to dry after faying, for fifteen days. Then they are washed out, drained, and half-dried, laid on a wooden leg or horse, the wool stripped off with a round staff for the purpose, and laid in a week pit, the lime whereof had been used before, and had lost the greatest part of its force.

After twenty-four hours they are taken out, and left to drain twenty-four more; then put into another strong pit. This done, they are taken out, drained, and put in again by turns; which begins to dispose them to take oil; and this practice they continue for six weeks in summer, or three months in winter; at the end whereof they are washed out, laid on the wooden leg, and the surface of the skin on the wood side peeled off, to render them the softer; then made into parcels, steeped a night in the river, in winter more;

stretched six or seven over one another on the wooden leg; and the knife passed strongly on the fleshy side, to take off any thing superfluous, and render the skin smooth.

Then they are dried by the fire as before in the river, and the same operation repeated on the wool side; then thrown into a tub of water with bran in it, which is brewed among the skins till the greatest part sticks to them; and then separated into distinct parts, till they swell and rise of themselves above the water.

By this means, the remains of the skin are cleaned out; they are then wrung out, hung up to dry in the open air, and thrown into the mill, with the quantity of oil necessary to fill them: the best oil is that of stok-fish.

Here they are first thrown in bundles into the river for twelve hours, then laid in the sharpener, or instrument, oil till they are well sooted; then oiled with the hand, one by one, and thus formed into parcels of four skins each, which are mixed and dried on cords a second time, then a third; then oiled again and dried.

This process is repeated as often as necessity requires; when done, if there is any moisture remaining, they are dried in a stove, and made up in parcels wrapped up in wool; after some time they are again oiled, but wrapped up again as before, till such a time as the oil seems to have lost all its force, which it ordinarily does in twenty-four hours.

The skins are then returned from the mill to the chamoiser to be scoured; which is done by putting them into a limewash of wood-ashes, working and beating them in it with their hands, and keeping them in the mill till the limes has had its effect; then wrung out, steeped in another limewash, wrung again, and this repeated till all the grease and oil is purged out. They are then half-dried, and passed over a sharpener, or instrument, oil till perpendicular in a block, which opens, softens, and makes them gentle; lastly, they are thoroughly dried and passed over the same instrument again, which finishes the preparation, and leaves them in form of chamois.

Kid and goat-skins are chamoised in the same manner as those of sheep; excepting that the hair is taken off without the use of lime, and that over the heads and legs they are opposed to the mill; when they undergo a particular preparation called ramnelling, the most delicate and diffi-

cult of all the others.

It consists in this, that as soon as brought from the mill they are steeped in a little limewash; taken out, stretched on a round wooden leg, and the hair scraped off with the knife; this makes them smooth, and in working cast a fine nap. The difficulty is in scraping them evenly.

SHANKER, or CHANCE. See MEDICINE.

SHARP, in music, a character, the power of which is to raise the note below which it is placed half a tone higher than it would be without such a preposition.

SHARPING-CORN, a customary gift of corn, said to be half a bushel for a plough-land; which the farmers pay in some parts of England to their smith, every Christmas, for sharpening their plough-irons, harrow-tines, &c.

SIIAWIA, a genius of the class and order syngecica polymer segrega. The caly-
is intricate, with five or six seeds, three interior larger; corolla five-cleft; seed one, oil-bearing. There is one species of New Zealand.

SHEATHING, in the sea language, is the casing that part of a ship which is to be under water, with fair-board of an inch thick; first-laying hair and tar, nailed together, under the boards, and then nailing them on, in order to prevent worms from eating the ship’s bottom.

SHEATS, in a ship, are ropes bent to the clew of the mizzen, lying, in the lower sails, to haul aft the clew of the sail; but, in top sails, they serve to haul home the clew of the sail close to the yard-arm.

SHEEL. See Ovis.

SHEEP. Any person who shall feloniously drive away, or feloniously steal, any sheep or lamb; or willfully kill any sheep or lamb, with a felonious intent to steal the carcasse or any part thereof; or assist or aid in committing any of the said offences, shall be guilty of felony without benefit of clergy. 13 Geo. II. c. 6.

Any person who shall apprehend and prosecute to conviction any such offender, shall have an office at his charge, for which purpose he shall have a certificate signed by the judge, before the hands of the assizes, certifying such conviction, and where the offence was committed, and that the offender was apprehended and prosecuted, by him claiming the reward; and if more than one claim it, he shall therein appoint what share shall be paid to each claimant. And on tendering such certificate to the sheriff, he shall pay the claimant for his charge, without deduction, or forfeit double, with treble costs; to be allowed in his accounts, or be repaid him out of the treasurer.

And any person who shall in the night time, maliciously and willfully main, wound, or otherwise hurt any sheep, whereby the same is not killed, shall forfeit to the party grinned treble damages, by action of trespass, or on the case.

At 26 Geo. III. c. 38, every person who shall export any live sheep or lambs, shall forfeit 3l. for every sheep or lamb, and shall suffer solitary imprisonment for three months, without bail, and until the forfeiture be paid; but not to exceed twelve months for such non-payment thereof. And all ships and vessels employed therein shall be forfeited.

SHEARING, or SHEARING, in woollen manufacture, is the cutting off with large shears the too long nap, in order to make the cloth more smooth and even. See the article CLOTH.

SHEARING, in the sea language, When a ship is not steered steadily, they say she shears, or goes shearing; or, when it anchor, she goes in and out by means of the current of the tide, they also say she shears.

SHERERS, in a ship, are two masts set across at the upper end of each other; a contrivance generally used for setting or taking out the men of a ship, where there is no hulk to do that office.

SHEFFIELDIA, a genus of plants belonging to the class of pentandria, and to the order of monogyne. The corolla is bell-shaped; the filaments are ten, of which every second is barren; the capsule consists of one cell, with two valves. There is only one species, the repens, of New Zealand.

SHEKEL, in Jewish antiquity, an ancient coin, worth 2s. 3d. sterling. See the article COIN.

Some are of opinion that the Jews had two kinds of shekels, viz. the common one, already taken notice of, and the shekel of the sanctuary; which last they made double the former, and consequently equal to 4s. 6d. but most authors make them the same; so that the shekel of the sanctuary, according to them, is only worth 2s. 3d.

SHELF, among miners, the same with what they otherwise call fast ground, or fast country; being that part of the internal structure of the earth, which they find lying even and in an orderly manner; and evidently by having retained its primitive form and situation, unmoved by the waters of the general deluge, while the circumjacent and upper strata have plainly been removed and tossed about.

SHELLS, chemically examined, are found like bones to consist of calcareous salts united to a soft animal matter; but in them the lime is united chiefly to carbonic acid, whereas in bones it is united to phosphoric acid. In shells, the predominating ingredient is carbonat of lime; but in bones it is phosphat of lime. Mr. Hatchett has divided shells into two classes. The first are usually of compact texture, resembling porcelain, and have an enamelled surface, often finely charged. These are denominated porcelainous shells; to this class belong the various species of veludo, cyprica, &c. The second class consists of shells usually covered with a strong epidermis, below which lie the shell in layers, and composed entirely of the substance well known by the name of mother of pearl. They have been distinguished by the name of mother of pearl shells. The shell of the fresh-water heloites, the turbo olivarius, are examples of such shells. The shells of the first class contain a very small portion of solid animal matter: those of the second contain a very large proportion. Hence the difference of their component parts.

Porcelainous shells, when exposed to a red heat, crackle, and lose the colour of their enamelled surface. They emit no smoke nor smell; their figure continues unaltered; their colour becomes opaque white, tinged partially with pale grey. They dissolve when fresh with effervescence in acids, and without leaving any residue; but if they have been burnt there remains always a little charcoal. The solution is transparent, gives no precipitate with ammonia or acetic of lead; of course it contains no sensible portion of phosphat or sulphat of lime. Carbonat of ammonia forms down an abundant precipitate of carbonat of lime. Porcelainous shells, then, consist of carbonat of lime cemented together with a small portion of animal matter, which is soluble in acids, and therefore resembles gelatine.

2. Mother of pearl shells when exposed to a red heat, crackle, blacken, and emit a strong foetid odour. They exfoliate, and come partly dark grey, partly a fine white. When immersed in acids they effervescence at first strongly; but gradually more and more feebly, till at last the effervescence of air-bubbles is scarcely perceptible. The acids take up only lime, and leave a number of their mucilaginous substances which still retain the form of the shell.

Some genera of sea-shells are extremely numerous, and the species under many of them are also very much so. However, they may be divided into three series or orders; the first comprehending all shells formed only of one piece, called simple or univalve shells; the second, all those shells composed of two parts or valves, under the name of bivalves; and the third, all shells composed of several parts or valves, under the name of multivalves. This method takes in all the shells hitherto known; the land, as well as the sea-shells, being all comprehended under one or other of these divisions; indeed, all the recent land-shells are univalve, but the fossil shells belong to all the three series.

SHELLS, fossil, those found buried at great depths in earth, and often immersed in the hardest stones. These fossil shells, as well as those found lying on the sea-shore, make an excellent manure, especially for cold clayey lands.

SHELLS, in the military art. See Gun- NERY.

SHERARDIA, a genus of the monogyna order, in the tetradina class of plants, and in the natural method ranking under the 47th order, stellata. The calyx is small, quadridentate; the corolla monopetalous, long, and trilobate. Their seeds are naked, and crowned with the calyx. There are three species, viz. 1. arvensis; 2. muralis; 3. triticaus.

SHERIFF. As keeper of the king’s peace, the sheriff is the first man in the county, and superior in rank to any nobleman therein, during his office. He may apprehend and commit to prison all persons who break the peace, or attempt to break it, and may bind any one in a recognizance to keep the king’s peace. He may, and is bound ex officio, to pursue and take the king’s felons, traitors, forgers, debtors, and other misdeemers, and commit them to goal for safe custody. He is also to defend his county against any of the king’s felons when they come into the land; and for this purpose, as well as for keeping the peace and pursuing felons, he may command all the people of his county to attend him; which is called the pose comitatus, or power of the county; which summons, every person above fifteen years of age, and under the degree of a peer, is bound to attend upon warning, on pain of fine and imprisonment. Yet he cannot exercise the office of a justice of the peace, for then this inconvenience would arise, that he should command himself to execute his own precepts. 1 Black. 343.

The sheriff has a jurisdiction both in criminal and civil cases; and therefore he has two courts: his for criminal cases, which is the king’s court; the other is his county court, for civil cases, and the court of the sheriff himself. 3 Salk. 329.

When the new sheriff is appointed and sworn, he ought at or before the next county court, to deliver a writ of discharge to the old sheriff; who is to set over all the prisoners in the gaol, severally by their names, (to-
SHIP, a general name for all large vessels, particularly those equipped with three masts and a bowsprit; the masts being composed of a lower-mast, top-mast, and top-gallant-mast; each of these being provided with yards, sails, &c. Ships, in general, are either employed for war or for navigation.

Straits of war are vessels properly equipped with artillery, ammunition, and all the necessary martial weapons and instruments for attack or defence. They are distinguished from each other by their several ranks or classes, called rates, as follows: ships of the first rate mount from 100 guns to 110 guns and upwards; second rate, from 90 to 98 guns; third rate, from 64 to 74 guns; fourth rate, from 30 to 60 guns; fifth rate, from 19 to 34 guns; and sixth rate, from 50 to 28 guns. Vessels carrying less than 20 guns are denominated sloops, cutters, fire-ships, and bombketches.

In Plate I. Ship-building, fig. 1, is the representation of a first-rate, with rigging, &c., the several parts of which are as follow:

Parts of the hull.

A. The cat head P. The house-holes
B. The fore chain-wales Q. The chess-trees
C. The main-chiefs R. The mizen-chains
D. The mizen-chiefs S. The stern

SHEEP, a vessel fitted up to attend on a fleet of men of war, and receive their

Ships of war are fitted out either at the expense of the state or by individuals. Those fitted out at the public expense are called king's ships, and are divided into ships of the line, frigates, sloops, &c. Ships of war fitted out by individuals are called privateers.
When the wind is cross, or nearly cross off shore, or on the opposite direction, ships will always back. This is done by the mizen-top sail, assisted, if needful, by the mizzen-staysail; such as have no mizen-top sail commonly use the main-top sail, or if it blows hard, the top-gallant-sail, or any such sail at the gaff.

In backing, a ship should always wind with a tawt cable, that it may be certain the anchor is drawn round. In case there is not a sufficiency for that purpose, the ship should be hove about.

Riding with the wind afore the beam, the yards should be braced forward; if abaft the beam, they are to be braced all aback.

If the wind is so fair that the ship will not back (which should not be attempted if, when the tide eases, the ship forges ahead, and brings the buoy on the lee quarter), she must be set ahead: if the wind is fair, and blows fresh, the utmost care and attention are necessary, as ships riding in this situation often break their sheets and come to windward of their anchors again. It should be observed, that when the ship lies in this situation, it is best to braced forward, and the fore-yards the contrary way; she will lie safe, as the buoy can be kept on the lee quarter; or suppose the helm is aport, as long as the buoy is on the fore-yards, wind the helm off, and the wind right aft, or nearly so, the starboard main and fore braces should be hauled in. This supposes the main braces to lead forward.

When the ship begins to tend to leeward, and the buoy comes on the weather-quarter, the first thing to be done is to brace about the fore-yard; and when the wind comes near the beam, set the fore-stay sail, and keep it standing until it shakes; then brace all the yards sharp forward, especially if it is likely to blow strong.

If lying in the aforesaid position, and she breaks her head, brace about the main-yard immediately; if she recovers and brings the buoy on the lee or larboard quarter, let her main-yard be again braced about; but if she comes to a shear the other way, by bringing the buoy on the other quarter, change the helm and brace the fore-yard to.

Riding leeward tide with more cable than the windward service, and expecting the ship will go to windward of her anchor, begin as soon as the tide eases to shorten in the cable. This is often hard work; but it is necessary to do it, otherwise the anchor may be fouled by the great length of cable the ship has to draw round; but even if that could be done, the cable would be damaged against the bows or cut-water. It is to be observed, that when a ship rides windward tide the cable should run down upon the short service towards the anchor, as far as will prevent the bare part touching the ship.

When the wind tends to windward and must be set ahead, hoist the fore-stay sail as soon as it will stand; and when the buoy comes on the larboard quarter, let the fore-yard be braced to the fore-yard and put the helm alee; for till then the helm must be kept aweather and the yards full.

When the ship rides leeward tide, and the wind increases, care should be taken to give her more cable in time, otherwise the anchor may start, and probably it will be troublesome to get her right up again; and this care is the more necessary when the ship rides in the hause of another ship. Previous to giving a long service it is usual to take a weather-linet, that is, a turn of the cable over and then lowering away the ship will be under command. The service ought to be greased, which will prevent its chafing in the hause.

If the Gale continues to increase, the topsmasts should be struck in time; but the fore-yard should remain till it be lowered down, in case of parting the foresail may be ready to be set. At such times there should be more on deck than the common anchor-watch, that no accident may happen from instant failure of aseye.

In a tide-way a second anchor should never be let go but when absolutely necessary; for a ship will sometimes ride easier and safer, especially if the sea runs high, with a very long scope of cable and one anchor, than with less length and two cables; however, it is advisable, as a preventive, when ships have not room to drive, and the night is dark, to let fall a second anchor under foot, with a range of cable along the deck. This is not thought necessary to be done if the deep-sea lead should be thrown overboard, and the line frequently handed by the watch, that they may be assured she rides fast.

If at any time the anchor-watch, presuming on their own knowledge, should wind the ship, or suffer her to break her sheer without calling the mate, he should immediately, or the very first opportunity, oblige the crew to brave the anchor in sight; which will prevent the commission of the like fault again; for, besides the share of trouble the watch will have, the rest of the crew will blame them for neglecting their duty.

Prudent mates seldom lie a week in a roadstead without having their anchor in sight; even though they have not the least suspicion of its being foul. There are other reasons why the anchor should be looked at; sometimes the cable receives damage by overwearing rakes or anchoring too long, or being lost, or iron rocks or stones; and it is often necessary to trip the anchor, in order to take a clearer birth, which should be done as often as any ship brings up too near.

SHIP-BUILDING may be defined, the manner of constructing ships, or the work itself, as distinguished from naval architecture, which may be considered as the theory or art of delineating ships on a plane.

Art of delineating ships on a plane.

All edifices, whether civil or military, are known to be erected in consequence of certain established plans, which have been preserved altered or improved till they have arrived at their destined point of perfection. The construction of ships appears also to require at least as much correctness and precision as the buildings which are founded upon terra firma; it is therefore absolutely necessary that the mechanical skill of the shipwright should be assisted by plans and sections, which have been drawn with all possible exactness, examined by proper calculations, and submitted to the most accurate scrutiny.

Naval architecture may be distinguished
SHIP-BUILDING.

637

into three principal parts. 1. To give the ship such an exterior form as may be most suitable to the service for which she is designed. 2. To give the various pieces of a ship their proper figure, to assemble and unite them to a framework, so that by their combination and disposition they may form a solid fabric, sufficient to answer all the purposes for which it is intended. 3. To provide convenient accommodations for the officers and crew, as well as suitable apartments for the cargo, furniture, provisions, artillery, and ammunition.

The exterior figure of a ship may be divided into the bottom and upper works. The bottom, or quick-work, contains what is termed the hold, and which is under water when the ship is laden. The upper works, called also the dead-work, comprehend that part which is usually above the water when the ship is laden. The figure of the bottom is therefore determined by the qualities which are necessary for the vessel, and conformable to the service for which she is proposed.

The limits of our design will not admit of a minute description and enumeration of all the pieces of timber which enter into the construction of a ship, nor of a particular description of every angle and union, or the manner in which they reciprocally contribute to the solidity of those floating cities.

It is usual among shipwrights to delineate three several draughts. 1. The whole length of the ship is represented according to a side view, perpendicular to the keel, and is termed the plane of elevation, or sheer draught. Plate II. fig. 10, 11, the name exhibited according to an end view, and stripped of her planks, so as to present the outlines of the principal timbers; and this is properly termed the plane of projection, or the vertical plane of the timbers (fig. 11), because it shows the projection of their frames relatively to each other. 2. It is not sufficient to have the vertical curves of the bottom in different planes, for a distinct idea of the horizontal curves is equally necessary, as obtained by the horizontal lines, traced upon what is called the horizontal plane (fig. 11). In this draught the curves of the transoms, called the round- aft, are also marked, and sometimes the breadth and thickness of the timbers.

The plane of elevation (fig. 10), determines the length and depth of the keel; the difference of the draughts of water; the length and projection, or rake, of the stem and stern-post; the position of the midship-frame upon the keel, together with that of the principal upper deck abreast and abaft; the loadwater line; the water; the dimensions and situations of the gun-ports; the projection of the rails of the head and stern-galley; with the stations of the masts and channels.

This draught, however, conveys no idea of the vertical curve of the ribs or timbers; for as their projection will be only represented in a plane elevated upon the length of the keel, they will appear as different straight lines. To perceive these curves accurately, they must be regarded in another point of view; which will represent their projection upon a vertical plane, supposed to cut the keel at right angles in the place where the ship is broadest.

For, as all ships are broadest near the middle of their length than towards the extremities, it is evident that the timbers are more extended in proportion. The most capacious parts of the ship represent the midship frame; and upon the area of this frame is delineated the projection of all the others.

Thus the plane of projection limits the different breadths of a ship in various points of her length, and exhibits the outline of the timbers respectively to each other as they are erected upon the keel. Accordingly, this draught ought to present a variety of sections of the ship in different places of her length, and always perpendicular to the surface of the water; so that the eye of the observer, when placed in what may be properly termed the axis of the ship, may perceive the several sections at one glance; that is to say, when looking full on the stem from before the ship, he shall discover the forestimbers; and when looking from behind, directly to the stern, he shall perceive the form of the after-timbers.

To form a just idea of this plane, therefore, we ought to suppose a ship resting upon the bottom, with the stern in the same situation above the water, and the prow directed to the water. Thus a variety of black vertical lines may be drawn at equal distances upon the bottom, which is white, to form different outlines of the ship corresponding to the timbers within. It is to be observed, that the fashion of the inferior timbers must conform to the figure of the midship-frame, which is placed in the fullest part of the ship; and as the planes of all their timbers diminish in a certain progression as they approach the stern and stem, they are properly delineated upon the plane of the midship-frame, which also represents the depth of the keel and length of the midship-beam.

As the two sides of a ship ought to be exactly alike, it is judged sufficient to represent the sections of the fore-part of the ship on the left side, and those in the after-part on the right side, so as to perceive all the sections, as well afore as abaft, upon one plane. See the Plate, fig. 12.

However necessary it may be to understand precisely the vertical curves of the bottom, it is far less necessary than to have a just idea of those which are horizontal.

The horizontal or floor-plane is that upon which the whole frame is erected, and will be more clearly understood by previously describing the water-lines and ribs of which it is composed.

When a ship floats upon the stream, it is evident that her upper works will be separated from the bottom by the surface of the water, which will accordingly describe an imaginary horizontal line upon the bottom from the stem to the stern-post.

The most elevated of those lines is termed the load-water line, which is supposed to be drawn by the surface of the water on the upper part of the bottom, when she is sufficiently laden for her draught. For it we suppose this surface a rule, and thereby describe a corresponding black line along the vessel's bottom, that line will be distinguished upon the bottom, which is white, and represent what is called the load-water line.

If the ship is lightened of any part of her lading, and preserves the same difference in her draught of water at the two ends; or, what is the same thing, if she is lightened so as to preserve the same equilibrium of the keel with regard to the surface of the water, it is evident that the water will rise higher out of the water; so that the load-water line may be elevated above it; and another black line may be delineated upon the bottom, close to the surface of the water, which will exhibit a second water-line parallel to the first, but nearer the keel in proportion to the number of feet which the ship has risen.

Thus by lightening a ship gradually, and at the same time preserving the direction of her keel, or the angle which the keel makes with the surface of the water, a variety of water-lines may be drawn parallel to each other, and to the load-water line.

The ribs are likewise of great utility in ship-building; they are narrow and flexible planks placed on the bottom at different heights, so as to form a sort of mould for stationing the inferior timbers between the principal ones. They  differ from the water-lines, inasmuch as the latter is a line curve, which is horizontal; whereas the ribs, besides their horizontal one, have a vertical curve. To convey a just idea of these curves, which cannot be represented on the draughts at their true magnitude, or an oblique section of the ship's length, it will be necessary to have recourse to two planes; that of the elevation, which exhibits their vertical curve; and to the floor-plane, upon which the horizontal curve is expressed.

These different lines are extremely useful in exhibiting the various curves of a ship's bottom, that, as they are gradually diminished, their uniformity or irregularity may be discovered by the skilful artist.

The qualities required in a ship ought to be determined by the figure of the bottom. A ship of war, therefore, should be able to sail swiftly, and carry her lower tier of guns sufficiently out of the water; otherwise a small ship will have the advantage of a large one, inasmuch as the latter cannot open her lower battery in a fresh side-wind without being exposed to extreme danger by receiving a quantity of water between decks. Merchant-ship ought to contain a large cargo of merchant-goods, and be navigated with few hands; and both should be able to carry sail firmly, steer well, drive little to leeward, and sustain the shocks of the sea without being violently strained.

The first thing to be established in the draught of a ship, is her length; and as a ship of war, according to her rate, is furnished with a certain number of cannon, which are placed in battery on her decks, it is necessary that a sufficient distance should be left between their ports to work the guns with facility; and particularly to leave space enough between the foremost guns and the stern, and between the aftmost gun and the stern-post on each side, on account of the arching or inward curve of the ship toward her extremities.

When the length of a ship is determined, it is usual to fix her breadth by the dimensions of the midship-beam. On this occasion the shipwrights, for the most part, are conducted by rules founded on their own observation; for, having remarked, that some vessels, which by repeated experience have
been found to answer all the purposes of navigation, have a certain breadth in proportion to their length, they have inferred that it would be improper to depart from this proportion; but no other ships have been constructed with different breadth without which a ship would be incapable of being driven to a ship relatively with her length, whilst each one produces a reason and experience in support of his own standard. Those who would diminish the breadth, allege: 1. That a narrow vessel meets with less resistance in passing through the water. 2dly. That by increasing the length she will drive less to leeward. 3dly. That according to this principle, the water-lines will be more conveniently formed to divide the fluid. 4thly. That a long and narrow ship will require less sail to advance quickly; that her masts will be lower, and her rigging lighter, and, by consequence, the seams less fatigued with more rigorous sail to the wind. Those of the contrary, who would enlarge the breadth, pretend, 1st. That this form is better fitted to preserve a good battery of guns. 2dly. That there will be more room to work the guns conveniently. 3dly. That by having more sail, the ship will be enabled to run faster, or, that this quality will at least overbalance the advantage which the others have of more easily dividing the fluid. 4thly. That being broader and more water-line, or place where the surface of the water describes a line round the bottom, they will admit of being very narrow on the floor, particularly towards the extremities. And, 5thly. That a broad vessel will more readily rise under the waves than a narrow one. From such opposite principles has resulted that variety of standards adopted by different shipwrights.

It has been remarked above, that a ship of war must carry her lower tier of cannon high enough above the water, otherwise a great ship which cannot open her lower battery, when sailing with a fresh side-wind, may be taken by a small one that can make use of the same advantage.

A ship should be duly poised, so as not to dive or pitch heavily, but go smooth and easy through the water, rising to the waves when they run high, and the ship has reduced her sail to the storm; otherwise they will break aback, and stran the decks or carry away the boats: the masts are likewise in great danger from the same cause.

A ship should sail well when large and before the wind, but chiefly close hauled, or with a side-wind, and her sails sharp trimmed, and the main gaff full off to the larder.

Now, the great difficulty lies in uniting so many different qualities in one ship, which seems to be nearly impossible; the whole art, therefore, consists in forming the body in such a manner that none of these qualities should be absolutely denied, and giving a preference to that which is chiefly required in the particular service for which the vessel is designed. We shall briefly show the possibility of uniting them all in one ship, that can be equally driven in long, and highly felt by the wind. If it happens otherwise, the fault must lie in the builder, who has not applied himself to study the fundamental rules and principles of his art.

To make a ship carry a good sail. A flat fore-timber, and somewhat long, or the lower futtock pretty round, a straight upper futtock, and the spar-timber to throw the breadth out aloft, in order to carry her main and breadth as high as the lower deck. Now, if the rigging is well adapted to such a body, and the upper works lightened as much as possible, so that they all consent to lower the centre of gravity, there will be no room to doubt of her carrying a good sail.

To make a ship steer well, and answer the horn quickly. If the fashion-pieces are well formed, the tack, or spreading parts under the stern, carried pretty high, the midship-frame well forward, a considerable difference in the draught of water abaft more than aloft, a great rake forward and oblong, a snug quarter-deck and fore-castle; all these will make a ship steer well. A ship which sails well is very easily driven.

To make a ship carry her guns well out of the water. A long floor-timber, and not of great rising; a very full midship-frame, and low tack, with light upper works.

To make a ship go smoothly through the water without pitching hard. A long keel, a long floor, not to rise too high aloft and abaft; but the area or space continued in the fore-body, according to the respective weights they are to carry; all these are necessary to make a ship go smoothly through the water.

To make a ship keep a good wind, and drive lickety to the leeward. A good length of keel, but not too long; and pretty deep in the hold, which will occasion her to have a short floor-timber, and a great rising. As such a ship will meet with great resistance in the water going over the breadthside, and little when going ahead, she will not fall much to the leeward.

Now, some builders imagine it is impossible to make a ship carry her guns well, bear a good sail, and be a prime sailer, because it would require a very full bottom to gain the first two; whereas, a sharp ship will answer better for the latter; but when it is considered that a full ship will carry a great deal more sail than a sharp one, a good artist may so form the body as to have all these three good qualities, and also steer well.

Without attempting to describe the pieces of which a ship is composed, and to explain the principal draughts used in the construction thereof, we observe that in vessels of war, the general dimensions are established by authority of officers appointed by the government to superintend the building of ships. In the merchant-service, the extreme breadth, lengths of keel, depth in the hold, height between decks and abaft, are agreed on by contrast; and from these dimensions the shipwright is to form a draught suitable to the trade for which the ship is designed. In projecting the draught of a vessel of war, the first article to be considered is her length. As all ships are much longer above than below, it is also necessary to distinguish the precise part of her height from which her length is taken; this is usually the lower gun-deck, or the main water-line. It has been already observed, that water-lines are described longitudinally on a ship's bottom by the surface of the water in which she floats; and that the line which determines her depth under the water, is usually termed the load water-line. In this draught it will be proper to consider it necessary to leave sufficient distance between the water-line and the deck, to contain the effects of the faults of construction.

The next object is to establish the breadth of the midship-beam. Although there is great difference of opinion about proportioning the breadth to the length, yet it is most admitted to be necessary to have ships of the same rate. After the dimensions of the breadth and length are determined, the depth of the hold must be fixed, which is generally half the breadth; but the breadth of the ship should be considered on this occasion; for a flat floor will require less depth in the hold than a sharp one. The distance between the decks must also be settled.

We may then proceed to fix the length of the keel, by which we shall be enabled to judge of the rake of the stem and stern-post. The rake is known to be the projection of the ship at the height of the stem and stern-post, and the ends of the keel above and abaft, or the angle which they may be increased as the fabric rises. To this we may also add the height of the stem and wing-transom. After these dimensions are settled, the timbers may be considered which form the sides of the ship. A frame of timbers, which appears to be one continued piece, is composed of one floor-timber, whose arms branch outward to both sides of the ship; two or three futtocks, and a top-timber. The futtocks are connected to the upper arms of the floor-timbers, and cause the frame to be prolonged the timber in a vertical direction; and the top-timbers are placed at the upper part of the futtocks for the same purpose; all these being united, and secured by crossbars, or a circular inclosure, which is called a frame of timbers. And as a ship is much broader at the middle than at the extremities, the arms of the floor-timber will form a very acute angle at the extreme breadth; but this is decreased by the dimensions of the timbers from the midship-frame, so that the foremost and aftermost ones will form a very acute angle. Floor-timbers of the latter sort are usually called crutches.

Shipwrights differ extremely in determining the station of the midship-frame; some placing it at the middle of the ship's length, others further forward. They who place it before the middle, allege, that if a ship is full forwards, she will meet with no resistance after she has opened a column of water; and that the water so discharged will easily unite abaft, and by that means force the ship forward; besides having more power on the rudder, in proportion to its distance from the centrefore, the motions of the vessel cause the form of shives, which should be the most advantageous for dividing the fluid.

When the rising of the midship floor-timber is decided, we may then proceed to describe the rising line of the floor, on the stem-post above the station of the midship-frame; some placing it at the middle of the ship's length, others forward. They who place it at the middle of the ship, allege, that if a ship is full forwards, she will meet with no resistance after she has opened a column of water; and that the water so discharged will easily unite abaft, and by that means force the ship forward; besides having more power on the rudder, in proportion to its distance from the centrefore, the motions of the vessel cause the form of shives, which should be the most advantageous for dividing the fluid.

The height of the lower-deck is the next thing to be considered; it is determined in the middle by the depth of the hold; and some builders make it no higher than the stem; but they raise it abaft as much above its height in the middle, as the load water-
SHIP-BUILDING

mask, or of draught of water abaft, exceeds that at
take with regard to the height between decks, it is altogether arbitrary, and must be
determined by the rate of the ship and the service she is designed for.

It is also necessary to remember the sheer of the wales and to give them a proper hang-
ing; because the beauty and stateliness of a ship greatly depend upon their figure and curve, which, if properly drawn, will make her appear airy and graceful and the water line plain.

We come now to consider the upper works and all that above water, called the deck-
work: and here the ship must be narrower so that all the weight lying above the low water-line, will thereby be brought nearer the middle of the breadth, and of course the ship will be less strained by the working of her guns, &c.

But although some advantages are acquired by diminishing the breadth, above water, we must be careful not to narrow her too much; as there must be sufficient room left on the upper deck for the quarter gallery, the direction of the mast, etc. The stern, the quarter gallery with its windows, ED, the quarter galleries, which limit the stern on each side, F, the taffrail, or upper piece of the stern, FG, profile of the stern with its galleries, H, the gun-port, I, the channel, K, the winch-pan, KG, the counter, LB, the deck-pan. MNO, the first, second, and third transoms, of which O K is the third or lowest, OL, the deck-piece, L, the fashion-piece, having its breadth carried aft nearly towards the stern. QR, the main sked, for holding in the keels clear of the ship's side. SR, the main wale, with its sheer at the head and curved parallel to the main-wale. ST, the sheer parallel to the wales. T, the rudder. A, P, the rake of the stern. YW, the waist rail. P, P, the drip rails abaft and at the drift rails forward. TUC, the water-line, XX, the rails of the head. Y, the knee of the head, or cutwater. ZZ, the checks of the head, A, the cathead. MG, C, the rising line of the floor. K C, the cutting-down line, which limits the thickness of all the floor-timbers, and likewise the height of the dead wood abaft and stern. U, UW, the midship-frame. a, b, c, d, e, f, g, h, the frames or timbers in the fore body of the ship, that is, before the midship-frame. I.

As the eye of a spectator is supposed in this projection to view the ship's side in a line perpendicular to the plane of elevation, it is evident that the convexity of that side of a cylinder of globes, when viewed at a great distance; and that the frames will consequently be represented by straight lines, except the fashion-piece abaft and the knuckle-timber forward.

It has been already observed, that the plane of projection may be defined a vertical delineation of the curves of the timbers upon the plane of the midship-frame, which is perpendicular to that of the elevation. It is necessary to observe here, that the various methods by which these timbers are described, are equally mechanical and arbitrary. In the latter sense, they are calculated to make a ship fuller or narrower, according to the service for which she is designed; and in the former they are drawn according to those rules which the artist has been implicitly taught to follow, or which his fancy or judgment has esteemed the most accurate and convenient. They are generally composed of several arches of a circle, connected together by moulds framed for that purpose.

The radii of those arches, therefore, are of different lengths, according to the breadth of the ship in the place where such arches are swept; and they are all based on the plane of projection either by horizontal or perpendicular lines; the radii of the breadth-sweeps being always in the former, and the radii of the floor-sweeps in the latter direction. These arches are divided by a third, which coincides with both without intersecting either. The curve of the top-timber is either formed by a mould which corresponds to the arch of the breadth-sweep, or by another sweep, whose centre and radius are without the plane of projection. The breadth of the ship at every top-timber, is limited by a horizontal line drawn on the floor-plane, called the half-breadth of the top timbers. The extreme breadth is also determined by another horizontal line on the floor-plane; and the lines of half-breadth are thus mutually transferable from the projection and floor-planes to each other.

The necessary data by which the curves of the timbers are determined, then, are the perpendicular height from the midship-frame to the main or principal breadth; and the top breadth; for as a ship is much broader near the middle of her length than towards the end, so she is broader in the middle of her height than above and below; and this latter difference of breadth is contained throughout every point of her length. The main breadth of each frame of timbers, is therefore the ship's breadth nearly in the middle of her height in that part, and the top breadth is the line of her breadth near the upper ends of each timber. It has been already observed, that as both sides of a ship are alike, the arches only draw one side, from which both sides of the ship are copied. Therefore the timbers abaft the midship-frame are exhibited on one side of the plane of projection, and the timbers before it on the other.

Plane of projection.

Fig. 12. A, the keel. BC, the line which expresses the upper edge of the keel, from which the height of each timber and height of its different breadths are measured. BD, and CE, perpendiculars based on the line BC, to limit the ship's extreme breadth and height and breadth abaft, by other words, to limit the breadth and height of the midship-

frame. AF, a perpendicular erected from the middle of the keel to intersect the line of the ship's breadth in two equal parts. P, G, the half-breadth line of the aftmost top-tim-
ber; being the uppermost horizontal line in this figure.

The seven lines parallel to and immediately under this, on the right side of the line AF, are all top-timber half-breadths, where the midship-frame; the lowest of which coincides with the horizontal line DE.

The parallel horizontal lines nearly opposite to these, on the left side of the line AF represent the top-timber half-breadths in the fore-body, or the half-breadths of the top-timbers before the midship-frame.

G, H, I, Q, R, S, T, the radii of the breadth-sweeps abaft the midship-frame; those of the breadth sweeps in the fore-body, or before the midship-frame, are directly opposite on the right side.

G, A, show the midship-frame, from the extreme breadth downwards, 1, 2, 3, 5, 6, 7, 8, 9, the outlines of the upper deck, or the midship-frame, in different parts of the height, K, L, M, N, O, the outlines of the timbers before the midship-frame, in different parts of their height, K being the foremost or knuckle-timber. K, L, the wing-timbers, with a dotted line, the figure of the fashion-piece, L, the deck-transom, parallel to and under the wing timbers. MNO, the lower transoms, of which O K is the third and lowest. m, n, p, q, r, s, the radii of the floor-sweeps, sbnt before the midship-frame; those before the midship-frame are on the opposite side of the line AF, to which they are all parallel.

1st R, 2d R, 3d R, 4th R, the diagonal ribs abaft the midship: t, u, x, y, the same ribs expressed in the forebody.

It has been remarked, above, that the horizontal plane is composed of water-lines and ribs; also it contains the main and top-timber-breadths, or longitudinal lines by which the main-breadth and top-timbers are limited in every point of the ship's length. The horizontal lines upon the deck-pan and timbers, and the ordinates drawn from them, are the lines of the main-breadth, the main and top-timbers abaft the midship-frame are limited by every point of the ship's length. The horizontal and vertical lines on the deck-pan and timbers, and the ordinates drawn from them, are the lines of the main-breadth, the main and top-timbers abaft the midship-frame are limited by the length of the ship.

Horizontal Plane.

RAC, Fig. 11, the line of the ship's length, passing through the middle of the stem and stern-post. C, the upper end of the stem. B, the length of the rake abaft. DWX, the top-timber-breadth line, or the line which limits the breadth of each top-timber. DEF, the breadth of the aftermost timbers. BS, the wing-transom. BIL, the horizontal curve of the deck-transom. AE, the top-timber-breadth line, or the line which limits the breadth of each top-timber. AM, the horizonal curve of the second transom; it is prolonged into a water-line, N S. O, the horizontal curve of the third transom, which is also prolonged into another transom, O N, U, Q, to O P, the plane of the fashion-piece, as con-
SHIP-BUILDING.

Of constructing ships.

The pieces by which this complicated machine, a ship, is framed, are joined together in various pieces, by scarfing, rabiting, tenoning, and dovetailing. Thus the plane of elevation of the timbers of the midship-frame, the keel, and the floor-timber, are mutually transferred, and thus the height of the midship-frame of the ship is increased.

During the construction of a ship, she shall be supported in the dock, or upon a wharf, by a number of solid blocks of timber placed at equal distance from, and parallel to, each other, and thus secured to the boat-blocks, as shown by the letter "\(X\)," the figure of the upper rail of the head, \(Y\), the projection of the knee of the head.

The third horizontal riband is marked on the plate, \(a\), \(a\), the projection of the cut-head.

Thus, we have endeavoured briefly to explain the nature and uses of the principal draughts used in the construction of a ship, which also correspond with each other in the dimensions of length, breadth, and depth. Thus, the plane of elevation of the timbers in the floor-plane, and that of the projection, are mutually transferable, and the height of the timbers in the projection conforms to their height in the elevation. Thus, let it be required to transfer the height of the wing-transom from the elevation to the projection.

Extend the compasses from the point \(K\), in the elevation, down to the dotted line prolonged from the upper edge of the keel, and setting the other foot in the point \(p\), then shall the line \(K\) be the perpendicular height, in the wing-transom, transfer the line from the midship-frame to the elevation, to the point \(K\) in the perpendicular AF, then will \(AK\) be the height of the wing-transom in the plane of projection; and thus the height of all the transoms may be laid from the form upon the latter.

Again: Let it be required to transfer the main-breadth of the midship-frame from the projection to the horizontal plane: Set one foot of the compasses in the point \(a\) on the perpendicular \(CE\), and extend the other along the main-breadth sweep \(G\), till it touches the perpendicular \(AP\) parallel to \(CE\); by this distance upon the horizontal plane from the point \(a\) in the line of the ship's length, \(BAC\), along the plane of the midship-frame to the point \(a\); so shall the line \(G\) will be the breadth of the midship-frame on the horizontal plane.

Thus also the top-timber-breadth, or the depth of the ship by-drawer from the midship of the ship's breadth, may be in the same manner transferred, by extending the compasses from the line \(BAC\), in the horizontal plane, to the top-timber-breadth line upon any particular timber, as 1, 2, 3, &c., which will give its proper dimensions thereon.

In the same manner the breadths of all the timbers may be laid from the projection to the horizontal plane, and, vice versa, from the elevation to the projection. Thus the height of each timber may also be transferred from the elevation to the projection, &c.

The principal utility of these draughts, therefore, is to exhibit the various curves of the ship's body, and of the pieces of which it is framed, in different points of view, which are either transverse or longitudinal, and will accordingly present them in very different directions. Thus the horizontal curves of the timbers, and the water-line, are represented on the floor-plane, all of which are transferred into the midship-frame, which is framed, in different points of view, which are either transverse or longitudinal, and will accordingly present them in very different directions. Thus the horizontal curves of the timbers, and the water-line, are represented on the floor-plane, all of which are transferred into the midship-frame, and the vertical curves of the timbers are all exhibited on the projection, although they appear as straight lines in the elevation and floor-plane.
The hull being thus fabricated, they proceed to separate the apartments by bulkheads, or partitions; to frame the ports; to fix the cut-heads and chess-tees; to form the hatchways and scuttles, and fit them with proper covers or gratings. They next fix the hold by the frames of the different hatchways; and build the manger on the lower deck, to carry off the water that runs in at the hawse-holes when the ship rides at anchor in a sea. The breast-room and magazines are then lined; and the gunnel, cabin, and gangways, fixed on the upper part of the ship. The ceats, keels, and rade ranges, by which the ropes are fastened, are afterwards bolted or nailed to the sides in different pieces.

The rudder, being fitted with its iron, is next hung to the stern-post; and the tiller, or bar, by which it is managed, let into a morrobine at its upper end. The stoppers, or leaden tubes, that carry the water off from the deck, are then placed in holes cut through the ship's sides; and the standards bolted to the beams and sides above the decks to which they belong. The poop-lanthorns are fast fixed upon the deck near the bow and stern; the forward and after frames, or cracles, placed under the bottom, to conduct the ship steadily into the water whilst launching.

Stowing and trimming of ships, the method of disposing of the cargo in a proper and judicious manner in the hold of a ship. A ship's sailing, steering, and wearing, and being lively and comparatively easy at sea in a storm, depend greatly on the cargo, ballast, or other materials, being properly disposed according to their shape and bulk, and the proportional dimensions of the built of the ship, which may be made too crab or too stiff to pass on the ocean with safety. These things render this branch of knowledge of such consequence, that rules for it ought to be endeavoured after, if not to prevent, as much as possible, the danger of a ship over-setting at sea, or being so laborious as to roll away her masts, &c. by being improperly stowed in the case.

When a ship is new, it is prudent to consult the builder, who may be supposed best acquainted with a ship of his own planning, and most likely to judge what her properties will be. The cargo of materials, according to the nature of them, ought to be disposed of to advantage, so as to put her in the best sailing trim; and at every favourable opportunity afterwards it will be proper to endeavour to find out her best trim by experiment.

Ships must differ in their form and proportional dimensions; and to make them answer their different purposes, they will require different management in the stowage which ought not to be left to mere chance, or done at random, as goods or materials happen to come to hand, which is too often the case that such improper stowage makes ships unfit for sea; therefore the stowage should be considered, planned, and contrived, according to the built and properties of the ship, which if they are not known should be inquired after. If she is narrow and high-built in proportion, so that she has a heavy list in the hold, it is a certain sign such a ship will require a great part of heavy goods, ballast, or materials, laid low in the hold, to make her stiff enough to bear sufficient soil without being in danger of over-reaching. But if a ship is built broad and low in proportion, so that she is stiff and will support herself without any weight in the hold, such a ship will require heavy goods, ballasting and hogging. If the ship is stowed too high up, to prevent her from being too stiff and laborious at sea, so as to endanger her masts being rolled away, and the hull worked loose and made leaky.

In order to help a ship's sailing, that she should be lively and easy in her pitching and ascending motions, it should be contrived by the stowage, that the principal and weightiest part of the cargo or materials should lie as near the main body of the ship, and as far from the extreme ends, fore and aft, as things will admit of. For it should be considered, that the roomy part of our ships lengthwise, forms a sweep or curve near four times as long as they are broad; therefore those roomy parts at and above the water's edge, which are made by a full haring and a broad transom to support the ship steady and keep her from plunging into the sea, and also by the entrance and run of the ship's having little or no accommodations for the purpose of water to support them, of course should not be stowed with heavy goods or materials, but all the necessary vacancies, broken stowage, or light goods, should be at these extremities ends fore and aft; and proportion as they are kept lighter by the stowage, the ship will be more lively to fall and rise easy in great seas; and this will contribute greatly to her working and sailing, and to prevent in the contrary way, that the principal weight may be more easily stowed in the main body of the ship, above the flattest and lowest floorings, where the pressure of the water acts the more to support it. See Navigation.

Stirres, mast, &c.

The mast of a ship is a long round piece of timber, elevated perpendicularly upon the keel of a ship, to which are attached the yards, the sail, and the rigging. A mast, with regard to its length, is either mainmast or mizzenmast, which is called a pole-mast, or composed of several pieces joined together, each of which retains the name of mast separately. The lowest of these is accordingly named the lower mast; the next in height is the top-mast, which is erected at the head of the former; and the highest is the top-gallant mast, which is prolonged from the upper end of the top-mast. Thus the two last are no other than a continuation of the first upwards.

The lower-mast is fixed in the ship; the foot, or heel of it, rests on a block of timber called the step, which is fixed upon the keel, and the top-mast is attached to the head of the cross-trees. The latter of these are two strong bars of timber, supported by two Primences, which are as shoulders on the other sides of the mast, a little under its upper end; these are fixed in the frame of the top of the support. Between the lower-mast-head, and the foremost of the cross-trees, a square space remains vacant, the sides of which are bounded by the two treestrees. Perpendicularly above this is the foremost hole in the cap, whose after-hole is solidly fixed on the head of the lower-mast. The top-mast is erected by the person whose effort is confined to the head of the lower-mast to the foot of the top-mast; and the upper end of the latter is accordingly guided into and conveyed up through the holes between the treestrees and the cap. Besides the parts already mentioned in the construction of masts, with respect to their length, the lower-masts of the largest ships are composed of several pieces united into one body. As these are generally the most substantial parts of various trees, a mast formed by this assemblage, is justly esteemed much stronger than one consisting of any single trunk, whose internal solidity may be very uncertain.

The whole is secured by several strong hoops of iron, driven on the outside of the mast, where they remain at proper distances.

Figs. 1, 2, and 3, Plate Masts, &c. represent one of Mr. George Smart's patent hulling masts. It is principally composed of four small beams ABDE, figs. 1 and 2, which are each quarters of one small tree; these are held at the proper distance apart by cross bars EF mortised into them. The spaces between the bars are filled up by thick planks GG, which have grooves cut across them to receive one-half of the bars FF as shown in fig. 3, and the whole is bound together by hoops HH. By this means a trunk is formed in every direction; for in every strain, before the mast can give way, the beams and planks on the side nearest the strain must compress, and those on the opposite side must be torn asunder lengthwise.

There are several other methods of constructing these masts, as right planks dovetailed together at the edges, or four planks tabbed into each other with oak wedges at the end of the tables, to prevent the end wood from cutting into each other.

Masts on these principles can be made at one half the expense of the common ones, and of the same strength without any increase of the weight.

Figs. 4 and 5, represent a contrivance included in Mr. Smart's patent for masts, by which temporary yards for ships can be made when at sea, and of such spars as can conveniently be carried on board a ship.

They are formed of two small spars, each half the length of the yard, which are sawn down lengthwise in two directions, so as to cut them into four branches, but left joined together at one end. A fig. 4 that end is then lopped so as to prevent splitting; the four pieces DEF, &c. are opened out as in the figure, and blocks of wood put in between them at GHIK to keep them apart; the two spars thus opened are joined together to make one yard at the block K formed of four pieces, of which is shown in fig. 5. It has a groove in it to receive the ends of one of the bars DEF in each spar and connect them; it has some small pieces put across in the angle of the groove, to hold the ends of the pieces DEF, so that when they are kept in their places, by a broad loop L, they cannot be drawn apart endways; the four pieces composing the block K are laid together, and put in between the bars, leaving a space between them to put in
wedges which are driven in until the pieces, fig. 5 are shoved out so as to fill the hoop and hold it firmly.

All masts may be made from one spar without joints; in that case the four pieces are left connected at each end, and the piece K is a plain block like the rest.

The principal articles to be considered in equipping a ship with masts are, 1st, the number; 2d, their situation in the vessel; and, 3d, their height above the water.

The masts being used to extend the sails by means of their yards, it is evident, that if their number was multiplied beyond what is necessary, the yards must be extremely short, that they may not entangle each other in working the ship, and by consequence the sail too narrow, and receive a small portion of wind. If, on the contrary, there is not a sufficient number of masts in the vessel, the yards will be too large and heavy, so as not to be managed without difficulty. There is a mean between these extremes, which experience and the general practice of the sea have determined; by which it appears, that in large ships every advantage of sailing is retained by three masts and a half yard.

The most advantageous position of the masts is undoubtedly that from whence there results an equilibrium between the resistance of the water on the body of the ship on one part, and of the direction of their effort on the other. By every other position this equilibrium is destroyed, and the greatest effort of the masts will operate to turn the ship horizontally about its direction; a circumstance which retards its velocity. It is counter-balanced indeed by the helm; but the same in-convenience still continues; for the force of the wind, having the resistance of the helm to overcome, is not entirely employed to push the ship forward. The aim of the resistance of the water should then be previously determined, to discover the place of the main-mast, in order to suspend the efforts of the water equally, and place the other masts so that their particular direction will coincide with that of the main-mast. The whole of this would be capable of a solution if the figure of the vessel was regular, because the point, about which the resistance of the water would be in equilibrium, might be discovered by calculation.

The exact height of the masts, in proportion to the form and size of the ship, remains yet a problem to be determined. The more the masts are elevated above the centre of gravity, the greater will be the surface of sail which they are enabled to present to the wind; so in an additional height seems to have been advantageous. But this advantage is diminished by the circular movement of the mast, which operates to make the vessel stoop to its effort; and this inclination is increased in proportion to the additional height of the mast, an inconvenience which it is necessary to avoid. Thus much is gained upon one hand is lost upon the other. To reconcile these difficulties, it is certain, that the height of the mast ought to be determined by the inclination of the vessel, and that the point of her greatest inclination should be the term of this height above the centre of gravity.

In order to secure the masts, and counterbalance the force of the current from the side of the sails impressed by the wind, and the agitation of the ship at sea, they are sustained by several strong ropes, extended from their upper ends to the outside of the vessel, called shrouds. These are further supported by other ropes, stretched from their heads towards the fore-part of the vessel.

The mast, which is placed at the middle of the ship's length, is called the main-mast; that which is placed in the forepart, the fore-mast; and that which is towards the stern, is termed the mizen-mast.

SHIESTS. See Scrinthus, and Rocks primitive.

SILVERS, or Sleeviers, in the sea-language, are the little rollers or round wheels of pulleys. See Pulley.

SHOE, a covering for the foot, usually made of leather, by the company of cordwainers.

SHOOK, horse. See Farriery.

SHOE, for an anchor, in a ship, the place for the anchor to rest, and fitted to receive the stock, &c. as to prevent the sheets, tacks, and other running-rigging, from galling, or entangling with the blocks.

SHOOTING, in the military art. See Artillery, Gunnery, and Projectiles.

SHOOTING, in sportsmanship, the killing of game by the gun, with or without the help of dogs.

The first thing which the sportsman ought to attend to is the choice of his fouling-piece. Convenience requires that the barrel should be as light as possible, at the same time it ought to possess that degree of strength which will make it not liable to burst. In a former article (Gun-smithery, vol. i. p. 890) it was stated that very little was gained by extending the length of the barrel. It ought, however, to bear some proportion to the bore, and be of sufficient length to hold the powder to infame. The usual length is now from 30 to 36 inches.

It may appear as an objection to this, that a duck-gun which is five or six feet long kills at a greater distance than a fouling-piece; but this is not owing to its length, but to its lighter and greater weight and thickness, which give it such additional strength, that the shot may be increased, and the charge of powder doubled, tripled, or even quadrupled. More, indeed, will depend on the goodness of the powder, and using a proper charge (which must be learned by trying the gun at a mark), than on the length of the barrel.

The point musl be made very generally used, and is reckoned superior to any other. The size of the shot must vary according to the particular species of game which is the object of the sportsman's pursuit, as well as adapted to the season. In the first month of partridge-shooting, No. 4 is most proper.

As hares also sit closer, and are thinly covered with fur, at this season, they may easily be killed with this shot at 30 or 35 paces. No. 5 is proper for shooting quails; and No. 6, for pheasants. About the beginning of October, when the partridges are stronger, and pleasant-shooting commences, No. 3 may be used.

In loading a piece, the powder ought to be slightly rammed down by only pressing the ramrod two or three times on the wadding, and not have the ramrod and then returning it into the barrel with a touch of the arm several times. The shot ought to be rammed down with some force, since it is from the shot being loose in the gun, and the spaces being left between it and the powder, that accidents most frequently happen by the bursting of guns. A sportsman ought never to carry his gun under arm with the muzzle inclined downwards, for this practice hinders the wadding and charge too much.

Immediately after the piece is fired it ought to be re-loaded; for, while the barrel is still warm, there is no danger of any moisture lodging in it to hinder the powder from falling down to the bottom. As it is found that the coldness of the barrel, and perhaps the moisture condensed in it, diminish the force of the powder in the first shot, it is proper to fire off a little powder before the piece is loaded with game; but this is not necessary when shooting, but this is not proper unless the touch-hole is very large. After every discharge the touch-hole ought to be pricked, or a small feather may be inserted to clear away any humidity or fœlth that has been contracted.

The sportsman having loaded his piece must next prepare to fire. For this purpose he ought to place his hand near the entrance of the ramrod, and at the same time grasp the barrel firmly. The muzzle should be a little elevated, for it is more usual to shoot low than high. This direction ought particularly to be attended to when the object is a little distant, because shot as well as ball only moves a certain distance point-blank, when it begins to describe the curve of the parabola.

Practice soon teaches the sportsman the proper distance at which he should shoot. The distance at which he ought infallibly to hit a piece of game with perfect shot, provided the aim is well taken, is from 22 to 32 paces for the footed, and from 40 to 45 paces for the winged game. Beyond this distance even to 30 or 35 paces, both partridges and hares are sometimes killed; but in general the hares are only slightly wounded, and carry away the shot; and the partridges at that distance present so small a surface, that they frequently escape untouched between the spaces of the circle. Yet it does not follow that a partridge may not be killed at 60 and even 70 paces distance; but these shots are rare.

In shooting at a bird flying, or a hare running across, it is necessary to take aim at the forepart of the object. If a partridge flies across at the distance of 30 or 35 paces, it will be sufficient to aim at the head, or at most but a small space before it. Another thing to be attended to is, that the shot be directed and then stopped by the motion of the arms at the moment of pulling the trigger; for, on the instant the hand stops in order to fire, however inconvenient the time may be, the bird gets beyond the line of aim, and the shot will miss it. A sportsman ought there-
before to accustom his hand while he is taking his follow the object. When a hare runs in a straight line from the greater that his influencing will he run the hazard either of missing, or at least not of killing dead, or, as it is sometimes called, clean.

A foolish piece should not be fired more than 20 or 25 times without being washed; a barrel when boil neither shoots so readily, nor carries the shot so far, as when clean. The flint, pan, and hammer, should be well wiped after each shot; this compounds greatly to make the piece go off quick, but then it should be done with so much precaution, that the barrel may be reddened whilst warm, for the reasons before advanced. The flint should be frequently changed, without waiting until it misses fire, before a new one is put in. Fifteen or eighteen shots, therefore, should only be fired with the same flint; the expense is too trilling to be regarded, and by changing it thus often much vexation will be prevented.

A gun also should never be fired with the prime of the preceding day; it may happen that an old priming will sometimes go off well, but it will more frequently contract moisture and smoke; fire from such a priming will most probably be missed, and that because the piece was not freshly primed.

For the information of the young sportsman we shall add a few more general remarks. In winter, when at a shot to seek for game in plains and open grounds; and in cold weather he may search little hills exposed to the sun, along hedges, among heaths, in stubbles, and in places where there is much furze and heath. The morning is the best time of the day, before the dew is exhaled, and before the game has been disturbed. The colour of the shotter's dress ought to be the same with that of the fields and trees; in summer it ought to be green, in winter a dark grey. He ought to hunt as much as possible against the wind, not only to prevent the game perceiving the approach of him and his dog, but also to enable the dog to scent the game distance.

He should never be discouraged from hunting and ranging the same ground over and over again, especially in places covered with heath, brambles, high grass, or young cabbage wood. The dog frequently suffer him to pass several times within a few yards of its form with out getting up. He should be still more patient when he has marked partridges into such places; for it often happens that after the hares have been sprung many times, they lie so dead that they will suffer him almost to treat upon them before they rise. Pleasants, quails, and woodcocks, do the same.

He ought to look carefully about him, never passing a bush, or tuft of grass, without examination; but he ought never to strike them with the muzzle of his gun, for it will loosen his wadding. He who patient beats and ranges his ground over again, without being discouraged, will always kill the greatest quantity of game; and if he is shooting in company, he will find game where others have passed without discovering any.

When he has killed, it is proper in his dog, that he may have the mortification to see game rise which he cannot shoot. When he has killed a bird, instead of being anxious about picking it up, he ought to follow the rest of the covey with his eye till he

Three species of dogs are capable of receiving the proper instructions and of being trained. These are the smooth pointer, the rough pointer, and the spaniel. The smooth pointer is the best dog in his range, but in general is proper only for an open country.

The greatest part of these dogs are afraid of water, branches, and thickets; but the smooth pointer and the rough pointer are easily taught to take the water, even in cold weather, and to range the woods and rough places as well as the plain. Greater dependence may therefore be had on these two last species of dog than on the smooth pointer.

The education of a pointer may commence when he is only five or six months old. The only lessons which he can be taught at this time are, to fetch and carry any thing when desired; to come in when he runs far off, and to go behind when he returns; using, in the one case, the words here, come in, and in the other, back, or behind. It is also necessary at this period to accustom him to the sound of time to place of time in any country; for he is not at first to be tied too long. He should be let loose in the morning, and fastened again in the evening. When a dog is not early accustomed to be chained, he disturbs every one in the neighborhood by barking and howling. It is also of importance that the person who is to train him should give him his food.

When the dog has attained the age of ten or twelve weeks, he should be taken into the field to be regularly trained. At first he may be allowed to follow his own inclination, and to run after every animal he sees. His instinctive cagering ness will soon abate, and he will pursue only partridges and hares. He will soon become tired of following partridges in vain, and will content himself after having flushed them, to follow them with his eyes. It will be more difficult to prevent him from following hares than partridges.

All young dogs are apt to take; that is, to hunt with their noses close to the ground, to follow birds rather by the track than by the wind. But partridges he much better to dogs if he approaches it in the manner of the birds. The dog that winds the scent approaches the birds by degrees, and without disturbing them; but they are immediately alarmed, when they see a dog tracing their footsteps. When you perceive that your dog is committing this fault, call him to him in an angry tone, hold up; he will then grow uneasy and agitated, going first to the one side and then to the other, until the wind gives him the scent of the birds. After finding the game four or five times in this way, he will take the wind of himself, and hunt with his nose high. If it is difficult to correct this fault, it will be necessary to put the puddle-peg upon him. This is of very simple construction, consisting only of a piece of oak or deal inch-board, one foot in length, and an inch and a half in breadth, tapering a little to one end; at the broader end are two holes, running longitudinally, through which the tail of the dog is put, and the whole is buckled round his neck; the piece of wood being projected beyond his nose, is then fastened with a piece of leather thong to his under jaw. By this means the peg advancing seven or eight inches beyond his snout, the dog is prevented from putting his nose to the ground and raising.

As soon as the young dog knows his game, you must bring him under complete subjection. If he is tractable, this will be easy; but if he is still a little wild, or has been taught to the trash cord, which is a rope or cord of 20 or 25 fathoms in length fastened to his collar. If he refuses to come back when called, you must check him smartly with the cord, which will often bring him upon his haunches. But be sure you never call him except when you are within reach of the cord. After repeating this several times, he will not fail to come back when called; he ought then to be dressed, and a bit of bread should be given him. He ought now constantly to be tied up; and never unchained, except when you give him his food, and even then only when he has done something to deserve it.

The next step will be to throw down a piece of bread on the ground, at the same time taking hold of the dog by the collar, calling him, "take heed, softly." After having held him in this manner for some time, he will be taught to lie down, and to not get up until you give him the order to rise. If he is impatient to lay hold of the piece of bread before the signal is given, correct him gently with a small whip. Repeat this lesson until he "takes heed" well, and no longer requires to be held fast to prevent him from laying hold of the bread. When he is well accustomed to this manage, turn the bread with a stick, holding it in the manner you do a feeding-piece, and having done so, cry "take heed!" He never forgets this lesson; he will not eat either in the house or field, without having first made him take heed in this manner.

Then, in order to apply this lesson to the game, try small pieces of bread in dog's head, with the dung of partridge; take these in a linen bag into the fields, stubbles, ploughed grounds, and pastures, and there put the pieces in several different places, marking the spots with little cleft pickets of wood, which will be readily visible in finding the dog, putting pieces of card in the tracks. This being done, cast off the dog and conduct him to these places, always hunting in the wind. After he has caught the scent of the bread, he will be very eager to take it up, and seems eager to fall upon it, cry to him in a menacing tone, "take heed," and if he does not stop immediately, correct him with the whip. He will soon comprehend what is required of him, and will stand.

At the next lesson, take your gun charged only with powder, walk gently round the piece of bread once or twice, and fire instead of crying seize. The next time of practicing this lesson, walk round the bread four or five times, but in a greater circle than before, and continue to do this until the dog is conquered of his impatience, and will stand without moving until the signal is given him.

When he keeps his point well, and stands steady in this lesson, you may carry him to the birds; if he runs in upon them, or barks when they spring up, you must correct him; and if he continues to do so, you must return to the fried bread; but this is seldom necessary.

When the dog has learned by this use of the bread to take heed, he may be carried to the fields with the trash-cord dragging on the
ground. When he springs birds for the first time, if he runs after them or backs, check him by calling out to him, "Take heed!" If he points properly, care him, but you ought never to hunt without the cord until he points straight.

The principal objects of this sport are, 1. Partridges, which pair in the spring, and lay their eggs (generally from 15 to 20) during May and part of June. The young begin to fly about the end of June, and their plumage is complete at the beginning of October. The mare has a conspicuous horse-shoe upon her breast, and an obtuse spur on the hinder part of the leg, which distinguishes him from the female. He is also rather larger.

When a sportsman is shooting in a country where the birds are thin, and he no longer chooses to range the field for the bare chance of meeting with them, the following method will show him where to find them on another day. In the evening, from sun-set to nightfall, he should post himself in a field, at the foot of a hedge or at the edge of a wood, and there wait until the partridges begin to call or juck, which they always do at that time; not only for the purpose of drawing together when separated, but also when the birds composing the company are dispersed. After calling in this manner for some little space of time, the partridges will take to flight; then, if he marks the place where they alight, he may be assured they will be there the whole night, unless disturbed.

2. The pleasant lays its eggs generally in the woods, the number of which is ten or twelve. Partridges are accounted stupid birds; for when they are surprised they will frequently squat down like a rabbit, supposing themselves to be in safety as soon as their heads are concealed; and in this way they will sometimes suffer themselves to be killed with a stick. They love low and moist places, and haunt the edges of those pools which are found in woods, as well as the high grass of marshes that are near at hand; and above all, places where there are clumps of alders.

3. Grouse, or moor-game, are found in Wales, in the northern counties of England, and in the northern and central parts of Scotland. They chiefly inhabit those mountains and moors which are covered with heath, and seldom descend to the low grounds. They fly in companies of four or five brace, and love to frequent moisy places, particularly in the middle of the day, or when the weather is warm. In pursuing this game, when the pointer sets, and the sportsman perceives the birds running with their heads erect, he must run after them as fast as he can, in the hope that he may get near enough to shoot when they rise upon the wing; for he may be pretty certain they will not lie well that day. As these birds are apt to grow soon putrid, they ought to be drawn carefully the instant they are shot, and stuffed with heath; and if the feathers happen to be wetted, they must be wiped dry.

4. The woodcock is a bird of passage; it commonly appears about the end of October, and remains until the middle of March. Woodcocks are fattest in December and January, but from the end of February they are lean. At their arrival they drop any where, but afterwards take up their residence in copes of nine or ten years growth. They seldom, however, stay in one place longer than twelve days. During the day they remain in those parts of the woods, where there are void spaces or glades, picking up earthworms and grubs from the fallen leaves. In the evening they go to drink and to roost in marshes and springs, after which they repair to the open fields and meadows for the night.

5. The snipe is a bird of passage as well as the woodcock. In the month of November they grow fat. Snipes frequent springs, bogs, and marshes, fly heavily against the wind. The slant and cross-shots are rather difficult, as the birds are small and fly very quickly. The sportsman ought to look for them in the direction of the wind; because if they fly towards him, he will present a fairer mark.

6. The wild duck also may in some measure be accounted a bird of passage, and arrives here in great flocks from the northern countries in the beginning of winter. Still, however, a good many remain in our marshes and fens during the whole year, and breed.

The wild duck differs little in plumage from the tame duck, but is more distinctly distinguished by its size, which is less; by the neck, which is more slender; by the foot, which is smaller; by its bill, which are more black; and above all, by the web of the foot, which is much finer and softer to the touch.

In the summer season, when it is known that a team of young ducks are in a particular piece of water, and just beginning to fly, the sportsman finds them early in the morning dabbling, at the edges of the pool, and amongst the long grass, and then he may very near to them; it is usual also to find them in those places at noon.

In the beginning of autumn almost every pool is frequented by teams of wild ducks, which remain there during the day, concealed in the rushes. If these pools are of small extent, two shooters, by going one on each side, making a noise and throwing stones into the rushes or rushes from them fly up; and then they will in this way frequently get shots, especially if the pool is not broad, and contracts at one end. But the surest and most successful way, is to launch a small boat or row on the pool, and to plant the rushes by the edge of the boat, and behind the rushes which are found; at the same time making as little noise as possible. In this manner the ducks will suffer the sportsmen to come sufficiently near them to shoot, and for it often happens that the ducks, after having flown up, only make a circuit, return in a little time, and again alight upon the pool. Then the sportsmen endeavour a second time to come near them. If several shooters are in company, they should divide; two should go in the boat, whilst the other spread themselves about the edge of the pool, in order to shoot the ducks in their flight. In pools which will not admit a row, water-sparrows are absolutely necessary for this sport.

In winter they may be found on the margins of little pools; and when pools and rivers are frozen up, they must be watched for in places where the springs and waters which do not freeze. The sport is then much more certain, because the ducks are confined to these places in order to procure aquatic herbs, which are almost their only food at this period.

SHORLITE. No word has been used by mineralogists with less limitation than shorl. It was first introduced into mineralogy by Constvedt, to denote any stone of a columnar form, considerable hardness, and a specific gravity from 3 to 3.4. This description applied to a very great variety of substances; and succeeding mineralogists, though they made the word more definite in its signification, let it still so general, that under the designations of shorl almost twenty distinct species or minerals were included. Mr. W. Emmet first defined the word shorl precisely, and restricted it to one species of stones. It occurs commonly in granite, gneiss, and other similar rocks; often in mass, but very frequently crystallized. The primitive form of its crystals is an obtuse rhomboid, the solid angle at the summit of which is 139°, having rhomboidal faces, with angles of 114° 12' and 65° 45': but a usually occurs in 3, 5, 8, 9, or 12 sided prisms, terminated by a post of five-sided prisms, variously truncated. Colour black. Found in mass, disseminated and crystallized. Crystals three-sided prisms, having their lateral edges truncated. Sometimes terminating in a pyramid. Lateral prisms terminated by trin- gulated. Vitreous. Fracture conchoidal. Opaline. Scratch grey. Feel cold. Specific gravity from 3 to 3. It becomes electric by friction. When heated to redness, its colour becomes brownish red; and at 1277 Wedgewood, it is converted into a brownish compact enamel. According to Wiegler, it is composed of

\[ 41.25 \text{ alumina} \]
\[ 33.18 \text{ silica} \]
\[ 20.00 \text{ iron} \]
\[ 5.41 \text{ manganese} \]

100.02

SHORLITE ELECTRIC. This stone was first made known in Europe by specimens brought from Ceylon; but it is now found frequently forming a part of the composition of mountains, and sometimes in amorphous pieces, but much more frequently crystallized in three or nine-sided prisms, with four-sided summits.

Colour usually green; sometimes brown, red, blue. Found in mass, in grains, and crystallized. Crystals three, six, or nine-sided prisms, variously truncated. Faces usually striated longitudinally. Its texture is foliated. Specific gravity 3. Colour brown, sometimes with a tint of green, blue, red, or yellow. When heated to 200° Fahrenheit, it becomes electric, one of the sums negatively and the other positively. It reddens when heated, and is fusible per se, with white intumesce, into a white or grey enamel. According to Vaupelium, it is composed of

\[ 40 \text{ silica} \]
\[ 39 \text{ alumina} \]
\[ 12 \text{ oxide of iron} \]
\[ 4 \text{ lime} \]
\[ 2.3 \text{ oxide of manganese} \]

97.5

SHORLITE. A stone which received its name from Mr. Klaproth, is generally found in oblong masses, which, when regular, are six-sided prisms, inserted in granite. Its
Shot, case, formerly consisted of all kinds of old iron, nails, musket-balls, stones, &c., used as above, which, by their friction against one another, and against the sides of the cylinder, they are rendered perfectly round and very smooth. The other patent-shot is cast in moulds, in the same way as bullets are.

Shot, common small, or that used for fencing, should be well sized; for, should it be too great, then it flies thin and scatters too much; or if too small, then it has no weight and strength to penetrate far, and the bird is apt to fly away with it. In order, therefore, to have it suitable to the occasion, it not being always to be had in every place fit for the purpose, we shall set down the true method of making all sorts and sizes under the name of the shot, formerly made after the following process:

Take any quantity of lead you think fit, and melt it down in an iron vessel; and as it melts keep it stirring with an iron ladle, skimming off all impurities whatever that may arise at top; when it begins to look of a greenish colour, stern on it as much arispermatic or yellow orpiment, finely powdered, as will lie on a sliding, to every twelve or fourteen pounds of lead; then stirring them together, the orpiment will flame. The ladle should have a notch on one side of the brim, for more easily pouring out the lead; the ladle must remain in the melted lead, that its heat may be the same with that of the lead, to prevent inconveniences which otherwise might happen by its being either too hot or too cold; then, to try your lead, drop a little of it into water, and if the drops prove round, then the lead is of a proper heat; if otherwise, and the shot have tais, then add more orpiment to increase the heat, till it is found sufficient.

Then take a plate of copper, about the size of a trencher, which must be made with a hollowness in the middle, about three inches compass, within which must be bored about 40 holes according to the size of the shot which you intend to cast; the hollow bottom should be laid on the shot, and then, by leading the lead molten upon it, then take some lead and pour molty on the coals on the plate, and it will make its way through the holes into the water, and form itself into shot; do thus till all your lead is run through the holes of the plate, taking care, by keeping up the coals, that the lead does not cool, and so stop up the holes.

While you are casting in this manner, another person with another ladle may catch some of the shot, placing the ladle four or five inches underneath the plate in the water, by lead, and when they are disposed, fetch them with a bottle, and thus you will have your shot to your command.

And to render the coolness of your lead and plate, you must blow your fire; observing, that the cooler your lead is, the larger will be your shot; as, the hotter it is, the smaller it will be.

After you have done casting, take them out of the water, and dry them over the fire with a gentle heat, stirring them continually that they do not melt; when dry, you are to separate the great shot from the small, by the help of a vase made for that purpose, according to their several sizes. But those who would have very large shot, make the lead trickle with a stick out of the ladle into the water, without the plate. If it stops on the plate, and yet the plate is not too cool, give but the plate a little knock, and it will run again; care must be had that none of your implements are greasy, oily, or the like; and when the shot, being separated, are found too large, or too small, for your purpose, or otherwise imperfect, they will serve again at the next operation.

Shot, tin-case, in artillery, is formed by putting a great quantity of small iron shot into a tin cylindrical box called a canister, that just fits the bore of the gun. Leaden bullets are sometimes used in the same manner; and it must be observed, that whatever number or sizes of the shots are used, they must weigh with their cases nearly as much as the shot of pieces.

SHREW-MOUSE. See Sorex.

SHRIMP. See Cancer.

SHRINE, in ecclesiastical history, a case or box, to hold the relics of some saint.

SHROUDS. See Shrowds.

SHROWDS. In a ship, are the great ropes which come down both sides of the mast, and are fastened below to the chains on the ship's side, and aloft to the top of the mast; being parcelled and served, in order to prevent the mast's galling them.

The topmast shrouds are fastened to the topmasts, by dead-eyes and Iamards, as the others are. Some of the terms relating to the shrowds are: rake, shrowds, which is, sheathed them; and, set up the shrowds; that is, set them in position.

SHUTTLE, in the manufactures, an instrument much used by weavers, in the middle of which is an eye, or cavity, wherein is enclosed the end of the wool. See Weaver.

Shi, in music a seventh note or sound, added by Le Maire to the six antient notes invented by Guido Artusino, viz. ut, re, mi, fa, sol, la.

SIBBALDIA, a genus of plants belonging to the class of pentandria, and, to the order of angiopterous; and in the natural method ranking under the 35th order, sentiss. The calyx is divided into ten segments. The petals are five, and are inserted into the calyx. The styles are attached to the side of the germen. The seeds are five. There are three species belonging to this genus, the procumbens, erecta, and alata. The procumbens, or reclining sibbaldia, is a native of North Britain.

SIBTHORPIA, a genus of plants belonging to the class of chlamydia, and to the order of angiopterous; and in the natural system classed with the group of which is doubtful. The calyx is spreading, and divided into five parts, almost to the base. The corolla is divided into five parts in the same manner, which are rounded, equal, spreading; and of the length of the calyx. The stamina grow in pairs at a distance from each other. The capsule is compressed, orbicular, bilocular, the partition being transverse. There is one species; the Europs, or bastard wood-sorrel, Another of South Britain. It blossoms from July to September, and is found in Cornwall on the banks of rivulets.

SICE-ACE, a game with dice and tables, whereas five may play; each having six men, and the last out losing. At this game, they load one another with aces; sixes bear away; and doubles, drinks, and throws again.

SICYOS, a genus of plants belonging to the class of monocotyledons, to the order of syngeenia; and in the natural system arranged under the 34th order, cumbibacter. The male flowers have their calyx quinquidented, their corolla quinquepartite, and there are three filaments, while the stamens have their calyx and corolla similar; but their style is trid, and their stipe monoporous. There are three species, the angulata, bicinata, and garcini, which are all forest plants.

SIDA, yellow or Indian mallow: a genus of plants belonging to the class of monadelphus, and to the order of polyandria; and in the natural system ranked under the 37th order, commelinae. All are fugitans. The calyx is simple and angulated; the style is divided into many parts; there are several capsules, each containing one seed. There are 99 species, all natives of warm climates; and most of them are found in the East or West Indies. The Chinese make cords of the sida ablation. This plant loves water, and may be advantageously planted in marshes and ditches, where nothing else will grow. The maturation of the smaller species is finished in fifteen days; of the larger in a month. The strength and goodness of the thread appears to be in proportion to the perfection of the vegetation, and to the distance the plant is kept at from other plants. The fibres the
in strata, of which there are sometimes six; they are not quite straight, but preserve an undulating direction, so as to form a network in their natural positions. Their smell resembles that of hemp; the fibres are winter, but more dry and harsh, than those of hemp. The harshness is owing to a greenish gluten which connects the fibres; and the white colour must always be obtained at the expense of having this kind of thread less supple; when of its natural hue, it is very soft and flexible.

SIDERIA, in natural history, the name of a genus of crystals, used to express those altered in their figure by particles of iron. These are of a rhomboidal figure, and composed only of six planes. Of this genus there are four known species: 1. A colorless, pellucid, and thin one; found in considerable quantities among the iron ores of the forest of Dean in Gloucestershire, and in several other places. 2. A dull, thick, and brown one, not uncommon in the same places with the former. And, 3. A black and very glossy one, a fossil of great beauty; found in the same place with the others, as also in Leicestershire and Sussex.

SIDERITE, a substance discovered by Mr. Meyer, and by him supposed to be a new minerals. Bergman and Kirwan discovered that it is nothing else than a natural combination of the phosphoric acid with iron. Mr. Klaproth of Berlin also came to the same conclusion, without any communication with Mr. Meyer. It is extremely difficult to separate this acid from the metal; however, he found the artificial compound of phosphoric acid and iron to agree in its properties with the calc siderite, obtained by Bergman and Meyer from the cold short iron extracted from the swampy or marshy ores.

SIDERITIS, IRONWORT; a genus of plants belonging to the class of thallophyta, and to the order of gymnospermae; and in the natural system ranging under the 49th order, verticillata. The stamens are within the tube of the corolla. There are two stigmas, one of which is cylindrical and concave; the other, which is lower, is membranous, and is attached to the other. The species are 19.

SIDEROXYLM, IRONWOOD; a genus of plants belonging to the class of pentadria, and to the order of monogynia; and in the natural system ranging under the 49th order, durinumose. The corolla is cut into five parts, the calix or segments being incurvated alternately; the stigma is simple; the berry contains five seeds. There are nine species: 1. The seed of smooth iron-wood; 3. melanophyllum, lauric-leaved iron-wood; 4. gymnocarpum, 5. sericicum, silky iron-wood, native of New South Wales; 6. tomentum; 7. tenax, silvery-leaved iron-wood, a native of Carolina; 8. lycodes, willow-leaved iron-wood, a native of North America; 9. decandrum. The wood of these trees are very close and solid, has given occasion for this name to be applied to them, it being a necessary to sink in water. As they are natives of warm countries, they cannot be preserved in this country unless tie are placed in the winter in a warm stove, the others in a green-house. They are propagated by seeds, when these can be procured from abroad.

SIEGE, in the art of war, the employment of an army before a fortified place, with a design to take it.

SIENITE. See Rocks, primitive.

SIGESBECKIA, a genus of plants belonging to the class of thallophyta, and to the order of polygama superflua, and in the natural system ranging under the 49th order, compositae. The receptacle is paleaceous; the pappus wanting; the external calyx is papillosus, proper, and spreading; the radius is halved. There are three species: 1. The orientalis, which is a native of India and China. 2. The occidentalis, which is a native of Virginia. 3. The flosculosa, a native of Pers. SIGS OF A quadrant, &c. thin pieces of brass, raised perpendicularly on its side, or on the index of a theodolite, circumferentor, &c. They have each an aperture, or slit, up the middle, through which the visual rays pass to the eye, and distant objects are seen.

SIGNS, in astronomy, a constellation containing a twelfth part of the zodiac, or 30'. See Zodi.

The names of the signs, in the order wherein they follow each other, are: aries, taurus, gemini, cancer, leo, virgo, libra, scorpio, sagittarius, capricornus, aquarius, pisces. The three first of these signs are called the vernal, or spring-signs; the next three, cancer, leo, virgo, the autumnal, or summer signs; libra, scorpio, and sagittarius, the astronomical signs; and capricornus, aquarius, pisces, the winter signs. The vernal, or spring, and autumnal and astral signs are also called the northern, and the autumnal and brumal the southern signs.

SIGN-MANUAL, in law, is used to signify a bail, or writing, signed by the king's own hand-writing.

SIGNALS, certain alarms or notices used to communicate intelligence to a distant observer. Signals are made by firing artillery, and displaying colours, lanterns, or fireworks; and these are combined by multiplication and repetition. Thus, like the words of a language, they become arbitrary expressions, to which we have previously annexed particular names; and hence we may say that the general sources of intelligence throughout a naval armament, &c.

Signals ought to be distinct, with simplicity. They are simple when every instruction is expressed by a particular token, in order to avoid any mistakes arising from the double purport of one signal. They are distinct when issued without precipitation, when sufficient time is allowed to observe and obey them, and when they are exposed in a conspicuous place, so as to be readily perceived at a distance.

All signals may be reduced into three different kinds, viz. those which are made by the sound of particular instruments, as the trumpet, horn, or life; to which may be added, striking the bell, or beating the drum. Those which are made by displaying pendant, ensigns, and flags of different colours: or by sounding cannon-shots from the ship, and by this means to call the attention of those on shore. Those which are made by rockets of different kinds; by firing cannon on small arms; or by artificial fire-works; and by lanterns.

For the best guns will serve equally in the day or night, or in a fog, to make or communicate signals, or to raise the attention of the hearers to a future order. This method, however, is attended with some inconveniences, and should not be used indiscriminately. Too great a report of the cannon is apt to mix the sounds, and to cause confusion, as well as to discover the track of the squadron. The report and flight of rockets is liable to the same objection, when at a short distance from the enemy.

It is then by the combination of signals, previously known, that the admiral conveys orders to his fleet; every squadron, every division, and every ship of which, has its particular signal. The instruction may therefore occasionally be given to the whole fleet, or to any of its squadrons; to any division of those squadrons, or to any ship of those divisions.

Hence the signal of command may at the same time be displayed for three divisions, and for three ships of each division; or for three ships in each squadron, and for only nine ships in the whole fleet. For, the general signal of the fleet being shown, if a particular pendant is also thrown out from some particular place of mast with the general signal, it will communicate intelligence to nine ships that wear the same pendant.

The preparatory signal given by the admiral to the whole or any part of his fleet, is immediately answered by those to whom it is directed; by showing the same signal, to testify that they are ready to put his orders in execution. Having obtained their answer, he will show the signal which is to direct their operations: as, to chase, to form the line, to begin the engagement, to board, to double upon the enemy, to rally or return to action, to continue the fight, to retreat and save themselves. The dexterity of working the ships in a fleet depends upon the precise moment of executing these orders, and on the general harmony of their movements; a circumstance which evinces the utility of a signal of preparation.

As the extent of the line of battle, and the fire and smoke of the action, or other circumstances in navigation, will frequently prevent the officers from being seen through the smoke of the fleet, therefore three signals, repeated by the officers next in command, by ships appointed to repeat signals; and, finally, by the ship or ships for which they are intended. The ships that repeat the signals, besides the chief of squadrons or divisions, are usually frigates lying to windward or to leeward of the line. They should be extremely vigilant to observe and repeat the signals, whether they are to transmit the order of the command in any case to the vessels, to any part of the fleet; or to report the fortune or distressful situation of any part thereof. By this means all the ships from the van to the rear will, unless disabled, be ready at a moment's warning to put the admiral's designs in execution.

To preserve order in the repetition of signals, and to favour their communication, every ship in the squadron is embrazed, from the commander in chief to the ships in his rear; they are calculated, the commanders of the squadrons repeat after the admiral; the chiefs of the divisions, according to their order of the line, after the commanders of the squadrons; and the particular ships after the chiefs of the divisions.
and those in return, after the particular ships, vice versa, when the object is to convey any intelligence from the latter to the admiral. Besides the signals above-mentioned, there are others for different ranks of officers; as

**Signs.**

**Signature.** In printing, is a letter put at the bottom of the first page at least, in each sheet, as direction to the binder, in folding, gathering, and collating them. The signatures consist of the capital letters of the alphabet, which change in every sheet: if there are more sheets than letters in the alphabet, to the capital letter is added a small one of the same sort, as Aa, Bb; which are repeated as often as necessary. In large volumes it is usual to distinguish the number of alphabets, after the first three or four, by placing a figure before the signature, as 5th, 6th, &c.

**Signet.** One of the king's seals, made use of in sealing his private letters, and all grants that pass by him signed under his majesty's hand: it is always in the custody of the secretaries of state.

**Significative.** In law, a writ which issues out of the court of chancery, on a certificate given by the ordinary of a person's standing excommunicated forty days, in order to have him imprisoned till he submits to the authority of the court.

**Silene, Catchfly, or viscous campion.** A genus of plants belonging to the class of decandria, and order of tricygium; and in the natural system arranged under the 23rd order, carpyrophyllae. The calyx is ventricose; the petals are fire in number, bifid and undulated, and crowned by a nectarium; the capsule is cylindrical, covered, and tri-locular. There are 66 species, of which seven are natives of Britain and Ireland.

**Silica.** There is a very hard white stone, known by the name of quartz, very common in almost every part of the world. Sometimes it is transparent and crystallized, and then is called rock crystal. Very frequently it is in the form of sand. As this stone, and several others which resemble it, as flint, agate, calcedony, &c. have the property of melting into a glass when heated along with fixed alkali, they were clasped together by mineralogists under the name of vitrifiable substances. Mr. Pot, who first described their properties in 1746, gave them the name of silicious stones, on the supposition that they were all chiefly composed of a peculiar earth called silicious earth or silica. This earth was known to Glauber, who describes the method of obtaining it: but it was long before its properties were accurately ascertained. Geoffroy endeavored to prove that it might be converted into lime, and in this respect it might be converted into alumina; but these assertions were refuted by Carthus, Scheele, and Bergman. To this last chemist we are indebted for the first accurate detail of the properties of silica.

1. Silica may be obtained pure by the following process: Mix together, in a crucible, one part of pounded flint or quartz, and three parts of potass, and apply a heat sufficient to melt the mixture completely. Dissolve the mass formed in water, saturate the potass with muriatic acid, and evaporate to dryness. Towards the end of the evaporation the liquid assumes the form of a jelly; and when all the moisture is evaporated, a white mass remains behind. This mass is to be washed in a large quantity of water, and dried; it is then silica in a state of purity.

2. Silica, thus obtained, is a fine white powder, without either taste or smell. Its particles have a hard feel, as if they consisted of very minute grains of sand. Its specific gravity is 2.66. It may be subjected to a very violent heat without undergoing any change. Lavrovier and Morveau exposed it to the action of a fire maintained by oxygen gas without any alteration. Sousisse, indeed, has succeeded in fusing, by means of the blowpipe, a portion of it so extremely minute as scarcely to be perceptible without a glass. According to the calculation of this philosopher, the temperature necessary for producing this effect is equal to 4034° Wedgewood.

3. It is insoluble in water except when newly precipitated, and then one part of it is soluble in 1000 parts of water. It has no effect on vegetable colours.

4. It is capable of absorbing about one-fourth of its weight of water, without letting any drop fall from it; but on exposure to the air, the water evaporates very readily. When precipitated from potass by means of muriatic acid and slow evaporation, it retains a considerable portion of water, and forms with it a transparent jelly; but the moisture gradually evaporates on exposure to the air.

Silica may be formed into a paste with a small quantity of water; this paste has not the smallest ductility, and when dried forms a loose, friable, and incoherent mass.

Silica is capable of assuming a crystalline form. Crystals of it are found in many parts of the world. They are known by the name of rock crystal. When pure they are transparent and colourless; when glass: they assume various forms; the most usual is a hexagonal prism, surmounted by hexagonal pyramids on one or both ends, the angles of the prism corresponding with those of the pyramids. Their hardness, equal to 7.

11. Their specific gravity is 2.66.

4. Silica neither combines with oxygen, with the simple combustibles, nor with metals; but it combines with many of the metallic oxides by fusion, and forms various coloured glasses and enamels.

5. Azote has no action on silica, neither has muriatic acid when the silica is in a solid state; but when the silica is combined with an excess of alkali, muriatic acid dissolves the compound, and forms a permanent solution.

By concentrating this solution, the silica separates from it in the form of a jelly.

6. There is a strong affinity between silica and fixed alkalies. It may be combined with them either by fusing them along with it in a crucible, or by boiling the liquid alkalies over it. When the silica exceeds the compound is transparent and colourless like rock crystal, and is neither acted on by water, nor (excepting one) by acids. This is the substance so well known under the name of glass. See Glass.

Silica is not acted on by ammonium, whether in the gaseous or liquid state.

7. There is a strong affinity between barytes and silica. When barytes is poured into a solution of silica in potass, a precipitate appears, which is considered by Morveau as the two earths in a state of combination. Barytes and silica may be combined by means of heat. The compound is of a greenish colour, and coheres but imperfectly. The effect of heat on various mixtures of barytes and silica will appear from the following experiments of Mr. Kirwan:

**Proportions.**
- 80 Silica
- 20 Barytes
- 75 Silica
- 20 Barytes
- 60 Silica
- 33 Barytes

**Heat.**
- 135° Wedg.
- 150
- 150

**Effect.**
- A white brittle mass.
- A brittle hard mass, semitransparent at the edges.
- Melted into a hard somewhat porous porcelain mass.
The silkworm is a native of China, and feeds on the leaves of the white mulberry. That inhuman nation was acquainted with the manufacture of silk from the most remote ages; but it was scarcely known in Europe before the time of Augustus. Its beauty attracted the attention of the luxurious Romans; and after the calamitous reign of Flamininus, it became a common article of dress. It was brought from China at an enormous expense, manufactured again by the Phenicians, and sold at Rome for its weight of gold. In the reign of Justinian this commerce was interrupted by the conquests of the Scythian tribes, and all attempts to procure it failed till two Persian monks had the address to convey some of the eggs of the insect from China to Constantinople, concealed in the hollow of a canoe. They were hatched, and the breed carefully propagated. This happened in 553; and some years after we find that the Greeks understood the art of procuring and manufacturing silk as well as the Romans, who, with their emperor, Loger, king of Sicily, brought the manufacture to Constantinople in 1130, forcibly carrying off the weavers from Greece, and settling them in Sicily. From that island the art passed into Italy, and thence into France: and the revocation of the edict of Nanius established the manufacture of silk in Britain.

Silk, as spun by the animal, is in the state of fine threads, varying in colour from white to reddish yellow. It is very elastic, and has considerable properties, if we consider its small diameter. It is covered with a varnish, to which its elasticity is owing. This varnish is soluble in boiling water; but alcohol does not act upon it. Hence it has been compared to a gum, though it approaches much nearer to a gelatine; since Berthollet has shown that it is precipitated by tin and by muriatic acid. It differs, however, from gelatine in several particulars. Alain throws it into a solution of a dirty white, and that of copper of a dark brown, and spathul of iron of a brown colour. When the water is evaporated, the varnish is obtained of a black colour, brittle, and of a shining fracture. Its weight is nearly one-third of the raw silk from which it was extracted. It may be separated from silk by soap as well as water, and the soap in remaining has taken it soon putrefy.

Besides the varnish, silk contains another substance to which it owes its yellow colour. This substance possesses the properties of resin. It is yellow, soluble in alcohol, and in a mixture of alcohol and muriatic acid. Beuville has ascertained, that by this last mixture it may be separated completely, and the silk deprived of it assumes a fine white colour.

The chemical properties of silk itself have been but imperfectly examined. It is not acted upon by water or alcohol, has no taste, and is but imperfectly combustible: though it burns rapidly blackens and decomposes it. When distilled, it yields, according to Neumann, an uncommonly great proportion of ammonia.

The alkalies dissolve it by the assistance of heat: and it is not unlikely that they form with it an animal soap.

It is dissolved likewise by sulphuric and muriatic acids, and by nitric acid. By the
action of this last acid, Berthollet obtained from silk some oxalic acid, and a fatty matter which swam on the surface of the solution. By a similar treatment, Welter obtained fine yellow crystals, very combustible, to which he gave the name of cotton, but which, at the same time, that silk is kept in a damp place it rots (to use the common language) in a much shorter time.

Silk, manufacture, or preparation of. When the silkworms have completed their cocoons or silkworms (thl., in the 359), they are collected, and put into little baskets; and thus exposed to the heat of an oven, to kill the insect, which, without this precaution, would not fail to open itself to go away and leave these new broods abroad, it has acquired within.

Ordinarily, they only wind the more perfect balls; those that are double, or too weak, or too coarse, are laid aside, not as altogether useless, but that, being improper for winding, they are reserved to be drawn out into skeins. The balls are of different colours: the most common are yellow, orange-colour, isabella, and flesh-colour; there are some also of a sea-green, others of a sulphur-colour, and others white; but there is no necessity for separating the colours and shades to wind them apart, as all the colours are to be lost in the future scouring and preparing of the silk.

The goodness of silk is best distinguished by its lightness. The organzine silk is the best of any made in the country of Piedmont, and its two threads are equal in fineness, the thl., in the shortness, smoothness, and fineness, length, for the thread of the first twist. For the second, it matters not whether the single thread is strong between the two are joined, unless to see whether the first twist proves well. It is necessary that he be clean, and it is to be observed, that the straw-coloured is generally the lightest, and the white the heaviest of all.

The skins should be even, and of all an equality, which, if they were not so united; otherwise we may with justice suspect that it is refuse silk, and cannot be equally drawn out and spun, for one thread will be stronger than the other, which is labour and loss. It will also be requisite to search the bale more than once, and take from out of the parcels a skin to make an essay; for unless it is known by trial, there is the greatest danger of being cheated in this commodity. To wind silk from all the balls, two machines are necessary; the one a furnace, with its copper; the other a reel, or frame, to draw the silk. The winder then, seated near the furnace, throws into the copper of water over the furnace (first heated and boiled to a certain degree, which custom alone can teach) a hundred or two of balls, which have been first well purged of all their loose furry substance. She then stirs the whole very briskly about with birchen rods, bound and cut like brushes, and when the heat and agitation have detached the ends of the silks of the cocoons, which are apt to catch on the rods, she draws them forth, and joining ten or twelve, or even fourteen of them together, she forms them into threads, according to the size required to the works they are destined for: eight ends sufficing for ribbons; and velvets, &c. requiring no less than fourteen. The ends, thus joined into two or three threads, are first passed into the holes of three iron rods, in the top-part of the rod, then upon the bobbins or pulleys, and at last are drawn out to the real itself, and there fastened, each to an end of an arm or bronce of the reel. Thus disposed, the worker giving motion to the real, by turning the handle, guides the threads; substitutes new ones, when any of them break, or any of the balls are wound out; strengthens them, where necessary, by adding others; and takes away the balls wound out, or that, having been pierced, are full of water.

In this manner, twos persons will spin and reel three pounds of silk in a day, which is done with greater dispatch than is made by the spinning-wheel or distaff. Indeed, all silks cannot be spun and reeled after this manner; either because the balls have been perforated by the silkworms themselves, or because they are double, or too weak to bear water; or because, &c. Of all these together, they make a particular kind of silk, called fioretta; which being carded, or even spun on the distaff, or the wheel, in the condition it comes from the ball, makes a tolerable silk.

As to the balls, after opening them with scissors, and taking out the insects (which are of some use for the feeding of poultry), they are steeped three or four days in troughs, the water of which is changed every day to preserve the skin. On these cards, they are well softened by this soaking, and cleared of that gummy matter the worm had lined the inside with, and which renders it impenetrable to the water, and even to air itself, they boil them till an hour in a lye of ashes, very clear and well strained; and after washing them out in the river, and drying them in the sun, they card and spin them on the wheel, &c. and thus make another kind of fioretta, somewhat inferior to the former.

As to the spinning and reeling of raw silks off the balls, such as they are brought from Italy and the Levant, the first is chiefly performed on the spinning-wheel; and the latter, either on hand-reels, or on reels mounted on machines, which serve to reel several skins at the same time.

As to the milling, they use a mill composed of several pieces, which may mill two or three hundred bobbins at once, and make them into as many skins.

For spinning of silks, see DYING.

SILPHIUM, a genus of plants belonging to the class of syngenesia, and to the order of polyagania necessaria; and in the natural system arranged under the 4th order, composite. The receptacle is paleaceous; the pappus has a two-borner margin, and the calyx is squamous. There are eight species: the lacinatum, terebinthinum, perforatum, con- natum, astericum, trifolium, arboresum, and trifoliatum. The first six of these are natives of North America.

Several of the spilix are of an entirely oval outline: of this kind is the S. thoracica, which is easily distinguishable by its red thorax, every other part of the animal being coal-black: it is about half an inch in length.

Silpha strata is of similar size, but totally black, and has the wing-sheaths marked by three rising lines: its larva, which may be found in gardens, is of a lengthened shape and of a black colour. See Plate Nat. Hist., figs. 301 and 302.

SILVER, in natural history, is a metal of a fine white colour, without either taste or smell; and in point of brilliance perhaps inferior to none of the metallic bodies, if we except polished steel. Its hardness is 7. When melted, its specific gravity is 10.475; when hammered, it is capable of being shaped into thin sheets, and, in the form of a thin leaf, into the form of a bowl or vessel of any shape, by means of a hammer, as thin as skin, and capable of being bent into any form. Its ductility is equally remarkable: it may be drawn out into wire much finer than human hair; so fine, indeed, that a single grain of silver may be extended about 400 feet in length. Its tenacity is such, that a wire of silver 0.078 inch in diameter is capable of supporting a weight of 187.133bs. without breaking.
Silver melts when it is heated completely red hot; and while melted, its brilliancy is much increased. According to the calculation of Bergman and Mortimer, its fusing point is 1084° of Fahrenheit. It continues melted at 289°, and requires a much greater heat to bring it to fusion. If the heat is increased after the silver is melted, the liquid metal boils, and may be volatilized; but a very strong and long-continued heat is necessary.

When cooled slowly, its surface exhibits the appearance of crystals; and if the liquid part is still, it is poured out as soon as the surface congeals, pretty large crystals of silver may be obtained. By this method Timlet, and Mongez, junior, obtained it in four-sided pyramids, both insulat in and in groups.

Silver is not oxidized by exposure to the air; it gradually, indeed, loses its lustre, and becomes tarnished; but this is owing to a different cause. Neither is it altered by being kept under water. But if it is kept for a long time melted in an open vessel, it gradually attracts the oxygen from the atmosphere, and is blackened by it. Moreover, by exposing silver 20 times successively to the heat of a porcelain furnace, obtained a glass of an olive-green colour. Nay, if the heat is sufficient, the silver even takes fire and burns like other combustible bodies. Van Marum, in his machine pass through a silver wire; the wire exhibited a greenish-white flame, and was dissipated into smoke. Before a stream of oxygen and hydrogen gas, it burns rapidly, with a light-green flame.

The oxide of silver, obtained by means of heat, is of a greenish or yellowish grey colour; and is easily decomposed by the application of heat in close vessels, or even by exposing it to the light. When silver is dissolved in nitric acid, and precipitated by lime water, it falls to the bottom under the form of a powder, of a dark-greenish brown colour. From the experiments of Wenzel and Berg- man it followed, that the greenish or yellowish, grey oxide is composed of about 90 parts of silver and 10 of oxygen. When this oxide is exposed to the light, part of its oxygen is separated, as Scheele first ascertained; and is converted into a black powder, with but a very small portion of oxygen, and may be considered as silver reduced. By exposing the solution of silver in nitric acid to sunshine, the silver precipitates in the form of a flesh-brown powder.

Neither carbon nor hydrogen has been combined with silver; but it combines readily with sulphur and phosphorus.

1. When thin plates of silver and sulphur are laid alternately above each other in a crucible, they melt readily in a low red heat, and form sulphuric silver. It is of a black or very deep violet colour; brittle, but capable of being cut with a knife; often crystallized in small needles; and much more fusible than silver. If sufficient heat is applied, the sulphur is slowly volatilized, and the metal remains in a black powder, which is very difficult to determine the proportion of the ingredients which enter into the composition of this substance, because there is an affinity between silver and its sulphuret, which disposes them to combine readily. The greatest quantity of sulphur which a given quan-

ity of silver is capable of taking up, is, according to Weazel, 1/13.

It is well known, that when silver is long exposed to the air, especially in frequented places, as churches, theatres, &c., it acquires a covering of a violet colour, which deprives it of its brilliancy. This covering, which forms a thin layer, can only be detached from the silver by beating it, or breaking it in pieces with a hammer. It was examined by Mr. Proust, and found to be sulphide of silver.

2. Silver was first combined with phosphorus by Mr. Pelletier. If one ounce of silver, one ounce of phosphoric glass, and two draughts of charcoal, are mixed together, and heated in a crucible, the phosphuret of sulphur is formed. It is of a white colour, and appears granulated, or crystallized.

It breaks under the hammer, but may be cut with a knife. It is composed of four parts of silver and one of phosphorus. Heat decomposes it by separating the two metals. Peltier has observed, that silver in fusion is capable of combining with more phosphorus than solid silver: for when phosphuret of silver is formed by projecting phosphuret into melted silver, after the crucible has taken from the fire, a quantity of phosphorus is emitted the moment the metal congeals.

Silver does not combine with the simple incombustibles.

Silver combines readily with the greater number of metallic bodies.

1. When silver and gold are kept melted together, they combine, and form an alloy composed, as Homberg ascertained, of one part of silver, and five of gold. He kept equal parts of gold and silver in gentle fusion for a quarter of an hour, and found, on breaking the crucible, the uppermost of which was pure silver, the underneath the whole gold combined with 1/5 of silver. Silver, however, may be melted with gold in almost any proportion; and if the proper precaution be employed, the two metals remain combined together.

The alloy of gold and silver is harder and more sonorous than gold. Its hardness is a maximum when the alloy contains two parts of gold and one of silver. The density of these metals is but little increased; but the colour of the gold is much altered, even when the proportion of the silver is small; one part of silver produces a sensible whiteness in twenty parts of gold. The colour is not only pale, but it has also a very sensible greenish tinge, as if the light reflected by the silver passed through a very thin covering of gold. This alloy being more fusible than gold, is employed to solder pieces of that metal together.

2. When silver and platinum are fused together (for which a very strong heat is necessary), they form a mixture, not so ductile as silver, but harder and less white. The two metals are separated by keeping them for some time in the state of fusion; the platinum sinking to the bottom from its weight. This circumstance would induce us to suppose that there is very little affinity between them.

The affinities of silver, and its oxides, are placed by Bergman in the following order:

Silver.

Silver, fulminating. See Fulmination.

Silver-leaf, that beaten out into fine leaves for the use of the gilders, which is performed in the same manner as gold-leaf.

Silver-wire, that drawn out into fine wires for the use of the masons, which see the articles Gold-wire, and Wire-drawing.

Silver, shell, is prepared of the shreds of silver-leaves, or of the leaves themselves, for the use of painters, after the same manner as shell-gold. See Gold.

Silvering. The art of silvering wood, &c., is performed in the same manner as gilding, making use of silver instead of gold leaf.

To silver copper or brass, clean the metal with aqua fortis, by washing it lightly, and then throwing it in water; or by scouring it with salt and tartar with a wire brush. Dissolve some silver in aqua fortis, and put pieces of copper into the solution; this will throw down the silver in a state of metallic powder. Take 20 gr. of this powder, and mix with it two grains of tartar, the same quantity of common salt, and half a drachm of alum; rub the articles with this composition till they are perfectly white, then brush it off, and polish them with leather.

To silver the dial-plates of clocks, scales of barometers, &c., take an ounce of silver lace, add to it an ounce of double-refined aqua fortis, put them into an earthen pot, and place them over a gentle fire till all is dissolved, which will happen in about five minutes; then take them off, and mix it in a pint of clear water, after which, pour it into another clean vessel, to free it from grit or sediment; then add a spoonful of common salt; and the acid, which has now a green tinge, will immediately let go the silver particles, which form themselves into a white curd; pour off the acid, and mix the curd with two ounces of salt of tartar, half an ounce of whitening, and a large spoonful of salt, more or less, according as you find it for strength. Mix it well up together, and it is ready for use.

Having well cleared the brass from scratch es, rub it over with a piece of old hat and rottenstone, to clear it from all greasiness, and then rub it with a cloth wetted with water by your hand; take a little of the beforementioned composition on your finger, and rub it over where the salt has touched, and it will adhere to the brass, and completely silver it. After which, wash it well with water, to take off
what aqua fortis may remain in the composition; when dry, rub it with a clean rag, and give it one or two coats of varnish. This silver is not durable, but may be improved by heating the article, and repeating the operation till the covering seems sufficiently thick.

Silver plating. The coat of silver applied to the surface of the copper by the methods mentioned above, is very thin, and is not durable. A more substantial method of doing it is as follows. Take small pieces of silver and copper, and tie them together with string, so as to form a little borbax between. The proportion of silver may be to that of copper, a 1 to 12. Put them into a white heat, when the silver will be firmly fixed to the copper. The whole is now made to pass between rollers till it is of the required thickness for manufacturing the articles required.

SILURUS, a genus of fishes of the order amphibians. The generic character is, head large, depressed; mouth wide, bearded by longer, lateral, and a row of small teeth on the upper lip. A single dorsal fin, sometimes preceded by a small, first ray of the pectoral fins, or of t.e first dorsal fin, toothed backwards. There are 28 species.

1. Silurus glanis, European silure. The great or common silure may perhaps be considered the representative of all European river fishes; growing to the length of eight, ten, or even fifteen feet, and to the weight of three hundred pounds. Its more general length, however, is from two to three or four feet. The head is broad and depressed; the body thick and of a lengthened form, with the abdomen very thick and short. It is a fish of a remarkably inert or sluggish disposition, being rarely observed in motion, and commonly living by itself in the soft bottom of the rivers it frequents, under the projecting roots of trees, rocks, logs, or other substances. In this situation it remains, with its wide mouth half-open, gently moving about the long cirri or tentacles situated on each side the jaws; which the smaller fishes mistaking for worms, and attempting to seize, become a ready prey to the sluggish silure. The usual colour of this species is dark olive, variegated with irregular spots of black; the abdomen and lips being of a pale flesh colour, and the fins tinged with violet. It is an inhabitant of the larger rivers of Europe, as well as some parts of Asia and Africa; but appears to be most plentiful in the north of Europe. It is in no very high estimation as a food, the flesh being of a somewhat glutinous nature; but, from its cheapness, is in much request among the inferior ranks, and is eaten either fresh or salted: the skin also, which is smooth, and destitute of apparent scales, is dried and stretched, and after rubbing with oil, becomes of a horny transparency and strength, and is used in some of the northern states of glass window. The silure is not a very prolific fish; depositing but a small quantity of spawn, consisting of large globules or ova: these, as well as the newly hatched young, are frequently found, along with many smaller fishes, in the silure, and thus the great increase of the species is prevented. The ova, according to Dr. Bouch, usually hatch in the space of seven or nine days from their exclusion.

2. Silurus coelestis, electric silure. Length about twenty inches; head and fore-parts very broad and depressed; on the upper lip two cirri; on the lower four; teeth small and numerous. Native of the African rivers; observed by Forskal in the Nile: possesses a degree of electric or galvanic power, but in a much smaller degree than the torpedo.

SILURUS caspius, cat silure. Length about two feet; form rounded and thick; colour dusky above, pale flesh-colour beneath; head round; mouth very large; on the upper jaw, beneath each eye, a very long beard; on the lower jaw four short beards; first dorsal fin small; caudal fin forked; all the fins, with the rest of the fins small and red; tail forked. Inhabits the sea and rivers of North America, preying on all kinds of smaller fishes; and not sparing even those of its own kind, in taste resembles an eel, and is much esteemed by the Americans: is a fish of slow motion, like the European silure.

4. Silurus costatus is an inhabitant of South America and India. See Plate Nat. Hist. fig. 360.

SIMIA, apa, a genus of quadrupeds of the order primates. The Libian generic character is, front teeth in each jaw four, placed near together; canine teeth solitary, longer than the others, distant from the remaining teeth, or grinders; grinders obtuse. This genus is divided into four sections, of which there are about 70 species, viz. 1. Apes, or such as are destitute of a tail. 2. Baboons, or such as have very muscular bodies, and whose tails are commonly long, slender, and flexible; or, lastly, apas, or monkeys, with what are termed prehensile tails, viz. such as can, at pleasure, be twisted round any object, so as to answer the purpose of an additional hand to the animal.

Of the whole genus, or the monkey tribe in general, it may be observed, that the baboons are commonly of a ferocious and sullen disposition. The larger apes are also of a malignant temper, except the orang otan and the gibbons. The monkeys properly so called, are very various in their dispositions; some of the smaller species are lively, harmless, and entertaining; while others are as remarkable for the mischievous malignity of their temper, and the capricious uncertainty of their manners.

It may not be improper here to observe, that it is no easy task to determine with exact precision the several species of this extensive genus; since, exclusive of the varieties in point of colour, they are often so nearly allied as to make it difficult to give real distinctive characters. The most remarkable species are:

APES.

1. Simia satyris, orang otan. Of these singular animals, the species which has most excited the attention of mankind is, the orang otan, or, as it is sometimes called, the satyr, great ape, or man of the woods. It is a native of the warmer parts of Africa and India, as well as of some of the Indian islands, where it re-ites principally in woods, and is a common sight among the inhabitants of that genus, on fruits. The orang otan appears to admit of considerable variety in point of colour, size, and proportions; and there is reason to believe, that, in reality, there may be two or three kinds, which, though nearly approximated as to a general similitude, are yet specifically distinct. The specimens imported into Europe have rarely exceeded the height of two or three feet, and were supposed to be young animals; but it is said that the full grown ones are, at least, six feet in height. The general colour of these animals is reddish brown; in some ferruginous or reddish brown, and in others coal-black, with the skin itself white. The face is bare; the ears, hands, and feet, nearly similar to the human, and the whole appearance such as to exhibit the most striking approximation to the human figure. The likeness, however, is only a general one; and the structure of the hands and feet, when examined with anatomical exactness, seems to prove, in the opinion of those most capable of judging with accuracy on the subject, that the animal was principally designed by nature for the quadrupedal manner of walking, and not for an upright posture, which is only occasionally assumed, and which, in those exhibited to the public, is, perhaps, rather owing to instruction than truly natural. The count de Buffon, indeed, makes it one of the distinctive characters of the real or proper apes (among which the baboons and orang otans are included) to walk erect on two legs only; and it must be granted, that these animals support an upright position much more easily and readily than most other quadrupeds, and may probably be very often seen in this attitude even in a state of nature.

The manners of the orang otan, when in captivity, are gentle, and perfectly void of that disgusting ferocity so conspicuous in some of the larger baboons and monkeys. It is docile, and may be taught to perform, with dexterity, a variety of actions in domestic life. Thus it has been seen to sit at table, and, in its manner of feeding and general behaviour, to imitate the company in which it is placed: to pour out tea, and drink it, without awkwardness or constraint; to prepare its bed with great exactness, and to dispose itself to sleep in a proper manner. Such are the actions recorded of one which was exhibited in London in the year 1738: and the count de Buffon relates that of an orang otan of the same species, which he saw at Paris, Dr. Tyson, who, about the close of the last century, gave a very exact description of a young orang otan, then exhibited in the metropolis, assures us, that, in most of his actions, it seemed to display a very high degree of sagacity. "The most gentle and loving creature that could be. Those that he knew a slip-board he would come and embrace with the greatest tenderness, opening their bosoms, and clasping his hands about them; and, as I was informed, though there were monkeys abroad, yet he was observed he never would associate with them, and, as if nothing to do, would always avoid their company."

But however docile and gentle when taken young, and instructed in its behaviour, it is said to be possessed of great ferocity in its native state, and is considered as a dangerous animal, capable of really overpowering the most powerful of our species. Its ferocity is in direct ratio to its strength, and for this reason it is rarely to be obtained in its full-grown state; the young alone being taken. A few years past, the hand of a supposed full-grown orang otan was brought from Sierra Leone, which, from its
SINIA.

On its first arrival it had but very little hair, except on its body and arms; but on the approach of winter it became extremely well covered; the hair on the back being three inches in length. The whole animal then appeared of a chestnut-colour; the skin of the face, &c. was of a mouse-colour, but about the eyes and round the mouth of a dull flesh-colour.

It came from the island of Borneo, and was deposited in the museum of the prince of Orange.

Upon the whole, it appears clearly that there are two distinct species of this animal, viz. the pongos, or more and black orang otan, which is a native of Africa, and the reddish brown or chestnut orang otan, called the jooke, which is a native of Borneo and some other Indian islands. This latter, as appears from a collection of most of the specimens which have been surveyed with the necessary degree of exactness, is distinguished by having no nails on the great toes; whereas in the pongo, or black species, they are conspicuous.

2. Sinia lar, or long-armed ape. This is a species of a more deformed appearance than the oran otan, and is distinguished by the excessive length of its arms, which, when the animal stands upright, are capable of touching the ground without raising its feet. It is a native of India and some of the Indian islands, and grows to the height of four feet or more. Its colour is black; but the face is commonly surrounded by a whitish beard.

Notwithstanding the apparent ferocity of the gibbon, and the deformity of its figure, it is a quiet and gentle animal, and is not likely to do any injury to man. It is a native of the islands of Borneo, and is of small size, and are of a hazel colour. The hands and feet have strong black claws; but the thumbs of the hands have rounded nails. The tail is very short. It is ferocious in its manners, and its appearance is at once grotesque and terrorizing.

The region surrounding the tail, to a considerable distance on each side, is perfectly bare and callos, and of a red colour. This is also common, in a greater or smaller degree, to the rest of this division. It is a native of the islands of Borneo.

5. Sinia mormon, variegated baboon. This is at least equal in size, if not superior, to the former, and, when in an upright posture, is about five feet high. It is the most remarkable of the whole genus for brilliancy and variety of colour. The general tinge is a rich and very deep yellowish-brown; the hairs, if viewed near, appearing speckled with yellow and black. The form of the face is long, with the snout ending somewhat abruptly; the whole length of the nose, down the middle, is of a deep blood-red; but the parts on each side are of a fine violet-blue, deeply marked by several oblique furrows. The under part is of a pure white, or whitish-yellow. It is a native of the interior parts of Africa; but it is said to have been also brought from India.

The variegated baboon is of a fierce disposition, and is of a much larger size than the former. Its voice somewhat resembles the slight roar of a lion; it is a rare species, and is not often imported into Europe.

6. Sinia malinon, malimon. The species between these two and the former are commonly confounded. It is described by the count de Buffon under the name of mandrill. It is an active animal, and seems far less inoffensive and malignant than the rest of the baboons. The general likeness which it bears to the former species is such as to give the idea of the same animal in a less advanced state of growth, and with less brilliant colours; the nose, instead of being red on the sides, is white, or pale coloured; but the sides are blue and tawny, as in the former species. This baboon is not uncommon in exhibitions of animals. Its length from nose to tail is about two feet. Tail exactly as in the former.

The next division of the baboons consists of such as have long tails. Of these the chief is the

7. Sinia lamadryas, dog-faced baboon. This species is of an elegant colour, composed of a mixture of grey and brown, the hair appearing as if speckled. It is a very large animal, at least equal, if not superior, in size to the common brown baboon and the monkey, and extremely numerous. It has a vast quantity of flowing hair on each side the head, as well as round the shoulders, spreading in such a manner as to give the appearance of a short cloak or mantle. The whole face is naked, and of a flesh-colour, more or less deep in different individuals. The tail is almost the length of the body, and is commonly a little tuffed at the end. The nails on the hands and fore-feet are flat; those on the hind-feet resemble the nails of the common baboon, and a rare species of the same genus. The tail is compared with the common baboon, and is a native of the hottest parts of Africa and Asia, where it is said to reside in vast troops, and to be very fierce and dangerous. There is a wonderful degree of sagacity in the coun-
disposition of the hair on the top of the head, which spreads out in a circular direction, somewhat in the manner of a Chinese cap, is a native of Ceylon, and is about the size of a cat. Its general colour is a pale yellowish-brown, pale ochre, and the ears are black. The face is very dusky, and sometimes the general tinge of the animal is dusky-ferruginous. This species is easily distinguished when seen in a healthy state: the hair on the top of the head resembling that of a boy; as if parted in the middle, and lying smooth over the head. They are said to inhabit the woods in great troops, and to be very destructive to such gardens and plantations as he within reach of their retreats. The tail in this species is very long: the nails of the thumbs are round; the rest long.

12. S. petrannis. Vaulting monkey. This is described by Mr. Allman in his edition of Buffon's Natural History of Quadrupeds. It is said to be somewhat more than a foot high, and the tail about twenty inches long. The upper parts of the animal are of a dark olive-coloured, owing to a mixture of olive-green and black hair, and the same is the case with the white. The face is indicated by a fine long chevelure of grey-brown hair, and a large beard of fair grey. The chevelure or spreading hair round the face stretches upwards over the eyes and forehead, as in particular that of the head is not the same in the short-tailed, nor the long-tailed baboon, to which, indeed, from the figure as well as description, it appears so extremely similar, that it might well pass for a variety of the same animal.

M. de l'Isle.

Diana. Spotted monkey. Mr. Pennant describes this species as of a middling size, and of a reddish colour on the upper parts, and as siveen, and marked with white specks; the belly and chin whitish; the tail very long. The Limarcan description differs. Limarcan says the animal is of the size of a large cat, and is black, spotted with white; the hind part of the back ferruginous; the face black; from the top of the nose a white line, passing over the eye, and arched on the cheek, which arches the mouth; (this circumstance was probably the reason of the Limarcan name Diana, by which he has chosen to distinguish the animal) the beard pointed, black above, white beneath; a kind of hair on the crown; the hair of the beard and throat white; from the scull the hair of the face white, when passing through the eyes, the nose, and mouth, and over the teeth, it is a dull flesh-colour; the cheeks are surrounded by long white hairs, inclining to yellow; the forehead is grey, and above the eyes, from car to ear, extends a black line. The upper part of the animal is dusky and tawny; the breast, belly, and loin, are of the same colour; whenever the animal is alarmed, its face is covered with a tawny mane. The size is greater in the thickness of the limbs and arms black; hands and feet black and naked: the tail of a cinnamon brown. On each side the base of the tail is commonly an oval white spot. This species inhabits Barbary, Athiopia, and other parts of Africa.

14. S. nasina. Proboscis monkey. Amongst the whole tribe of monkeys this perhaps may be considered as the most singular in its peculiar long nose, being of such length and form as to present, especially in a profile view, an appearance the most grotesque imaginable; and indeed from an inspection of the figure alone, one would be apt to imagine that it must have been designed for a caricature of a monkey. The animal, however, is preserved in the royal cabinet at Paris, and was first described by Mons. D'Aubenton. It is a large species, measuring from the nose to the tail, which is more than two feet long. The face has a kind of curved form, and is of a brown colour, and marked with blue and red; the ears broad, thin, naked, and hid within the hair. The size of the nose is most singular, being divided almost into two lobes at the tip; a longitudinal furrow running along the middle. It is said to be found chiefly in Cochinchina, and to grow to a very large size. It is sometimes seen in great troops, and is considered as of a ferocious disposition. It feeds on fruits. Its native name is khai do, or great monkey.

15. S. nemaua. Cochinchina monkey. The douc or Cochinchina monkey is a very large species, measuring at least two feet from the nose to the tail. The face is flat, and of a yellowish-brown colour, as are also the ears; across the forehead runs a narrow dusky band. The back, the under parts of the body, and sides, are of a yellowish grey; the lower part of the arms and tail are white; the feet dusky. It is a native of Cochinchina, and also of Madagascar. It is said that a bezoar is more frequently found in the stomach of this species than of almost any other. When in an upright posture this animal measures three and a half or four feet in height, being nearly of the size of a Barbary ape. This species seems considerably allied in its general form and colours to the preceding, but is distinguished in other parts, so as to form a large mode like that of a lion; near the face this mane is of a redish colour, and grows paler as it recedes from the cheeks; the face itself is of a dusky purple; the ears are large and fat; the hands and feet are also naked, and of the same dull purple colour as the face; the claws are small and sharp; the tail is very long, and rather bushy at the extremity. It is a native of Guiana, and is a lively, active species, and gentle in a state of confinement.

SIEI.

16. S. rosalis. Silky monkey. This species is said to be of the size of a fox, and of a black colour, with smooth glossy hair; round, beard beneath the chin and brest, and throat; the fore limbs are of the same colour, and the hind parts are black; the hands and feet are also black, and of the same dull purple colour as the face; the claws are small and sharp; the tail is very long, and rather bushy at the extremity. It is a native of Guiana, and is a lively, active species, and gentle in a state of confinement.

SIEI.

17. S. costae. Preacher monkey. This species is said to be of the size of a fox, and of a black colour, with smooth glossy hair; round, beard beneath the chin and breast, and throat; the fore limbs are of the same colour, and the hind parts are black; the hands and feet are also black, and of the same dull purple colour as the face; the claws are small and sharp; the tail is very long, and rather bushy at the extremity. It is a native of Guiana, and is a lively, active species, and gentle in a state of confinement.

SIEI.

18. S. paniscus. Four-fingered monkey. This animal is distinguished by the gracility of its body and limbs; its uniform black colour, except on the face, which is of a dark greyish-brown, and a yellowish-brown on the fore feet, instead of which are very small projections or appendages. It is one of the most active and lively of animals, and is besides a gentle and tractable disposition in a state of confinement. It inhabits the woods of South America; associating in great multi-
tudes; assailing such travellers as pass through their haunts with an infinite number of sportive and mischievous gambols; cherishing and throwing down dry sticks, swinging strings, all tails from the birch, and endeavouring to intimidate the passengers by a variety of menacing gestures.

SIMILAR, in arithmetic and geometry, the same with like. In mathematics, similar parts have the same ratio to their wholes; and if the wholes have the same ratio to the parts, the parts are similar. Similar angles are also equal. In solid angles, when the planes under which they are contained are equal, both in number and magnitude, and are disposed in the same order, they are similar, and consequently equal. Similar arches of a circle are such as are like parts of their whole circumferences, and consequently equal. Similar plane numbers are those numbers which may be ranged into the form of similar rectangles, that is, into rectangles whose sides are proportional; such are 12 and 48, for the sides of 12 are 6 and 2, and the sides of 48 are 12 and 4; but 6:2::12:4, and therefore these numbers are similar. Similar polygons are such as have their angles equally. and the sides about those angles proportional. Similar rectangles are those which have their sides about the equal angles proportional. Hence 1. All squares are similar rectangles. 2. All similar rectangles are to each other as the squares of their homologous sides. Similar right-lined figures are such as have equal angles, and the sides of the former are proportional to the sides of the latter. Similar segments of a circle are such as contain equal angles. Similar curves: two segments of two curves are called similar, if, any right-lined figure being inscribed within one of them, we can inscribe always a similar right-lined figure in the other. Similar conic sections: two conic sections are said to be similar, when any segment being taken in the one, we can assign always a similar segment in the other. Similar diameters of two conic sections: the diameters in two conic sections are said to be similar, when they make the same angles with their ordinates. Similar solids are such as are contained under equal angles, and have all their sides proportional. Similar triangles are such as have their three angles respectively equal to one another. Hence, 1. All similar triangles have the sides about their angles proportional. 2. All similar triangles are to one another as the squares of their homologous sides.

SIMILAR FIGURES, in geometry, such as have their angles respectively equal, and the sides about the equal angles proportional.

SIMONIANS, in church history, a sect of antient christians, so called from their founder Simon or the magician. The heresies of Simon Magus were principally his pretending to be the great power of God, and thinking that the gifts of the Holy Ghost were venal.

SIMONY, is the corrupt presentation of any one as ecclesiastical benefice, for money, gift, reward, or benefit.

By one of the canons of 1603, every person before his admission to any ecclesiastical promotion, shall, before the ordinary, take an oath, that he has made no simoniacal contract, promise, or payment, directly or indirectly, by himself or any other, for the obtaining of the said promotion; and that he will not afterwards perform or satisfy any such kind of payment, contract, or promise, by any other without his knowledge or consent.

To purchase a presentation, the living being actually given, and the sale of the same presentation is; but it is void by the common law. 2 Black. 22.

A bond of resignation is a bond given by the person intended to be presented to a benefice, with condition to resign the same, and it is void unless of the special one is to resign the benefice in favour of some certain person, as a son, kinsman, or friend of the patron, when he shall be capable of taking the same. By a general bond within three months after being requested, to the intent that the patron might present his son or other heir to a benefice, and the judgment was affirmed in the exchequer-chamber; for a man may, without any colour of simony, bind himself for good reasons, as if he takes a second benefit, or that he is not interested in the patronage, or that the patron presents his son, to resign; but if the condition had been to let the patron have a lease of the glebe or tithes, or to pay a sum of money, it would have been simoniacal.

SIMPLICITY in music, a pure, unmixed, single sound or note, which shall not allow that there is, musically speaking, any such sound in nature; but assert on the contrary that every sound which is produced is at least accompanied with its twelfth and seventeenth.

SIMPLE, in pharmacy, a general name given to all herbs or plants, as having each its particular virtue, whereby it becomes a simple remedy.

SIMPLE SOUNDS, see Elements.

SIMPLICITY, in composition, a natural unadorned melody, or incomplex combination of parts, in which the composer endeavours, rather by the force of his genius and feeling than the refinement of science, to produce his own ideas and emotions, without disturbing the purity of the text.

SINAPIS, mustard, a genus of plants belonging to the class of tetracyanids, and to the order of siliqueae, and in the natural system ranged under the 39th order, siliqueae. The calyx consists of an expanding strap-shaped deciduous leaves; the unites or branches of the petals are straight; two glands between the shorter stamina and pistillum, also between the longer and the calyx. There are 10 species, three of them natives of Britain.

1. The white, or white mustard, which is generally cultivated as a salad-herb for winter and spring use.
2. The nigra, or common mustard, which is frequently found growing wild, and is but inferior to the white, but is also cultivated in fields for the seeds, of which the sauce called mustard is made.
3. The arvensis grows naturally on arable land in many parts of Britain. The seed of this is commonly sold under the title of Durham mustard seed. Of this there are two varieties.

INCIPUT, in anatomy, the fore part of the head, lying from the forehead to the coronal suture. S I N, or right siste of an arch. See Tri-

IONOMETRY. SINE-CURE, is where a rector of a parish has a vicar, a brother endowed and charged with the cure, so that the rector is not obliged either to do duty or residence.

SINE-DIE, without day, in law, a term frequently used in our proceedings at common law; as when judgment is given against the plaintiff, he is said to be in misericordia pro fabo clamarque suo; so when judgment passes for the defendant, it is entered ex inde sine, being as much as to say, he is discharged, or dismissed the court.

SINISTER. See HERALDRY.

SINKING FUND, in political economy, a portion of the public revenue appropriated to the reduction or discharge of the public debts, and consisting of sums adopted in other countries long before it was resorted to in Great Britain, a provision of this kind had appeared necessary at a much earlier period, and had been established in France, to which country it was introduced under the name of the state in 1682. These funds were both formed by reducing the interest payable on the public debts, and appropriating the annual sum thus saved to the gradual discharge of the principal.

In the reign of king William, when the mode of providing for extraordinary expenses by incurring public debts, which has become so general, was first adopted in this country, the tax on which, money was borrowed, generally produced much more than sufficient to pay the annual interest, and the surplus was applied in sinking or discharging the principal, which was generally effected in a few years. Had this plan been pursued, there never could have been any very great accumulation of public debts; but, as the expenditure increased, and the necessity of loans of still greater amount became more frequent, the mode of proceeding found itself so perfectly diffused to provide effectually for the yearly interest of the sums thus borrowed; and the repayment of the principal was either put off to a distant period, or left without any provision to the chance of more flourishing times.

Some of the effects of an accumulating public debt soon became evident in the discount at which all government securities sold, and in the difficulties experienced in providing for the annual expenditure; the propriety of reducing, and even of wholly discharging, the principle, was acknowledged; and the plan of a sinking fund very similar to that which was afterwards adopted, was recommended in a pamphlet published in 1701. In 1713 Mr. Archibald Hutcheson presented to George I. a plan for the public debts. In 1715 different projects for this purpose were published by Edward Leigh, Mr. Avill, and others. And in 1717 a plan for the gradual discharge of the debt was actually adopted, which was afterwards generally known by the appellation of the sinking fund.

The country had been engaged in an expensive war during nearly the whole of the reign of queen Anne; and it had been found impracticable to obtain the large sums required without paying the interest, a very high interest; but upon the return of peace the current rate of interest lowered considerably, which proceeded in part from a real increase of the national capital, as well as from proceedings to governments of that amount, being no longer necessary. It was therefore deemed a proper opportunity for effecting a reduction of the high interest payable to the public creditors, and of establishing a sinking fund for reducing by degrees the debts of the nation. Accordingly, on the 20th of May, 1717, general Stanhope, who was then first lord of the treasury, and chancellor of the exchequer, submitted to parliament the terms of a proposition with the bank of England and the South Sea company, by which the interest was to be reduced from 6 to 5 per cent, on the capitals of these corporations, who were the principal public creditors, and who were likewise furnished money, if it should be necessary, for paying off such individuals as should not agree to a similar reduction of the interest payable to them. The total annual interest saved to the government by this arrangement was no less than 328,560l. 12s. 7d.

The different funds on which most of the public debts had been charged were consolidated; and the produce of all the permanent taxes was distinguished into only three funds, called the aggregate fund, the South Sea fund, and the general fund. From these three funds the interest of all the public debts was payable; and the excess or overplus beyond the payments with which each fund was charged, was to be appropriated, reserved, and applied, to reducing the principal, and to the payment of the annual interest of the national debts and incumbrances, as were incurred before the 25th day of December 1716, and are declared to be national debts, and were provided for by act or acts of parliament, to be discharged therewith, or out of the same, and to or for none other use, intent, or purpose, whatsoever.

This constituted the sinking fund; and as the plan originated while sir Robert Walpole was in office for the last time, he is much honored as the father of it: but it is evident that it required no invention, but little judgment, to adopt a measure which had been found efficacious in other countries, which had been publicly recommended some years before, and the utility of which was so obvious, that not to have adopted it, when the reduction of interest rendered it so practicable, and when an example had been set in the establishment of the aggregate fund, would have been inexusable. It was a case of appropriating generally the surplus of funds which were before established, to the uses to which the greater part had before been specifically appropriated.

For a few years the fund was strictly applied to the purposes for which it was established; and so well were its nature and importance then understood, that rather than encroach upon it, money was at the same time borrowed for extraordinary expenses. This perseverance was however of no long duration; and in 1722 it was made a collateral security for the interest of a million raised by exchequer bills, which prepared the way for more direct encroachments. In 1728 the sum of 15,144l. was taken from the fund, to make good the loss to the treasury from the reduction of the value of gold coin; and within twelve years from its establishment it was charged with the interest of new loans. In the period of half a million was taken from it towards the supplies, at which time the medium annual produce of the fund for five years had been 1,212,000l. This amount, with its proper increase, would have been sufficient for the discharge of the debt which then existed, but the alienation of it was continued; and Mr. Price has shewn that no greater part of the public debt than about eight millions and a half was reserved from this period to the year 1786; when, in consequence of a new arrangement of the public accounts, the distinction of the different funds above-mentioned was abolished, and the produce of all the permanent taxes included under one general head, called the consolidated fund.

One of the objects of this arrangement was to lay the foundation of a new sinking fund, formed from the general surplus of the revenues of the old fund, in the application of the principle of compound interest. Among those whom Mr. Pitt consulted on this occasion, he particularly sought the advice and assistance of the immortal Mr. Price, who communicated three plans, which he conceived to be best adapted for carrying into execution a measure that he had so often urged in his different publications, particularly before the American war had wrested the public debts to what then appeared to be a hopeless magnitude: it was one of the plans thus communicated, which was afterwards adopted, but with some alterations which considerably affected its efficacy, and still remained necessary to correct. By the act which was passed for carrying this scheme into execution, 20 Geo. 3. c. 31, the annual sum of 1,000,000l. was placed in the hands of commissioners, who are, the speaker of the house of commons, the chancellor of the exchequer, the master of the rolls, the accountant-general of the court of chancery, and the governor and deputy-governor of the bank, for the time being respectively. This sum is paid into the bank in quarterly payments, and to be applied either in paying off such redeemable annuities as were at or above par, or in the purchase of annuities below par, at the market-price. The dividends on the sums redeemed or purche-
ed, with the annuities for lives or terms that should fall in or expire, and the sums which might be saved by any reduction of interest, were to be added to the fund, which was thus to continue increasing till it amounted to four millions a year; and this it was computed would be in about 26 years. To raise upwards of 56 millions of stock would have been redeemed, from which the dividends on such capital as should afterwards be paid off or purchased by the commissioners, with such annuities as might fall in, were to be at the disposal of parliament.

On the 17th of February, 1792, Mr. Pitt proposed that the sum of 400,000£. should be issued in addition to the million, for the purpose of accelerating the operation of this fund; and stated, that in consequence of this and future intended additions, it might be expected that 25 millions of 3 per cent. would be paid off by the year 1800; and that in the year 1808, the fund would amount to four millions per annum, being the sum to which it was intended to go. But the most important provision was a provision, that whenever, in future, any sums should be raised by loans on perpetual redeemable annuities, a sum equal to one per cent. on the stock created by such loan, should be issued out of the produce of the consolidated fund, quarterly, to be placed to the account of the commissioners, who were to keep a separate account of the stock redeemed by this new fund, with the object of avoiding the accumulation of the original fund. By these means the immediate progress of the fund was quickened, and future loans were put into a regular course of redemption.

The indiscriminate restriction of the fund to four millions per annum, was done away by an act passed in 1802, which directed that the produce of the two funds should continue to accumulate, without any limitation as to its amount, and be from time to time applied, according to the former provisions, in the redemption or purchase of stock, until the whole of the perpetual redeemable annuities, existing at the time of passing the act, shall have been completely redeemed or paid off. At the same time the usual annual payment of 200,000£. in aid of the fund, was made a permanent charge, to be issued in quarterly payments from the consolidated fund, in the same manner as the original million per annum. In consequence of these improvements, the increase of the fund has been much greater than it was originally estimated; and its total amount, with the sources from which it arose, was on the 1st of February, 1809, as follows:

| Annual charge, by act of 29 Geo. Ill. | £1,000,000 | 0 | 0 |
| Ditto, 42 Geo. Ill. | 200,000 | 0 | 0 |
| Annuities for 99 and 96 years, as agreed to 1792 | 54,880 | 14 | 6 |
| Short annuities, expired 1787 | 25,000 | 0 | 0 |
| Life annuities, unclaimed and expired | 50,308 | 5 | 7 |
| Dividends on 98, 386, 402£. at 3 per cent. | 2,951 | 592 | 1 | 2 |
| Ditto on 2,617,400£. at 4 per cent. | 104,696 | 0 | 0 |
| Ditto on 142,000£. at 5 per cent. | 7,100 | 0 | 0 |

One per cent. on capitals created since 1793 £3,292,972 1 10

Total £7,996,249 3 1

This sum is exclusive of the fund for the reduction of the public debt of Ireland, funded in Great Britain, which at the above period amounted to 479,337£. 8s., and of the fund for reduction of the imperial debt, which amounted to 53,696£. 15s. 4d.

The commissioners are directed by the act to make their purchases "in equal proportions, as nearly as may be, on every day (Saturdays and Mondays excepted) on which the same shall be transferable." So that they purchase on four days in every week in which there are no holidays. They are empowered to subscribe towards any public loan, to be raised by act of parliament, upon perpetual annuities, subject to redemption, and for the following reasons:

1. To begin the interest of the amounts issued to them, and of the stock purchased to the 1st of February in every year, is to be annually laid before parliament on or before the 15th of February. The purchases, at first, were made in the 3 per cent., probably with the view of redeeming the five per cent. if the state of the public funds should render such a measure practicable, or of inducing the proprietors to agree to a reduction of the interest at the time when they should become redeemable.

2. The progress of the fund from the commencement of its operation on 1st August 1766, to the 1st of February 1806, will appear from the statement of the total amount of the stock redeemed by the commissioners to the latter period.

| Consolidated 3 per cent. annuities | £3,992,421 |
| Reduced 3 per cent. annuities | 31,006,081 |
| Old South Sea annuities | 3,492,000 |
| New South Sea annuities | 2,769,000 |
| Three per cent. | 190,000 |
| Consolidated 4 per cent. annuities | £2,167,400 |
| Navy 5 per cent. annuities | 142,000 |

Total £101,145,802

The total sum which had been paid for this amount of stock, was 62,427,782£. 7s. 10d. the consolidated 3 per cent. having been bought on an average at 61 per cent. and the reduced at somewhat less.

The progress already made by the fund, and the important effect it has had in supporting the value of the government securities at a time when it has been necessary to borrow sums on unprecedented sums in almost every year, sufficiently demonstrate the great utility of this measure. As its increase will be continually augmenting, it will, if steadily persevered in, and faithfully applied, become ultimately capable of discharging a debt of any amount which it is possible to suppose the country will ever be encumbered with.

It has been shown that the fund, including the provision for the reduction of the debt in Ireland, in Great Britain, for the imperial loans, amounts at present to upwards of eight millions per annum; and as the stock has been bought up at little more than 60 per cent. the money has been improved at nearly 5 per cent. interest. It is neither desirable, nor to be expected, that it will always be possible to invest the produce of the fund at this rate of interest; but it will be shewn that if the fund is never diverted from its purpose, its effects will in time be almost omnipotent, particularly when it is considered that the following are the money, and consequently much less than the nominal capital of stock that would be bought up at any of the current prices at which these securities have been for many years past:

Amount to which the present sinking fund of eight millions per annum will accumulate, if improved at 4 or 5 per cent. compound interest.

</table>
When the liquid, after these substances have been separated from it, is concentrated by evaporation, it deposits crystals of acetate of soda. Sinovia, therefore, contains soda. Margueron found that 100 parts of sinovia contain 0.71 of soda.

When strong sulphuric, nitric, nitro, acetic, or sulphurous acid, is poured into sinovia, a number of white flakes precipitate at first, but they are soon re-dissolved, and the viscosity of the liquid continues. When these acids are diluted with five times their weight of water, they diminish the transparency of sinovia, but not its viscosity; but when they are further diluted till their acid taste is just perceptible, they precipitate the peculiar thready matter, and the viscosity of the sinovia disappears.

When sinovia is exposed to a dry atmosphere, it gradually evaporates, and a scaly residuum remains, in which cubic crystals and a white saline efflorescence are apparent. The cubic crystals are muriated of soda. One hundred parts of sinovia contain about 1.75 of this salt. The saline efflorescence is carbonate of soda.

Sinovia soon putsrefies in a moist atmosphere, and during the putrefaction ammonia is exhaled. When it is distilled in a retort, there comes over, first water, which soon putrefies, then water containing ammonia, then empyreumatic oil and carbonat of amonia. From the residuum muriat and carbonat of soda may be extracted by lixiviation. Sinovia is composed of

**SINUATE LEAF.** See Botany. **SINUS.** See Anatomy. **SINUS.** See Surgery. **SIPHON, or SYPHON.** See Hydrostatics.

**SIPHONIATUS, a genus of the tetradria monogynia class and order.** The corolla is one-petalled, very long, funnel-form, inferior; berries four, one-seeded. There are two species, herbs of South America.

**SIPHIÖNIA, a genus of the class and order monoxea monadelphia.** The caulis is one-leaved, no corolla; male anders five; fem. style none; stamin three; caps. tricoceous; seed one. There is one species, a tree of Guiana.

**SIPUNCULUS, or tube-worm.** A genus of insects of the order venae intestinae: the generic character is, body round, elongated; mouth cylindrical at the end, and narrower than the body; aperture at the side of the body, and crooked. There are two species: the S. nudus, inhabits the European seas, under stones, and is eight inches long. The S. saccatus, body covered with a loose skin, and rounded at the lower end: inhabits the Mediterranean and Indian seas.

**SIREN, a genus of amphibia, of the order meutes, of which there are the following species:**

1. **Siren lacertina, or eel-shaped siren:** This species stands easily distinguished in the list of amphibia by the agility of its characters, which are such as to have induced the great Linnaeus to institute for it a new order of amphibia, under the title of meutes; andorder, 

The species of sirens at present to be described is extremely rare; and is found in the spring, and towards the decline of summer, in some particular parts of the above-mentioned lakes, and considered as a full-grown, from about ten to twelve or thirteen inches in length; the largest specimens being near three quarters of an inch in diameter. It is entirely of a pale rose or pinkish-white, or even nodocolour, or even whitish, excepting the three pairs of ramified branched fins on each side the head, which are of a bright red or carmine-colour. Its general shape is that of an eel; the body being cylindric, till towards the end of the tail, where it becomes flat, and is attenuated both above and below into a kind of fatty fin, scarcely distinguishable from the rest of the tail; the skin is everywhere smooth and even; the head of a somewhat depressed form; with a lengthened, obtuse, and whitish nose, and has no external eyes; the mouth is moderately wide, and furnished with a row of very minute teeth; the legs are about 3 of an inch in length, the fore legs being situated, not immediately behind the frontal fins, and the feet furnished with three toes, without any appearance of claws; the hind legs are situated at a great distance backwards, towards the commencement of the tail, and are of the same appearance with the fore legs; but the feet have only two toes, which, like those of the fore feet, are destitute of claws. The motions of the animal, when taken out of the water, are, in general, extremely slow and languid, as is also the case when kept in a vessel of water; but when in its native lake, it is sometimes observed to swim pretty briskly, waving its body in a serpentine direction in the manner of a locust.

3. **Siren pisciformis, fish-formed siren.** This animal in its natural size is supposed to be the native of Mexico, and though perhaps no other than the larva or tadpole of some large American salamander, sea or river, a lively, quick, and curious animal than the siren lacertina.

In its general appearance it bears some resemblance to the larva of the rana paradoxora, but is furnished with gills, opening externally in the upper part of the head, which is very large, and the operculum or external flap is continued from the sides of the head across the throat beneath, so as completely to insulate the head from the breast; the gills themselves consist of four semicircular bones or cartilaginous arches, which are dentilculated or serrated on their internal or concave part, like those of fishes; on the operculum or external flap are situated large very large and elegant branchial fins or ramified parts, divided or subdivided into a vast number of slender or capillary processes. In these particulars it resembles the sire lacertina, except that in that animal the external opening to the gills is very small; the mouth is furnished in front with a row of extremely minute teeth; the tongue is large, smooth, and rounded at the tip; the rictus, or gape, when the mouth is closed, appears considerably larger than that of any other than the sire lacertina; it is situated in a hollow, or valley, surrounded by rocky and woody mountains, in which are vast caverns, and is principally supplied by eight rivulets running into it from the adjoining mountainous region.
ish claws; the fore feet have four, and the hind five toes. Exclusive of the general colour of the animal, the whole body in the minutely examined, appears to be scattered over with very minute white specks, resembling those on the surface of the siren lacerina. This is a very remarkable characteristic, since the body is marked by several strong rugae or furrows, and the spots of the lateral line or sulcus is continued from the gills to the tail.

SIREX, a genus of insects of the hymenoptera order. The generic character is, mouth with one labrum, two maxillae; feelers two, truncated; antennae filiform, with more than twenty-four joints; piercer exerted, stiff, serrated; abdomen sectional, pointed; wings lanceolate, flat in all.

The larvae of these insects are of a lengthened, cylindrical appearance, living in the decayed parts of trees, on the substance of which they feed; the chrysalis, as in the tenthredo, exhibits the limbs of the perfect insect in a contracted state.

The largest species is the srix gigan of Linnaeus, which surpasses a hornet in size, and is principally observed in the neighbourhood of pines and other coniferous trees; it is of a black colour, with the eyes, the base, and the middle third of the abdomen, bright orange yellow; the thorax violet, and the wings of transparent yellowish brown; the sting or a terminal tube is very conspicuous. The larva, which measures about an inch and a quarter in length, is of a yellowish white colour, and oval in shape; at first view it bears some resemblance to the larva of the beetle tribe, but is thinner in proportion, and furnished at the tip of the abdomen with a short black spine or process. It changes to a chrysalis in July, first enveloping itself in a slight silken web of a whitish colour. If the change to chrysalis takes place in summer, the fly proceeds from it in the spaces of about three weeks; but if at the close of autumn, the animal continues in chrysalis the whole winter, emerging in the following spring. The male insect is considerably smaller than the female, and may be further distinguished by the want of the caudal tube or process, so conspicuous in the female insect; the tip of the abdomen is also of a black colour. The eggs, which are deposited by the female in the decayed parts of the tree above mentioned, are very small, and a flattened ovate shape with pointed extremities.

Sirex columbia is an American species, and is distinguished by its black body, marked by testaceous bands.

Sirex pygmaeus is one of the smallest of the European species, being, according to Linnaeus, about the size of a gnat, with a black abdomen, marked by three yellow bands, the middle of which is interrupted. It is found in Sweden. There are seven species.

SIRIUS, the dog-star. See Astronomy.

SIRIUM, a genus of plants belonging to the class of tetraandria and order of monogynia. The calyx is quadriradiate; there is no corolla and the anther is quadrathyllous, and crowning the throat of the calyx; the gemma is below the corolla; the stigma is tridid, and the berry trilocular. There is only one species, the myrtifolium.

SIROCO. The sirocco (so called by the Italians because it is supposed to blow from Syria, and in the south of France the Levant wind) is the most destructive of the harmattan, but differs from it in being extremely insidious. It sometimes blows for several days together, to the great annoyance of the whole vegetable and animal creation; it thickens the air, makes it unfit for vegetation and twelve degrees; it is fatal to vegetation and destructive to mankind, and especially to strangers; it depresses the spirits in an unusual degree; it suspends the powers of digestion, so that those who venture to eat a heavy supper while this wind prevails, are commonly found dead in their beds the next morning, of what is called "an indigestion. The sick, at that afflicting period, commonly sink under the pressure of their diseases; and it is customary in the morning, after this wind has continued a whole night, to inquire who is dead.

We shall now insert an account of this baleful wind, from an interesting work on the present state of Sicily.

"The evil most to be dreaded in traversing these regions is, perhaps, the sirocco, or south wind, which it is imagined blows from the burning deserts of Africa, and is sometimes productive of dangerous consequences to those who are exposed to its fury. During the continuance of this wind all nature appears to languish, vegetation withers and dies, the beasts of the field droop, the animal spirits seem to be much exhausted to admit of the least bodily exertion, and the spring and elasticity of the air appear to be lost. The heat exceeds that of the most fervid weather in Spain or Malta, and is felt with peculiar violence in the city and neighbourhood of Palermo.

"The sensation occasioned by the sirocco wind is very striking and wonderful. In a moment the air becomes heated to an excessive degree, and the whole atmosphere feels as if it was inflamed; the pores of the body seem at once opened, and all the fibres relaxed. During its continuance the inhabitants shut their doors and windows to exclude the air; and where there are no window-shutters, wet blankets are hung on the inside of the window, and the servants are kept continually employed in sprinkling the apartments with water. No creature, whose necessities do not compel him to the exertion, is to be seen while this tremendous wind continues to blow, and the streets and avenues of the city appear to be nearly deserted.

"The sirocco generally continues so short a time in Sicily, that it seldom produces those complaints which are the consequence of its scourching heats in several parts of Italy, though its effects in those countries is much inferior to what is felt in this island. Here it seldom endures longer than thirty-six or forty hours; a time not sufficient to heat the ground, or the walls of the houses, in a very intense continued degree. It is commonly succeeded by the tramontane, or north wind, which in a short time restores the exhausted powers of animal and vegetable life, and nature soon assumes her former appearance. The calamities of this wind have been frequently attempted to be explained, but the different hypotheses are perhaps more to be admired for their ingenuity and fancy than for being very satisfactorily explained. The superior intenseness of this scourching wind at Palermo, may perhaps be accounted for from the situation of that city, which is almost surrounded by hills, the ravines and valleys of which are parched and almost burnt up in summer. The numberless springs of warm water must also greatly increase the intensity of the air; and the practice of burning boughs and heaths on the neighbouring mountains, during the warm season, must undoubtedly tend to increase the heat of the wind in passing over the country of Sicily, though it had previously been disarmed of one of the principal causes of its intensity over the sea which divides Sicily from Africa."

Whether the fatal effects of the sirocco depend entirely upon the degree of fever which is produced by the extreme heat which accompanies it, or whether it is really charged with any quantity of mephitic gas, we have never been sufficiently informed; but wish that any intelligent traveller would examine the state of the air by the eudiometer, and by other tests, during the prevalence of this wind. Should it be found laden with carbo-nic acid, its effects are obviated by suspending in the different apartments, cloths dipped in lime-water; but from the present state of the evidence we are disposed to think that all its evil consequences depend upon a sudden increase of the temperature only.

An extraordinary blasting wind is felt occasionally at Falkland's islands. Happily its duration is short; it seldom continues above twenty-four hours. It cuts the herbage down as if fires had been made under them; the leaves are parched up, and crumble into dust. Fowls are seized with cramps so as never to recover. Men are oppressed with a stopped perspiration, heaviness at the breast, and sore throat; but usually recover with care.

This account is extracted from the travels of Mr. Ives over land to the East Indies. Its fatal effects, if the statement is perfectly correct, evidently proceed from a certain portion of extremely putrid air, which is thus conveyed to us, and we suspect it only happens when a strong wind chance to blow over some very putrid and stagnant lake which is not far distant; travellers, however, are on such occasions commonly in a state of too much alarm to note circumstances with accuracy, and too much of their accounts is collected upon hearsay evidence. This wind, after all, may only consist of a mephitic vapour which destroys life when inhaled, and the putridity which is said so rapidly to take place, may depend more upon the climate than the nature of the wind.

SISON, bastard stone-parsley: a genus of plants belonging to the class of pentadactyla, and to the order of digynia; and in the natural system arranged under the 43th order, umbellata. The root is egg-shaped and streaked; the involucre are subtrichyphyllous. The annulus, inaudatum, segetum, calamum, and annim. The three first are natives of Great Britain. 1. The annamom, common bastard parsley, or field stone-wort, is a biennal herb, of the white, yellow, or red, growing wild in many places of Britain. Its leaves are small, striated, of an oval figure and brown colour. Their taste is warm and aromatic. Their
whole flavour is extracted by spirit of wine, which elevates very little of it in distillation; and hence the spirituous extract has the flavour in great perfection, while the watery extract has a fainter smell and a less agreeable taste. A mixture of the two extracts with pure spirit is of a green colour. The seeds have been esteemed aperient, diuretic, and carminative; but are little regarded in the present practice. 2. The mandarin, head工资watersuit; it grows in ditches and ponds. 3. Segetum, corn parsley or honeywort: it grows in corn-fields and hedges.

SISYMMHRIUM, water-cresses, a genus of plants belonging to the class of tetradaephyra, and to the order of siliquea, and in the natural system ranged under the 39th order, siliquea. The siliqua, or pod, opens with valves somewhat straight. The calyx and corolla are expanded. There are fifty-three species, of which eight are natives of Britain: the nasturtium, common water-cress; sylvestre, water-rocket; amphiabium, water-radarish; terestrius, annual water-radarish; mosneuse, sophia, filxweed; iris, broad-leaved water-cress, and so forth.

SISYRRICHUS, a genus of plants belonging to the class of monadphilia, and order of triandria; and in the natural system ranked under the 6th order, ensato. The spatha is displayed on the petals. The capsule is trilocular and inferior. There are ten species, natives of North America and the Cape.

SITTA, nut-hatch, a genus belonging to the class of aveae, and order of paseriformes: thus characterized by Dr. Latham: The bill is for the most part straight; on the lower mandible there is a small angle; nostrils small, covered with bristles reflected over them; tongue short, horny at the end, and jagged; toes placed three forward and one backward, the middle toe joined closely at the base to both the outmost; tail as long as the middle one. There are fourteen species: the europea, camadensis, carolinensis, jamaicensis, pallasia, major, majorix, siliqua, purpurea, castanea, cajrta, longisora, and chloris. The europea, or nut-hatch, is in length near five inches three-quarters, in breadth nine inches, the bill is strong and very straight, about three inches long; the crown of the head, back, and coverts of the wings, of a fine bluish grey; a black stroke passes over the eye from the mouth; the cheeks and chin are white; the belly is warm orange-colour. The female is like the male, but less in size, and weighs commonly five or at most six drams. The eggs are six or seven in number, of a dirty white, dotted with russet: these are deposited in some hole of a tree, frequently one which has been deserted by a woodpecker, on the rotted wood mixed with a little moss, &c. If the entrance is too large, the bird nicely stops up part of it with clay, leaving only a small hole for itself to pass in and out by. While the hen is sitting, if any one puts a bit of stick into the hole, she hisses like a snake, and is so attached to her eggs, that she will sooner suffer any one to pluck off her feathers than fly away. During the first part of incubation, the male supplies her with sustenance.

The bird runs up and down the bodies of trees, like the woodpecker tribe; and feeds not only on insects, but all kinds of roots, in which it lays up a considerable provision in the hollows of trees. Dr. Plott tells us, that this bird, by putting its bill into a crack in the bough of a tree, can make such a violent sound as it was rending asunder, so that the noise may be heard at a distance of twenty yards.

SIUM, water parsnip, a genus of plants belonging to the class of peptandria, and order of digynium, and in the natural system ranging under the 43rd order, umbellifera. The fruit is a little broader than streaked. The involucrum is polyphyllous, and the petals are heart-shaped. There are nineteen species; three are natives of Britain: 1. The latifolium, or great water parsnip, which grows spontaneously in many places both of England and Scotland, on the sides of lakes, ponds, and rivulets. Cattle are said to have run mad by feeding upon this plant. 2. The angustifolium, or narrow-leaved water-parsnip, grows in ditches and rivulets, but is not common. 3. The nodilorum, reclining water-parsnip, grows on the sides of rivulets.

The sium siciurn, or skirret, is a native of China, but has been for a long time cultivated in Europe, and particularly in Germany. The plant is densely foliaceous; each of which is about as thick as a finger, but very uneven, covered with a whitish rough bark, and has a hard core or pit running through the centre. Skirrets come to maturity at any of the excellent roots, both for flavour and nutritive qualities. They are rather sweeter than the parsnip, and therefore to some few palates are not altogether so agreeable. Mr. Margraf extracted from half a pound of skirret-root an ounce and a half of pure sugar.

SIXTH, in music, an interval formed of six sounds, or five diatonic degrees. There are four kinds of sixths, two consonant and two dissonant. The consonant sixths, are first, the minor sixth, composed of three tones and two semitones major. Secondly, the major sixth, composed of four tones and a major semitone. The dissonant sixths are, first the diminished sixth, composed of two tones and three major semitones. Secondly, the superlunis, composed of four tones, a major semitone, and a minor semitone.

SIZE, the name of an instrument used to find the likeness of fine round pearls. It consists of a thin plate of about two inches long and half an inch broad, fastened together at one end by a rivet. In each of these are round holes drilled of different diameters. Those in the first leaf serve for measuring pearls from half a grain to seven grains; those of the second, for pearls from eight grains or two carats, to five carats, &c.; and those of the third, for pearls from six carats and a half to eight carats and a half.

SKELETON. See Anatomy.

SKELETON. See Anatomy.

SKIMMIA, a genus of the monocotyledon order, in the tetradria class of plants, and in the natural method ranking under the 40th order, verbenaceae. The calyx is quadrangular; the corolla consists of four concave petals; and the berry contains four seeds. There is only one species, viz. the japonica.

SKIN, See Cutis.

SKINNER, one who works in skins. Skinner's work is very delicate, and shall retain any journeyman, &c. to work in their trade, except they themselves have served seven years as apprentices thereto, on pain of for-
stone, earth, &c. serving to retain and raise the water of the sea, a river, &c. and on occasion to let it pass; such is the sluice of a mill, that conducts the water of a rivulet, &c. in order to discharge it at length, in greater plenty, upon the mill-wheel; such are those used in drains, to discharge water of lands; and such are the sluices of Flinders, &c. which serve to prevent the waters of the sea overflowing the lower lands, except when there is occasion to drain them. See Canal.

Construction of sluices. The construction of sluices ought to be conducted by an able engineer, who is well acquainted with the action of fluids in general; and particularly with the situation of the place, the nature of the soil, &c., where the sluice is to be erected; if on the seashore, he ought to be perfectly well acquainted with the effects of the sea on that coast, and the seasons when it is calm or stormy, that he may be able to prevent the fatal accidents thence arising; and if it be a river, it is necessary to know whether it usually overflows its banks, and at what seasons of the year its waters are highest and lowest. The machines for driving the piles should be placed about forty yards from the sides of the sluices, above and below. As to the depth of sluice, it must be regulated by the uses for which they are designed; thus, if a sluice is to be erected at the entrance of a basin for shipping, its depth must correspond with the draught of water of the largest ship that may, at any time, have occasion to enter by it. The rule usually observed, is to make the surface of the bottom of the canal on a level with the low-water mark; but if the bottom of the harbours or canal is such as to be capable of becoming deeper by the action of the water, Belidor very justly observes, that the bottom of the sluice-work should be made deeper than either.

When a sluice is to be placed at the bottom of a harbour, in order to wash away the fill which may gather in it, by means of the waters of a river or canal; in this case the bottom of the sluice-work should be two feet or eighteen inches higher than the bottom of the harbour, that the water may run with the greater violence.

An engineer ought always to have in his view, that the faults committed in the construction of sluices are almost always irreparable. We shall therefore lay down some rules, from Belidor, for avoiding any of these kinds: 1. In order to adjust the level of the sluice-work with the utmost exactness, the engineer ought to determine how much the water must be than a fixed point; and he should mark down in his draught, in the most precise terms possible. 2. When the proper depth is settled, the foundation is next to be examined; and here the engineer cannot be too cautious, lest the apparent goodness of the soil deceive him; if the foundation is judged bad, or insufficient to bear the superstructure, it must be secured by driving piles, or a grate-work of carpentry. 3. There should be engineers enough provided for draining the water; and these should be entirely under the direction of the engineer, who is to take care that they are so placed as not to be an obstacle to the work; and also that the trenches be cut, to convey the water clear from the foundation. 4. When the sluice is to be built in a place where the workmen will be maximally incommoded by the waters of the sea, &c. all the stones for the sluice-work, as well as the timber for that of carpentry, must be prepared beforehand; so that when a proper season offers for beginning the work, there remains nothing to be done, but to fix every thing in its place.

Sluices are made different ways, according to the use they are intended for; when they serve for navigation, they are shut with two gates, presenting an angle towards the stream; but when made near the sea, there are two pair of gates, one to keep the water out, and the other to keep it in, as occasion requires; the pair of gates next the sea present an angle that way, and the other pair the contrary way; the space inclosed by these gates is called a chamber.

When sluices are designed to detain the water in some parts of the ditch of a fortress, they are made with shutters to slide up and down in grooves; and when there are made to cause an inundation, they are shut by means of square timbers let down into culverts, as to lie close and firm.

SMAL'T, a fine glaze, of a dark-blue colour, which, when-levedaged, appears of a most beautiful colour; and if it could be made sufficiently fine, would be an excellent succedaneum for ultramarine, as not only resisting all kinds of weather, but even the most violent fires. It is prepared by melting one part of oxide of cobalt with two of flint-powder, and one of potas. At the bottoms of the crucibles in which the smelting is conducted, we generally find a regulus of a whitish colour inclining to red, and extremely brittle. This is melted afresh, and when cold, separates into two parts; that at the bottom is the cobaltic regulus, which is employed to make more of the small; the other is linament.

SMARAGDITE, in mineralogy. This stone was called smaragdite by M. Sanssure, from some resemblance which it has to the emerald. Neverfigh, we generally find a regulus of a whitish colour inclining to red, and extremely brittle. This is melted afresh, and when cold, separates into two parts; that at the bottom is the cobaltic regulus, which is employed to provide the small; the other is linament.

SMELT, See Salm. See Smelting, in metallurgy, the fusion or melting of the ores of metals, in order to separate the metallic part from the earthy, stony, or other parts. See Smelting, or the art of fusing the ores after roasting, is the principal and most important of metallic operations, all the other being preliminary or preparative to this. The whole attention of the art is directed towards this process; to this all his efforts are applied, because it affords the truly useful product to which his hopes are directed. Though it consists in general in fusing the roasted ore to extract the metal, and in this point of view it seems to present a simple and unvaried operation, in practice, it is by no means the case; many operations are required to bring the metal to its full perfection; and in this sense, Smelting is a science.

SMILAX, rough bindweed, a genus of plants belonging to the class of dicot and order of hexandria; and in the natural system ranging under the 11th order, ranunculacea. The male calyx is hexaphyllous, and there is no corolla; the female calyx is also hexaphyllous, without any corolla; there are three styles, a trilocular berry, and two seeds.

SMILAX, rough bindweed, a genus of plants belonging to the class of dicot and order of hexandria; and in the natural system ranging under the 11th order, ranunculacea. The male calyx is hexaphyllous, and there is no corolla; the female calyx is also hexaphyllous, without any corolla; there are three styles, a trilocular berry, and two seeds.

SMILAX, rough bindweed, a genus of plants belonging to the class of dicot and order of hexandria; and in the natural system ranging under the 11th order, ranunculacea. The male calyx is hexaphyllous, and there is no corolla; the female calyx is also hexaphyllous, without any corolla; there are three styles, a trilocular berry, and two seeds. There are 22 species; of these, the smilax saraparilla, which affords the sarsaparilla root, is the most valuable. This is well described in the London Medical Journal by Dr. Wright, who, during a long residence in Jamaica, made botany his peculiar study.

"This species (says he) has stems of the thickness of a man's finger: they are jointed, jointed, and hooked spines. The leaves are alternate, smooth and shining on the upper side: on the other side are three nerves or costae, with sordid small crooked spines. The flower is yellow, mixed with red. The fruit is a black berry, containing several brown seeds."

SARSAPARILLA, in medicine, a species of herb, the root of which is considered as a tonic, and is employed for the treatment of certain diseases.

road, has roundish, prickly-stalked and red berries, and is a native of China and Japan. The pseudo-china, or occidental species, has rounder smooth stalks, and black berries, grows wild in Jamaica and Virginia, and bear the costly of our own climate. At present the China root is very rarely made use of, having for some time given place to sarsaparilla, which is more efficacious and thrifty. Prosper Alpinus informs us, that this root is in great esteem among the Egyptian women for procuring fitness and plumpness.

Smithery, or Smithing, a manual art, by which an artificial lump of iron is wrought into an intended shape.

Smitha, a genus of the decandra order, in the diadelphus class of plants; and in the natural method ranking under the 32d order, papilionaceae. The calyx is many, yellow and bilatrated; the corolla winged; the stamens in number, with three or four joints, and containing as many seeds, which are smooth, compressed, and kidney-shaped. There is only one species, viz. the sepiaria, an annual one of North America.

Smoke-jack. See Jack.

Smut. See Husbanry.

Smyth. See Sugdeny.

Snowdrop. The snowdrop is a genus of plants belonging to the class of peonia, and to the order of digyza; and in the natural system ranging under the 4th order, umbellifera. The fruit is oblong and striated; the petals having a sharp point, and are keel-shaped. There are seven species: 1 The perfoliatum, or perfoliate alexanders, which is a native of Candia and Italy; 2. The Erythraenum; 3. The aurum, or golden alexanders, which is a native of North America; 4. The integerrimum; 5. The oclusum, common alexanders, a native of Britain; 6. The leaves of which are curule, ternet, petiolated, and serrated. It grows on the shore of the Channel, and in Devonshire, North Britain. Since the introduction of celery into the garden, the alexanders is almost forgotten. It was formerly cultivated for salading, and the young shoots or stalks blanched were eaten either raw or stewed. The leaves were also used in broths and soups. It is a warm comfortable plant to a cold weak stomach, and was in much esteem among the monks, as may be inferred by its still being found in great plenty by old abbeys, &c. Laterate. 7. Aphrodite.

Snowdrop. See Galanthus.

Snowdrop-tree. See Chionanthus.

Snowy. A powder chiefly made of tobacco, the use of which is too well known to need any description here. See Nicotiana.

Snapdragon, in botany. See Antirrhinum.

Soap. The fixed oils have the property of combining with alkalis, earths, and metatellite, to form soaps; and this is a class of compounds which have received the name of soaps. As these soaps differ from each other very materially, according as their base is an alkali, an earth, or an oxide, it will be proper to consider each set separately.

Soaps, alkaline. As there are a great number of fixed oils, all or most of which are capable of combining with alkalis, earths, or oxides, it is natural to suppose that there are as many genera of alkaline soaps as there are oils. That there are differences in the nature of soaps corresponding to the oil which enters into their composition, is certainly true; but these differences are not of sufficient importance to require a particular description. It will be sufficient, therefore, to divide the alkaline soaps into as many species as there are alkalis, and to consider those soaps which have the same alkali base, but must in their oil, as varieties of the same species.

Soap of soda, or hard soap. The word soap (sapon.) first occurs in the works of Pliny and Galen, and is evidently derived from the old German word, sepe. Pliny informs us that soap was first discovered by the Gauls; that it was composed of tallow and ashes; and that the German soap was reckoned the best.

Soap may be prepared by the following process: a quantity of the soaps of commerce, if pounded, and mixed in a wooden vessel, with about a fifth part of its weight of lime, which has been slaked and passed through a sieve immediately before. Upon this mixture is a quantity of water is poured, considerably more than is sufficient to cover it, and allowed to remain on it for several hours. The lime attracts the carbonic acid from the soaps, and the water becomes strongly impregnated with the pure alkali, which is, in that manner, at once precipitated in the form of lime, and at the same time, the soap is drawn off by means of a stop-cock, and called the first ley. Its specific gravity should be about 1.200.

Another quantity of water is then to be poured on the soaps, which, after standing two or three days, is worn to sediment. Off by means of the stop-cock, and called the second ley.

Another portion of water is poured on; and after standing a sufficient time, is drawn off like the other two, and called the third ley. This water is still more sedentary, and is to be poured on, in order to be certain that the whole of the soaps is dissolved; and this weak ley may be put aside, and employed afterwards in forming the first ley in subsequent operations.

A quantity of oil, equal to six times the weight of the soaps used, is then to be put into the boiler, together with a portion of the third or weakest ley; and the mixture must be kept boiling and agitated constantly, by means of a wooden instrument. The whole of the third ley is to be added at intervals to the mixture; and after it is consumed, the second ley must be added in the same manner. The oil becomes milky, combines with the alkali, and after some hours it begins to acquire consistence. A little of the first ley is then to be added, not forgetting to agitate the mixture constantly. Portions of the first ley are to be added at intervals; the soap substance acquires greater consistence, and at last it begins to separate from the watery part of the mixture. A quantity of common salt is then to be added, which renders the separation much more complete. The boiling is to be continued still for two hours, and then the first ley is to be withdrawn, and the liquor must be no longer agitated. After some hours reposes, the soap separates completely from the water, and swells upon the surface of the liquor. The watery part is then to be drawn off; and as it contains a quantity of carbonat of soda, it ought to be reserved for future use.

The fire is then to be kindled again; and, in order to facilitate the melting of the soap, a little water, or rather weak ley, is to be added to it. As soon as it boils, the remainder of the first ley is to be added to it at intervals. When the soap has been brought to the proper consistence, which is judged by taking out small portions of it and allowing it to cool, it is to be withdrawn from the fire, and the watery part separated from it as before. It is then to be heated again, and a little water mixed with it, that it may form a proper paste. After this let it be poured into the vessels proper for cooling it; in the bottom of which there ought to be a little chalk in powder, to prevent the soap from adhering. In a few days, the soap will acquire sufficient consistence to be taken out, and formed into proper cakes.

The use of the common salt in the above process, is to separate the water from the soap; for common salt has a stronger affinity for water than soap has.

Olive-oil has been found to answer best for making soap, and next to it perhaps tallow may be used; but a great variety of other oils may be employed for that purpose, as appertains from the experiments of the French chemists. They found, however, that linseed-oil and whale-oil were not proper for making hard soaps, though they might be employed with advantage in the manufacture of soft soaps. Whale-oil has been long used by the Dutch for this last purpose. Soap may also be made without the assistance of heat; but in that case a much longer time and a larger proportion of alkali are necessary.

Manufacturers have contrived various methods of sophisticating soap, or of adding ingredients which increase its weight without increasing its value. The most common substance used for this purpose, which may be added in considerable quantities, especially to soap made with tallow (the ingredient used in this country), without diminishing its consistence. This fraud cannot be readily detected, or the bait so placed as to lie for some time exposed to the air. The water will evaporate from it, and its quantity will be discovered by the diminution of the weight of the soap. As soap sophisticated in this manner would lose its water by being kept, manufacturers, in order to prevent this, keep their soap in saturated solutions of common salt; which do not dissolve the soap, and at the same time, by preventing all evaporation, preserve, or rather increase, the weight of the soaps. Darcet, Lejeune, and Pelletier, took two pieces equal in weight of soap sophisticated in this manner, and placed the one in a dry place in the open air, and the other in a saturated solution of common salt; after a month the latter had lost 0.36 of its weight, the other had gained about 0.10 parts. Various other methods have been fallen upon to sophisticate soap; but as they are not generally known, it would be doing an injustice to the public to describe them here.

Different chemists have analysed soap, in
Soap is soluble both in water and in alcohol. Its properties as a detergent are too well known to require any description.Soap made with tallow and soda has a white colour, and is therefore known by the name of white soap; but it is usual for soapmakers, in order to lower the price of the article, to mix a considerable portion of resin with the tallow; this mixture forms the common yellow or turpentine soap of this country.

Soap of potash, or soft soap. Potash may be substituted for soda in making soap, and in that case precisely the same process is to be followed. It is remarkable, that when potash is used, the soap does not assume a soapy smell. Its consistence is never greater than that of hog's lard. This is what in this country is called soft soap. Its properties as a detergent do not differ materially from those of hard soap, but it is not so convenient for use. The alkali employed by the ancient Greeks and Romans in the formation of soap was potash; hence we see the reason that it is described by the Romans as an unguent. The oil employed for making soft soap in this country is white-oil. A little tallow is also added, which, by peculiar management, is dispersed through the soap in fine white spots.

Some persons have affirmed that they knew a method of making hard soap with potash. Their method is this: After forming the soap in the manner now described, they add to it a large quantity of common salt, boil it for some time, and the soap becomes solid when cooled in the usual way. That this method may be practised with success, has been declared by Messrs. Darcey, Lelievre, and Pelletier; but then the hard soap thus formed does not contain potash but soda; for when the common salt (muriate of soda) is added, the potash of the soap decomposes it, and combines with its muriatic acid, while at the same time the soda of the salt combines with the oil, and forms hard soap; and the muriate of potash formed by this double decomposition is dissolved in water, and drawn off along with it.

Chapital has lately proposed to substitute wool in place of oil in the making of soap. The ley is formed in the usual manner, and made boiling hot, and shreds of wooden chopp of any kind are gradually thrown into it; they are soon dissolved. New portions are to be added sparingly, and the mixture is to be constantly agitated. When no more cloth can be dissolved, the soap is made. This soap is said to have been tried with success. It might doubtless be substituted for soap with advantage in several manufactures provided it can be obtained at a cheaper rate than the soap at present employed.

Some time ago a proposal was made to substitute the muscles of fish instead of tallow or oil for common soap; but the experiments of Mr. Jamieson have demonstrated that they do not answer the purpose.

**Soap of ammonia.** This soap was first particularly attended to by Mr. Berthollet. It may be made by dissolving carbonate of ammonia on soap of lime. A double decomposition takes place, and the soap of ammonia swins upon the surface of the liquor in the form of an oil; or it may be formed with still greater ease by pouring a solution of muriat of ammonia into common soap dissolved in water.

It has a more pungent taste than common soap. Water dissolves a very small quantity of it; but it is easily dissolved in alcohol. When exposed to the air, it is gradually decomposed. The substance called volatile emulsion, which is employed as an external application in rheumatism, colds, &c. may be considered as scarcely any thing else than this soap.

All the alkaline soaps agree in the properties of solubility in water and alcohol, and in being powerful detergents.

Soaps, early. The earthy soaps differ essentially from the alkaline in their properties. They are insoluble in water, and incapable of being employed as detergents. They may be formed very readily by mixing an earthy substance with a solution of an earthy salt. The alkali of the soap combines with the acid of the salt, while the earth and oil unite together and form an earthy soap. Hence the reason that all waters holding an earthy salt are unfit for washing. They decompose common soap, and form an earthy soap insoluble in water. These waters are well known by the name of hard waters. Hence the early soaps have been examined by Mr. Berthollet only.

**Soap of lime.** This soap may be formed by pouring lime-water into a solution of common soap. It is insoluble both in water and alcohol. Carbonat of fixed alkali decomposes it by its solubility. It melts with difficulty, and requires a strong heat.

**Soap of barytes and of strontium resemble almost exactly the soap of lime.**

**Soap of magnesia may be formed by mixing together the solutions of common soap and sulphat of magnesia.** It is exceedingly white. It is unctuous, dries with difficulty, and preserves its whiteness after desiccation. It is insoluble in boiling water. Alcohol and fixed oil dissolve it in considerable quantity. Water renders its solution in alcohol milky. A moderate heat melts it; a transparent mass is formed, slightly yellow, and very brittle.

**Soap of alumina may be formed by mixing together the solutions of alum and of common soap.** It is a flexible soft substance, which retains its suppleness and tenacity when dry. It is insoluble in alcohol, water, and oil. Heat easily melts it, and reduces it to a beautiful transparent yellowish mass.

**Metallic soaps** are formed by combining with oils by two different processes: 1. By mixing together a solution of common soap with a metallic salt. 2. By uniting the metallic oxide with the oil directly, either cold or hot. The first of these combinations is called a metallic soap; the second a plaster. See PLASTER.

**SOAPS, metallic.** These soaps have been examined by Mr. Berthollet; who has proposed some of them as paints, and others as varnishes; but it does not appear that any of them has been hitherto applied to these purposes.

1. Soap of mercury may be formed by mixing together a solution of common soap and corrosive muriat of mercury. The liquor becomes milky, and the soap of mercury is gradually precipitated. This soap is viscid, not easily dried, loses its white colour when exposed to the air, and acquires a slate-colour, which gradually becomes deeper, especially if exposed to the sun or to heat. It dissolves very well in oil, but sparingly in alcohol. It readily becomes soft and fluid when heated.

2. Soap of zinc may be formed by mixing together a solution of sulphat of zinc and of soap. It is of a white colour, inclining to yellow. It dries quickly, and becomes inible.

3. Soap of cobalt, made by mixing nitrat of cobalt and common soap, is of a dull leaden colour, and dries with difficulty, though its parts are not conducted.

Mr. Berthollet observed, that towards the end of the precipitation there fell down some green muriat of copper consistent than soap of cobalt. These he supposed to be a soap of nickel, which is generally mixed with cobalt.

4. Soap of tin may be formed by mixing common soap with a solution of tin in nitric acid. It is white. Heat does not fuse it like other metallic soaps, but decomposes it.

5. Soap of iron may be formed by means of sulphat of iron. It is a reddish-brown colour, tenacious, and easily fusible. When spread upon wool, it sinks in and dries. It is easily soluble in oil, especially of turpentine. Berthollet proposes it as a varnish.

6. Soap of copper may be formed by means of sulphat of copper. It is of a green colour, has the feel of a resin, and becomes dry and brittle. Hot alcohol renders its colour deeper, but scarcely dissolves it. Ether dissolves it, and renders its colour deeper and more beautiful. It is very soluble in oils, and gives them a pleasant green colour.

7. Soap of lead may be formed by means of acetite of lead. It is white, tenacious, and very adhesive when heated. When fused it is transparent, and becomes somewhat yellow if the heat is increased.

8. Soap of silver may be formed by means of nitrat of silver. It is at first white, but becomes reddish by exposure to the air. When fused, its surface becomes covered with a brilliant iris; beneath the surface it is black.

9. Soap of gold is formed by means of muriat of gold. It is at first white, and of the consistence of cream. It gradually assumes a dirty purple colour, and adheres to the skin.

10. Soap of manganese is formed of sulphat of manganese. It is at first white, and then by absorbing oxygen it becomes red.

**SOCAGE,** an ancient tenure, by which lands were held on condition of ploughing the lord’s lands, and doing the operations of husbandry, at their own charges.

**SOCCUS,** a kind of high shoe, reaching above the ankle, worn by...
SODA, or SOFFIT, in architecture, any platurn or ceiling formed of cross beams of flying cornices, the square compartments or panels of which are enriched with sculpture, painting, or gilding.

SOIL, or SOD, a French coin made up of copper mixed with a little silver, value the 25th part of our shilling.

SOL, or SOL, in music, the fifth note of the gamut, ut, re, mi, fa, sol. See Gamut.

SOL, or SOIL, See HUSBANDY.

SOIT fàit comme il est désiré, be in done as it is desired, a form used when the king gives the royal assent to a private bill preferred in parliament.

SOL, in music, the fifth note of the gamut, ut, re, mi, fa, sol. See Gamut.

SOL, or SOIL, in the old chemistry, is gold.

SOLON, a genus of plants belonging to the class of pentandria, and to the order monogynia. The calyx is bursting; the corolla elevate, tube-formed, very large; berries are round, and the species is grandiflora. This genus was first named solandra in honour of Dr. Solander, by Murray, in the 14th edition of the Systema Vegetabilium. In Jamaica it is called the peach-coloured trumpet-flower.

SOLANUM, a genus of the monogynia order, in the pentandria class of plants, and in the natural method ranking under the 28th order, lurida. The calyx is inferior; the corolla is rotund and monopetalous; the fruit a berry; and the seeds are small and flat seeds. Of this genus there are 93 species, most of them natives of the East and West Indies, the most remarkable of which are the following:

1. The dulcamora, woody nightshade a native of Britain and of Africa, is a slender climbing plant, rising to six or more feet in height. The leaves are generally oval, pointed, and of a deep-green colour; the flowers are small and white, and divided into five pointed segments. The calyx is plicate, persistent, and divided into five; the berry, when ripe, is red, and contains many flat yellowish seeds. It grows in hedges well supplied with water, and flowers about the end of June. On pouring the roots, we first feel a bitter, then a sweet taste: hence the name. The berries are said to be poisonous, and may easily be mistaken by children for currants. For young branches are directed for use, and may be employed either fresh or dried; they should be gathered in the autumn. This plant is generally given in decoction or infusion. Several authors take notice, that the dulcamara portentous of the malicious powers of the nightshade, joined to a cold and aconiacous quality; hence it promotes the secretions of urine, sweat, the menses, and lochia; also in some obstinate cutaneous diseases.

2. The nigron, garden nightshade, common in many places in Britain about houses, and in waste places.

3. In height. The stalk herbaceous; the leaves alternate, irregularly oval, indented, and clothed with soft hairs. The flowers are white; the berries black and shining. It appears to possess the seeds of the other nightshades in a very high degree, and even the smell of the plant is said to cause sleep. The berries are equally poisonous with the leaves, causing cardiaque and delirium, and violent distortions of the limbs in children. Mr. Getaker, in 1757, recommended its internal use in old sores, in scorbutic and cancerous ulcers, cutaneous eruptions, and in dropsy. He says, that one grain of this seed, in an ounce of water, sometimes produced a considerable effect; that in the dose of two or three grains it seldom failed to evacuate the first passages, to increase very sensibly the di-charges by the skin and kidneys, and sometimes to occasion head-ache, drowsiness, giddiness, and diarhœa of sight. Mr. Brompton declares, that in cases in which he tried the solanum they were much aggravated by it; and that in one case they were entirely fatal to one of his patients; therefore he contends its use is prejudicial. This opinion seems tacitly to be confirmed, as it is now never given internally. In ancient times it was employed externally, to anoint, and anodyne in some cutaneous affections, tumefactions of the glands, ulcers, and disorders of the eyes. The solanum nigron rubrum, a native of the West Indies, is called ganna by the negroes. It is so far from having any deleterious quality, that it is daily served up at table as greens or spinach. It has an agreeable bitter taste.

4. The lupercum, the love-apple, or tomato, cultivated in gardens in the warmer parts of Europe, and in all tropical countries. The stalk is herbaceous; the leaves pinnated, ovate, pointed, and deeply divided. The flowers are on simple racemes; they are small and yellow. The berry is of the size of a plum; they are smooth, shining, soft; and are either of a yellow or reddish colour. This tomato is in daily use: being either boiled in soups or broths, or served up boiled as garnishes to fish.

5. Melongena, the egg plant, or vegetable egg. This is also cultivated in gardens, particularly in Jamaica. It seldom rises above a foot in height. The fruit is as big as, and contains many flat yellowish seeds. It grows in hedges well supplied with water, and flowers about the end of June. On pouring the roots, we first feel a bitter, then a sweet taste: hence the name. The berries are said to be poisonous, and may easily be mistaken by children for currants. For young branches are directed for use, and may be employed either fresh or dried; they should be gathered in the autumn. This plant is generally given in decoction or infusion. Several authors take notice, that the dulcamara portentous of the malicious powers of the nightshade, joined to a cold and aconiacous quality; hence it promotes the secretions of urine, sweat, the menses, and lochia; also in some obstinate cutaneous diseases.
very like, the egg of a goose. It is often used boiled as a vegetable along with animal food or butter, and supposed to be aphrodisiac and to cure sterility.

5. Longum. This plant is also herbaceous, but grows much ranker than the foregoing. The flowers are blue; and the fruit is six or eight inches long, and proportionally thick. It is boiled and eaten at table as the egg-plant.

6. Tuberosum, the common potato. It was introduced by Sir Walter Raleigh, and first cultivated in Ireland about the year 1600. Cuient forms have been made of the culture of potatoes at Westmian in Essex.

SODANELLA, in botany, a genus of plants of the class of pantennaria, and order of monogyna, and in the natural system arranged under the 21st order, precie. The coccus is campulatus; the border being very finely cut into a great many segments. The capsule is unilocular, and its apex polypetale. There is one species.

SOLDER, SODER, or SODER, a metallic or mineral composition used in soldering or joining other metals. Solders are made of gold, copper, tin, and lead. The composition usually observed, that in the composition there shall be some of the metal that is to be soldered mixed with some higher and finer metals. Goldsmiths usually make four kinds of solder, viz. solder of eight, where to seven parts of silver there is one of brass or copper; solder of six, where only a sixth part is copper; solder of four, and solder of three. It is the mixture of copper in the solder that makes raised plate come always cheaper than flat.

As mixtures of gold with a little copper are found to melt with less heat than pure gold itself; these mixtures serve as solders for gold; two pieces of fine gold are soldered by gold that has a small mixture of copper; and gold alloyed with copper is soldered by such as is alloyed with more copper. The workmen add a little silver as well as copper, or more of the one than of the other, so as to make the colour of the solder correspond as nearly as may be to that of the piece. A mixture of gold and copper is also a solder for fine copper as well as for fine gold. The quantity of copper deposited, or to unite with iron, proves an excellent solder for the finer kinds of iron and steel instruments.

The solder used by plumbers is made of two pounds of lead of one block-in. Its goodness is tried by melting it, and pouring the size of a crown piece on a table; for, if good, there will arise little bright shining stars in it. The solder for copper, is made like that of lead, and copper or tin; and for very nice works, instead of tin, they sometimes use a quantity of silver. Solder for tin is made of two-thirds of tin and one of lead, or of equal parts of each; but where the work is any thing delicate, as in organ-pipes, where the tin, bismuth, and silver are so finely divisible, it is made of one part of bismuth and three parts of pewter. The pewterers use a kind of solder made with two parts of tin and one of bismuth; this composition melts with the least heat of any of the solders.

Silver solder is that which is made of two parts of silver and one of brass, and used in soldering those metals. Spelter solder is made of one part of brass and two of spelter or zinc, and is likewise used for the braziers and other vessels for the heating of iron, or for use of oven, and is also made of zinc and copper. The composition called Bismuth solder is made of one part of bismuth, and three of tin; this is used in soldering pewter, brass, and brassed objects.

SOLUCES, among the Romans, a kind of sandals or slippers which covered only the sole of the feet, and were bound on with thongs of leather, instead of which the women and the eminential ones of the other sex tied them on with purple-coloured ribbons, or such as were variously adored with gold and silver.

SOLECISM, soloezicus, in grammar, a false manner of speaking contrary to the use of language and the rules of grammar, either in respect of declension, conjugation, or syntax.

SOLEN, sector sheath, or knife-handle sheath, a genus belonging to the class of vermes, and order of testacea. The animal is an ascidian. The shell is oblong, and opening at both sides; the hinge has a tooth shaped like an awl, bent back, often double, not inserted into the opposite shell; the rim at the sides somewhat worn away, and has a prominence without. There are 23 species; three of them, viz. the silicus, vagina, and esius, are found on the British coasts, and lurk in the sand near the low-water mark in a peculiar direction. When in want of food, they elevate one end a little above the surface, and protrude their bodies far out of the shell. On the approach of danger they dart deep into the sand, sometimes two feet at least. Their place is known by a small dimple on the surface. Sometimes they are dug out of the sand; at other times they are taken by striking a barbed dart suddenly into them. When the sea is down, these fish usually run deep into the sand, and to bring them up, the common custom is to throw them into the holes, on which the fish raises itself, and in a few minutes appears at the mouth of its hole.

When half the shell is discovered, the fisherman has nothing more to do than to take hold of it with his finger, and draw it out; but he must be cautious not to lose the occasion, for the creature does not continue a moment in that state; and if by any means the fisherman has touched it, and let it slip away, it is gone forever; for it will not be decoyed again out of its hole by salt; so that there is then no way of getting it but by digging under it, and throwing it up with the sand. The fish has two pipes, each composed of four or five rings or portions of a hollow cylinder, of unequal lengths, joined one to another; and the places where they join are marked by a number of fine streaks.

The reason why the salt causes these creatures to come out of their holes, is, that it gives them violent vitality, and even corrodes these pipes. This is somewhat strange, as the creature is nourished by means of salt water; but it is very evident, that if a little salt is spread upon these pipes in a fish taken out of its habitations, it will corrode the joinings of the rings, and often make one or more joints drop off; the creature, to avoid this mischief, arises out of its hole, and throws off the sand, and then retires back again. The use of these pipes to the animal is the same with that of many other pipes of a like kind in other shell-fish; they all serve to take in water; they are only a continuation of the outer membrane of the fish, and serve indifferently for a sinuous and throwing out the water, one receiving and the other discharging it, and either answering equally well to their purpose.

This fish was used as food by the antiques; and Athenaeus, flor. Sophron, speaks of it as a great delicacy, and particularly grateful to widows. It is often used as food at present, and is brought up to table fried in eggs.

SOLING, or SOLISATION, the art of sounding the note, together with the corresponding syllables of the gamut. This
SOL preparatory exercise, so necessary to sight-singing, and which, by uniting in the mind of the practitioner the ideas of the different syllables with those of the intervals, facilitates the recollection of the several sounds, was of very antient adoption.

Guido having substituted his hexachord in place of the tetradchord, adopted at the same time for his solmization six other syllables, ut, re, mi, fa, sol, la, taken from the hymn of St. John the Baptist.

Of the seven notes in the French scale, only four are used, as ut, re, fa, sol, la; but now we, as well as the Italians, employ the first six, with the exception of shaking ut for do, as a softer and more vocal syllable. By applying these syllables to the several notes, the practitioner not only utters the sound with more fulness, ease, and freedom, but, by the association of ideas, attains a ready recollection of the places of the tones and semitones, and by feeling the relation between the syllabic and the musical sounds, acquires the power of expressing them with truth and certainty.

SOLICITOR, a person employed to take care of, and manage, suits depending in the courts of equity, and those of the lower sort, with the advice of the damage of the people, and the increase of chancery and maintenance.

Solicitors are within the statute to be sworn and admitted by the judges, before they are allowed to practise in our courts, in like manner as attorneys.

SOLID. Geometrarians define a solid to be the third species of magnitude, or that which has three dimensions, viz. length, breadth, and thickness or depth.

A solid may be conceived to be formed by the revolution, or direct motion, of a superficies of any figure whatever, and is always terminated or contained under one or more planes or surfaces, as a surface is under one or more lines.

Solids are commonly divided into regular and irregular. The regular solids are those terminated by regular and equal planes, and are only the figures of the better sort, which consists of four equal triangles: the cube, or hexahedron, of six equal squares; the octahedron, of eight equal triangles; the dodecahedron, of twelve; and the icosahedron, of twenty equal triangles. See TETRAHEDRON, CUBE, &c.

SOLID OF LEAST RESISTANCE. Sir Isaac Newton, in his Principia, shews that if there is a curve figure, as DNFG, (Plate Miscell. fig. 218.) of such a nature, that from any point, as N, taken in its circumference, a perpendicular NM is let fall on the axis AB; and if from a given point, as G, there is drawn the right line GR, parallel to a tangent to the curve in the point N, cutting the axis produced, and taking all the proportion then is, as NM:GR::GR:4BG X GR; the solid generated by the revolution of this curve about its axis AB, when moved swiftly in a rare and elastic medium, will meet with less resistance in the medium, than any other circular solid whatever, of the same length and breadth.

SOLID ANGLE, is that formed by three or more planes meeting in a point, like the point of a dice, well cut.

SOLID NUMBERS, are those which arise from the multiplication of a plane number, by any other whatever: as 18 is a solid number made of 6 (which is plane), multiplied by 3; or of 9 multiplied by 2.

SOLID PROBLEM, in mathematics, is one which cannot be geometrically solved unless by the intersection of a circle and a conic section; or by the intersection of two other conic sections. The receptacle is naked; the pappus simple; the radii are commonly five; the scales of the calyx are imbricated, and curved inward. There are 30 species. Among these there is only one which is a native of the virginia, or common golden rod, which grows frequently in rough mountainous pastures and woods. There is a variety of this species called cambria, to be found on rocks, from six inches to a foot high.

SOLIDITY is that property of matter, by which it excludes all other bodies from the place which itself possesses.

SOLITARIES, a denomination of nuns of St. Peter of Alcantara, instituted in 1676, the design of which is to lead a severe religious life, but thus they are to keep a continual silence, never to open their mouths to any body; employ their time wholly in spiritual exercises, and leave the temporal concerns to a number of nuns, who have a particular superiority in a separate part of the monastery; they always go barefooted, without sandals; gird themselves with a thick cord, and wear no linen.

SOLO, in music, a term used in pieces consisting of several parts, to mark those that are to perform alone: it is sometimes denoted by S.

When two or three parts play, or sing, separately from the grand chorus, they are called a duo, trio, or soli.

SOLSTICE. See Astronomy.

SOLUTION, in chemistry, denotes an intimate mixture, or perfect union, of solid bodies with fluids, so as seemingly to form one homogenous liquor. The dissolving fluid is termed the solvent or menstruum. A solution is distinguished from a mixture by being perfectly clear, though not always colourless, and from the parts not separating when set at rest. See CHEMISTRY.

SOLUTION, in algebra and geometry, is the answering a question, or the resolving any problem proposed.

SOLUTION OF CONTINUITY, in surgery, is the separation of the natural cohesion of the solid parts of the body, by a wound.

SONOMET, a mineral named from the mountain Sonnena, where it was first found. It is usually mixed with volcanic productions. It crystallizes in prisms, sometimes terminates by pyramids. Colour white, and somewhat transparent. It cuts glass. The specific gravity is 3.37. Insoluble by the blowpipe: and according to Vaquerin, it is composed of

SONATA, in music, a piece, or composition, intended to be performed by instruments only; in which sense it stands opposed to cantata, or a piece designed for the voice.

There are several kinds of sonatas. The Italians, however, reduce them principally to two: the sonata da camera, or chamber sonata; and the sonata da chiesa, or church sonata. The sonata, of whatever kind, generally opens with an adagio; and after two or three movements of various descriptions, concludes with an allegro, or a presto. This definition of a sonata, however, rather belongs to what is called the antient than to the modern music, in which the sonata is chiefly composed as a lesson or exercise for a single instrument.

SONORMUS, sax-thesis, a genus of plants belonging to the class of syngezenia, and to the order of polynomia epipeps, and in the natural system ranged under the 40th order, composites. The receptacle is naked; the calyx is imbricated, bellish, and conical; the crown of the seed is simple, sessile, and very soft; the seed is oval and pointed. There are 19 species; four of these are natives of Britain: 1. Pulistris, marsh sax-thistle. 2. Arvensis, corn sax-thistle. 3. Geranium, common sax-thistle. 4. Alacantara, rare sax-thistle. All of them noxious weeds.

SONG, in poetry, a little composition, consisting of easy and natural verses, set to a tune in order to be sung. See POETRY.

SONG, in music, is applied in general to a single piece of music, whether contrived for the voice or an instrument.

SONG OF BIRDS, is defined by the honourable Daines Barrington to be a succession of three or more different notes, which are continued without interruption, during the same interval, with a musical bar of four crotchets in an adagio movement, or whilst a penitum swings four seconds. It is affirmed by this authoress that the notes of birds are not more innate than language in man, and that they depend upon imitation, as far as their organs will enable them to imitate the sounds naturally and their adhering so steadily, even in a wild state, to the same song, is owing to the nestlings attending only to the instruction of the parent bird, whilst they disregard the notes of all others that may perhaps be singing round them.

Birds in a wild state do not commonly sing above 10 weeks in the year; whereas birds that have plenty of food in a cage, sing
Mr. Barrington has observed, that in the nightingale, which is a very capital bird, began so like the actions of graters, reserving its breath to swell certain notes, which by these means had a most astonishing effect. This writer adds, that the notes of birds, which are annually imported from Asia, Africa, and America, both singly and in concert, are not to be compared to those of European birds.

The following table, formed by Mr. Barrington, agreeing to the idea of M. de Filis, in which the notes of the most beautiful, is designed to exhibit the comparative merit of the British singing birds; in which 20 is supposed to be the point of absolute perfection.

SONNERTIA, a genus of plants belonging to the class of icossana, and to the order of monogynia. The calyx is cut into six segments; the petals are six; the capsule is multilocular and succulent; and the cells contain many seeds. The only species is the acida, a tree of New Guinea.

SONNET. SEE POETRY.

SOOT, a substance deposited from the flame of combustibles. It consists chiefly of carbon, which, for want of complete contact with the air, could not be consumed, and is partly carried off mechanically with the smoke, and partly precipitated.

SOPHORA, a genus of plants belonging to the decamerr monogynia class, with a papilionaceous flower: its fruit is a very long and slender unilocular pod, containing a great many roundish seeds. It agrees in every thing with the didepida and papilionaceous plants, except that its stamina are distinct and separate. There are 25 species, all foreign shrubs.

SORBUS, service-tree, a genus of plants belonging to the class isossana, and to the order of trigynia. The calyx is quinquelobed; the petals are five; the berry is below the flower, soft, and containing three seeds. There are three species; the aucuparia, domestic, and hebrida.

1. The aucuparia, mountain-ash, quicken-tree, quick-beam, or roso-tree, rises with a straight upright stem and regular branches: resem- bles the blackthorn, as well as in compass and variety, is only second to the nightingale. The nightingale also sings (if the expression may be allowed) with superior judgment and taste, flowers at the sides and ends of the branches, succeeded by clusters of small red berries, ripe in autumn and winter. There is a variety with yellow-striped leaves. This species grows wild in many parts of this island, in mountainous places, woods, and hedge-rows, often going to the size of a small tree, and is admitted into our ornamental plantations, for the beauty of its growth, foliage, flowers, and fruit.

2. The domestia, or cultivated service-tree, with cattail fruit, grows with an upright stem, branching 30 or 40 feet high, or more, having dark bark, and the young shoots in spring covered with a newly down: pinnaed leaves of eight or ten pairs. This tree is a native of the southern warm parts of Europe, where its fruit is used at table as a dessert; it is cultivated here in many of our gardens as a fruit-tree, and as an ornament to diversify hardy plantations.

3. The hebrida, or mongrel service-tree of Gothland, grows 20 or 30 feet high; it has half pinnaed leaves, very downy beneath; and clusters of white flowers, succeeded by bunches of round reddish berries in autumn.

SOROLL, moss-chats, is a genus of quadrupeds of the order tereo. The generic character is, from the upper jaw two, long, bird; in the lower, two or three, the intermediate ones shorter; canine teeth, several on each side; grinders cuspidated.

The genus soroll, of which there are 17 species, in its general appearance bears a great resemblance to the mouse tribe; but the structure, number, and situation of the teeth prove it to constitute a very different set of animals, which are evidently rather carnivorous. It is more closely allied to the genus talpa; though this has two teeth in the upper jaw, the soroll is entirely destitute of teeth connected by each other intermediate species, which in habit resemble the one genus, and in teeth the other. It is owing to this circumstance that Mr. Linnaeus, in the twelfth edition of the Systema Naturae, has given two genuine species of talpa in the genus soroll. The most common species of soroll in this country is the S. aranatus, commonly known by the name of the shrew-mouse.

SOREX ARANUS. This little animal, which is perhaps the smallest of the European quadrupeds, is a very common inhabitant of our fields and gardens, and measures about two inches and a half, and the tail one and a half. Its colour is nearly similar to that of a mouse, but of a somewhat more ferruginous tinge; and the animal is readily distinguished by its long and sharp snout; the eyes are small, and almost hid in the fur. It feeds on roots, grain, insects, and almost any kind of neglected animal substance. It has a very strong and unpleasant smell; and it is remarkable that cats will kill but not eat it. Mr. Pennant observes that there seems to be an annual mortality among these little animals every autumn; numbers of them being found dead at this season by paths and in the fields. It inhabits most parts of Europe, and is also said to be found in Siberia and Kamtschatka. It breeds in March, in the leafless moss, &c., and is said to produce several young at a time.

2. Sorex muschelius, musk-shrew. This is a very singular species, which, though ex-
tremely common in some of the northern parts of Europe and Asia, does not seem to have been very distinctly understood by modern naturalists.

According to Dr. Pallas, it chiefly inhabits the river Wolua and the adjacent lakes, from Novgorod to Saratof; and is not found in Russia, nor does its existence in Lapland seem well ascertained. It is said to be very seldom seen on land; confined itself to lakes and rivers, in the banks of which it occasionally burrows to a great distance. The general length of the animal is about seven inches from nose to tail, and of the tail eight inches; but it is sometimes found of a larger size. The tail, except at its base, is perfectly naked, marked out into scaly divisions, and is of a brown colour; it is also of a laterally compressed form, and gradually tapers to the extremity; near the base of the tail are situated several small ridges, or glandular receptacles, in which is secreted a yellowish fluid, resembling in smell the strongest civet; of this substance about the quantity of a scrip may, it is said, be obtained from each animal.

These creatures are said sometimes to be seen on the surface of the water in considerable numbers on the surface of lakes and rivers, and may often be heard to snap their mouths with a sound not unlike that of a duck; feeding on worms, leeches, water-insects, &c. as well as occasionally on vegetable substances. In some particulars this animal makes a distant approach to that most singular of quadrupeds, the platypus.

The musk-shrew is a slow-paced animal and cautious; it is accidentally found on land. The skins are said to be sold in Russia to put into chests in order to drive away moths; and so common is the animal in the neighbourhood of Niznym Novogorod, that the peasants are said to bring five hundred apiece to market, where they are sold for a shilling per hundred.

In the twelfth edition of the Systema Naturae this animal is placed in the genus casor or beavers of Castor muschatus. See Plate Nat. Hist. fig. 368.

3. Sorex radius, Canada shrew. This animal may with great propriety be termed sorex radius, since the snout, which is long and slaty, takes up the entire extremity, furnished with a circular series of sharp-pointed processes or soft tendrils, disposed in the manner of the rays in a spur. The whole animal is of a long form, and its habit immediately pronounces it to belong to the genus sorex, and not to that of talpa. Its body is longish, and covered with black coarish hair; the feet far less than those of a mole; the eyes hide under the skin; the snout either takes up the entire extremity, or the radiated tentacula at the end of the nose are of a bright rose-colour, and moveable at the pleasure of the animal, so as either to be brought together into a tubular form, or expanded in the form of a star.

It is said to inhabit Canada, but not to be very common there. It occasionally burrows somewhat in the manner of a mole, but far less strongly, or more slowly, and is said to pass through the depth of its burrow beneath the surface of the snow.

4. Sorex cretaceus, perfuming shrew, measures from nose to tail near eight inches; and the tail is about three inches and a half long. This animal diffuses a musky smell, however, these parts presently regain the position in which they were before the bell was struck; but as they return with an accelerated force, they generally go beyond the point where they ought to rest. The part a, the lower border of the sound, and is said to be directed towards s, and the parts b and d towards k and l; and whence it happens that the bell, at first of a circular form, really becomes alternately elliptic in two distinct times; it follows then, that in those parts where the curvature is the greatest, their exterior points depart from each other.

The same circumstance happens to the musical chord of a harp, or other stringed instrument, when it is touched; for, in order to become angular, as BCD or BDE (fig. 220) it is necessary that the string be stretched or lengthened, and consequently its particles be in some measure removed from the point of contact.

There are then two vibrations which take place in sonorous bodies: the general vibration, which changes the form of the body; and the particular vibration, which affects the minute particles, in consequence of the former. M. de la Hire has proved, that the sound is not owing to the natural vibration, but rather to the vibration of the particles; for whenever the two vibrations can be separated, it is found that the former produces no sound; but when the general vibration is accompanied with a vibration of the particles, it is the latter that regulates the duration, the force, and the modulation of the sound; if, on the contrary, these vibrations are stopped or interrupted by touching the sonorous body, the sound immediately ceases. On this account clock-makers attach to the hammer which strikes the bell of the clock a small spring, which elevates it again the moment it has struck, and prevents it from remaining upon the bell, which would considerably deafen or destroy the sound.

Acute sounds are produced, when the vibrations of the sounding body are more frequent; grave or deep sounds, when they are less so; no medium between acute and grave sounds can be found; and some sounds are said to be in unison when they vibrate with the same frequency; when one vibrates twice as fast as the other, they differ by an octave; and other ratios, with respect to the quickness of vibration, are distinguished by other names. Chords which are short and tightly stretched, produce acute sounds, those which are long and lax, grave sounds.

The motion or vibration of bodies at a distance to would not affect our sense of hearing without the medium of some other body, which receives an impulse from this motion, and communicates the vibration to our organs. Thus a hard blow upon an anvil or upon a bell could not be heard by us, even at a very small distance, if there was not a medium between those objects and us capable of transmitting the vibrations to our auditory nerves. Elastic fluids are the most effective mediums for this purpose, and consequently the air is the most common vehicle of sound; which is very easily proved by ringing a bell under the receiver of an air-pump, the sound it affords being found gradually to diminish as the air becomes exhausted, till at length it ceases to be heard.
at all. That the air is capable of being agitated with great force, appears from the violent concessions produced by explosions of gunpowder, as well as from the power, which some persons are known to possess, of breaking drinking-glasses, by means of their vocal organs, when sounded in unison with the note which the glass would have produced when struck. The tremulous motion excited in the air by sounding bodies, has been supposed analogous to the successive rings which are produced in a liquid by disturbing the surface of the water. This hypothesis, however, was disproved by the observation that sounds, whether weak or loud, always travel with the same velocity, which does not hold true with respect to the rings on the surface of water, since these move faster or slower according to the force of the cause which excited them.

Every sound is rendered stronger or weaker, and may be heard at a greater or less distance, according to the density or rarity of the elastic fluid by which it is propagated. According to Mr. Hanksbee, who has made deep researches into this branch of philosophy, when air has acquired twice its common density it transmits sound twice as far as in the case of rare air; whereas he reasonably concludes, that sound increases, not only in direct proportion to the density of the air, but in proportion to the square of this density.

If sound was propagated in an elastic fluid more dense than air, it would be carried proportionally farther. I have proved this, says M. Brison, by putting a sonorous body into carbonic acid or fixable air, the density of which is about one-third more than that of air; but the consequence was, that at that time, and in that situation, the sound was very considerably increased. For the same reason, the dryness of the air, which increases its density, has a considerable effect in rendering sound louder and more audible. Sound is also much increased by the reverberation of the pulses of the air from those surrounding bodies against which they strike, whence it happens that music is so much better heard in a close apartment than in the open air.

Elastic fluids are, however, not the only medium through which sound may be transmitted; for it may be propagated by means of water and other liquids, which may be proved by immersing a sonorous body in water; but it must be observed, that in this case the sound will be less perceptible, and will not extend to so great a distance; the cause of this diminution is, because mediums for the transmission of sound should be elastic, and that a property which water and other liquids possess only in a very restricted degree.

Sound is also transmitted by solid bodies; provided they possess a sufficient degree of elasticity to produce this effect. Light, we have already seen, is projected or reflected with incredible velocity; but sound is transmitted much more slowly, and its progression is very perceptible to our senses. The flash from a cannon, or even a musket, may be seen some seconds before the sound reaches our ears. As the motion of light, therefore, is instantaneous with respect to moderate distance, this has been the common means employed as acertaining the progress of sound. Sir Isaac Newton observes that "all sounding bodies propagating their motions on all sides by successive consecutive vibrations, if it be, is, by an alternate progression and return of the particles; and these vibrations, when communicated to the air, are termed pulses of sound. All pulses move equally fast. This is proved by experiment; and it is found that they pass through two hundred and forty-two feet in a second, whether the sound is loud or low, grave or acut.

Some curious experiments were made, relative to the propagation of sound, by Messeurs De Thury, Maraldi, and De la Caille, upon a line fourteen thousand six hundred and thirty-six fathoms in length, having the tower of Montmartre at the other extreme of that distance: their observations were placed between those two objects. The results of their observations were these: 1st. That sound moves one hundred and seventy-three fathoms, French, in a second, when the air is calm. 2d. That sound moves with the same swiftness whether it is strong or weak; for these gentlemen observed, that the dischgre of a box of half a pound of gunpowder exploded at Montmartre was heard at mount Liveri in the same space of time, as the report of a great gun charged with nearly six pounds of powder. 3d. That the motion of sound is uniform; that its velocity neither accelerates nor diminishes through all the intervals of its progress, as is the case with almost every other species of motion. The velocity of sound is the same, whether it is placed towards the person who hears its report, or turned in a contrary way; in other words, a great gun fired from the Tower of London eastward, would be heard at Westminster in the same interval of time as it was discharged towards the latter place. And if the gun was discharged in a direction perpendicular to the horizon, it would be heard as soon as discharged in a right line towards the hearer. By other experiments, however, the progress of sound appears to be impeded by a strong wind, so that it travels at the rate of about one mile slower in a minute, than it would have done in a vacuum.

A knowledge of the progression of sound is not an article of mere sterile curiosity, but in several instances useful; by this we are enabled to determine the distance of ships or other moving bodies. Suppose, for example, a vessel fires a gun, the sound of which is heard five seconds after the flash is seen: as sound moves 1142 English feet in one second, this number multiplied by 5, gives the distance of 5710 feet. The same principle has been applied to the lightning and thunder, as to calculating the distance of it from us. See Electricity.

The waves or pulses of sound being flexible in their course when they meet with an extended solid body of a regular surface, an ear placed at the passage of these reflected waves will perceive a change from the original sound, which will seem to proceed from a body situated in a similar position and distance behind the plane of reflection, as the real sounding body is before it. It is thus that we hear an echo, which, however, cannot take place at less than fifty-five feet; because it is necessary that the distance should be such, and the sound repeated by returning sound so long in arriving, that the ear may distinguish clearly between that and the original sound.

Reflected sound may be magnified by much the same contrivances as are used in optics respecting light: hence it follows, that sounds uttered in one focus of an elliptical cavity are heard much magnified in the other focus. The whispering-gallery at St. Paul's cathedral in London, is of this description; a whisper uttered at one side of the dome is reflected to the other, and may be very distinctly heard, and ear trumpets are constructed on this principle. The best form for these instruments is a hollow parabolic conoid, with a small orifice at the top or apex, to which the mouth is applied when the sound is to be magnified, or the ear when the hearing is to be facilitated.

The structure of the ear is one of the most complicated and difficult subjects of physiology; and the reader is, therefore, referred to that article for what concerns this branch of acoustic science.

Sound, Musical. Sounds of such qualities and dispositions as to produce that agreeable and appreciable effect upon the ear which we call melody, or harmony. We shall at present confine our observations to that affection of sound which it becomes distinguished into acute and grave.

This difference has hitherto appeared to have no other causes than the different velocities of the vibrations of the sounding bodies; in fact, the tone or pitch of a sound seems to have been discovered, by an abundance of experiments, to depend on the nature of these vibrations, whose difference we can conceive no otherwise than as having different velocities; and since it is proved, that all the vibrations of the same chord are performed in equal time; and that the tone of a sound, which continues for some time after the stroke, is the same from first to last; it follows, that the tone is necessarily connected with a certain time in making each vibration; and it is from this principle that all the phenomena of tone are deduced.

If the vibrations are isochronous, the sound is called musical; and is said to be acute, or higher, than any other sound whose vibrations are slower and graver, or lower than any other sound whose vibrations are quicker.

From the same principle arise what we call concords, &c. which are resolvable into the frequent unions and coincidences of the vibrations of two sonorous bodies, and consequently the undulations of the air which they occasion. On the contrary, the result of less frequent coincidences of those vibrations is what we call discord.

Another consequence of the union of musical sounds is, that by which they are denominated long and short; not with regard to the sonorous body's retaining a motion, once received, a longer or lesser time, but to the continuation of the impulse of the efficient cause on the sonorous body for a longer or shorter time; as in the notes of a violin, &c. which are made longer or shorter by strokes of different length or quickness.

This continuity is, properly, a succession of short sounds, or the union of several distinct strokes, or repeated impulses, on the sonorous body, so quick that we may judge
It one continued sound, especially if it is continued in the same degree of strength; and hence arises the doctrine of measure and time.

Sounds again are distinguished by musicians into simple and compound.

A simple sound is the single product of one voice, or one instrument.

A compound sound consists of the sounds of several distinct voices or instruments, all united in the same individual time and measure of duration, that is, all striking the ear together, whatever may be their other differences.

The natural compound is that proceeding from the manifold reflections of the first sound from adjacent bodies, when the reflections are not so sudden as to occasion echoes, but are all given at the same moment, as well as in the same tone, or pitch, with the first note.

The artificial compound, which alone comes under the musician's province, is that mixture of several different sounds, which being produced by art, the ingredients are separable, and distinguishable from one another.

In this sense the distinct sounds of several voices or instruments, or several notes of the same instrument, are called simple sounds, in contrast-those of the compound ones, in which, to answer the purposes of music, the simples must have such an agreement in all relations, chalybes to acuteness and gravity, as that the ear may receive the mixture with pleasure.

Sound, in geography, denotes in general any striving, or inlet, of the sea, between the two headlands.

Sound-board, in an organ, is a reservoir into which the wind, drawn in by the bellows, is conducted by a port-and-vent, and hence distributed into the pipes placed over holes in its upper part; this wind enters them by vales, which open by pressing upon the stops or keys; after drawing the registers, which prevent the air from entering any of the pipes, except those it is intended to.

Soundings, in navigation, the act of trying the depth of the water, and the quality of the bottom, by a line and plummet, or other appliances.

At sea there are two plumbets used for this purpose, both shaped like the frustum of a cone or pyramid. One of these is called the hand-lead, weighing about eight or nine pounds; and the other the deep-sea lead, weighing from 25 to 50 pounds. The former is used in shallow waters, and the latter at a great distance from the shore. The line of the hand-lead is 25 fathoms in length, and marked at every two or three fathoms, in this manner, viz. at two and three fathoms from the lead there are marks of black leather; at five fathoms a white rag, at seven a red rag, at ten and at thirteen black leather; at fifteen a white rag, and at seventeen a red one.

Sounding with the hand-lead, which the seamen call heaving the lead, is generally performed by the helmsman in the main-chains to windward. Having the piece of lead ready to run out, without interrupting it, he holds it nearly at the distance of a fathom from the plummet; and having swung the latter towards him for three or four times, in order to acquire the greater velocity, he swings it round high and then...

SPAR. See Fracture of lime.

Spar, in mineralogy, a name given to those earths which break easily into rhomboidal, cubical, or laminated fragments with polished surfaces, and which are composed of one or more of the following substances: quartz, stones of different kinds, without any regard to the ingredients of which they are composed, some additional term must be used to express the constituent parts as well as the figure; for instance, calcareous spar, gypsum, conchaneous spar, &c. The spar found in Britain and Ireland are of four different species, opake, refracting, diaphanous, and strata.

1. The opake spar is rhomboidal, hexagonal, and triangular, of various colours, and is found in mines in Wales, Derbyshire, &c. and at Ovens near Cork.

2. The refracting spar is rhomboidal, shows objects seen through it double, and sometimes S, L or other images at once. It is frequent in the lead-mines of Derbyshire, Yorkshire, &c.

3. Diaphanous spar is rhomboidal, triangular, hexagonal, pyramidal or columnar; and is found in mines, quarries, and caverns, in the so-called Stalactitic spar, or stalactites, which are formed by the running or dropping of water, containing a large proportion of calcareous earth. It is opaque, generally laminated, but from accidental circumstances it sometimes forms various forms. It occurs at Knaresborough in Yorkshire, and at Ovens near Cork.

A new species of spar has lately been found in the East Indies, which, from its extreme hardness, approaching to that of a diamond, is called adamantine spar. It was discovered by Dr. Black of Edinburgh to be a distinct species. Happening one day to visit a lapidary, it was shown to him among other specimens as a stone that was used in the East Indies for polishing guns, and grinding other hard substances. Dr. Black immediately singled out a specimen, which he sent to Mr. Greville, who requested M. Klaproth to analyse it.

There are various varieties of this spar; one of them comes from China, and crystallizes in hexagonal prisms without pyramids, the length of the sides varying from six to twelve lines; their breadth being about nine, of a grey colour, and with different species for their hearts, and sides up to the height of a yard, and the rest being made of brick, the hearth by the force of the fire is continually growing wider, so that it at first contains as much metal as will make a sowe of six or seven hundred weight, it will at last contain as much as will make a sowe of 2000 weight.

SOWANS. See STARCH.

SOWNE, a term used in the exchequer, where estreats that sowne not, are such as the sheriff by his care and diligence cannot levy, wherefore they are not regarded; and the estreats that sowne, are such as he may levy.

SPA. See Water, mineral.

SPACE, in geometry, denotes the area of any figure, or that which fills the interval or distance between the lines that terminate it.

SPACE, in mechanics, the line a movable body, considered as a point, is conceived to describe.

SPAN, a measure taken from the space between the thumb's end and the tip of the little finger, when both are stretched out. The span is estimated at 3 hand's-breadths, or 9 inches.
to the order of triandria, and in the natural system ranged under the 3rd order, Catar.

The aequinome of the male flower is furnished with two triangular stamens and there is no corolla. The aequinome of the female flower resembles that of the male. The stigma is bifid; the fruit is a dry berry containing one seed. There are three species, all of them native of Great Britain and Ireland, and growing in pools and lakes.

SPARMAIANA, a genus of plants belonging to the class of polynandra, and to the order of monogynia. The corolla consists of five petals, and is hemispherical. The stamens are numerous, and swell a little; the calyx is quadrangularly; the capsule is angulated, quinquelocular and echinate. There is only one species, the africanus, a shrub of the Cape.

SPARROW. See Fringilla.

SPARROW-HAWK. See Falco.

SPARTIUM, a genus of plants belonging to the class of diadephi, and order of decandria, and in the natural system arranged under the 32d order, papilionaceae. The flowers are gathered in the form of a long spike, and from the stipules, the adheres to the germin.

The calyx is produced downwards. There are 27 species. All these, except the scoparium, are races, chiefly from Spain, Portugal, Sicily, and Italy. The calyx, or common brown, is used for a variety of purposes.

It has been a great benefit sometimes in droppal complaints. The manner in which Dr. Cullen administered it was this: he ordered half an ounce of fresh brown, to be boiled in a pound of water till one-half of the water was evaporated. He then gave two tablet-spoonfuls of the decoction every hour till it operated both by stool and urine. By repeating these doses every day, or every second day, he says some droppies have been cured. Dr. Mead relates, that a droppal patient, who had taken the usual remedies, and been tapped three times without effect, was cured by taking half a pint of the decoction of quenb-brown tops, with a spoonful of white mustard-seed, every morning and evening. *An infusion of the seeds drunk freely (says Mr. Withering) has been known to produce much effect; but whoever expects these effects to follow in every droppal case will be greatly deceived.* I knew them succeed in one case that was truly deplorable; but out of a great many of cases in which the medicine had a fair trial, this proved a single instance.*

The flower-buds are in some countries pickled, and eaten as capers; and the seeds have been used as a bad substitute for cacao. The branches are used for making besoms, and tanning leather. They are also used instead of thatch to cover houses. The old wood furnishes the cabinet-maker with beautiful materials for veneering. The tender branches are in some places used in brewing, and the macerated bark may be manufactured into cloth.

SPARGELSTEIN, a mineral found in Spain, where it forms whole mountains, in different parts of Germany, and in Cornwall. It is sometimes amorphous, and sometimes crystallized. The primitive form of its crystals is a regular six-sided prism. Its integrant molecule is a regular triangular prism, whose base is the right angle. 

\[ \sqrt{2} \]

Sometimes the edges of the primitive hexagonal prism are wanting, and small faces in their place; sometimes there are small faces instead of the edges, which terminate the prism; sometimes these two varieties are united.

SPARUS, a genus of fishes of the order thoracis: the generic character is, the teeth strong; front teeth in some species disposed in a single row, in others in a double, triple, or quadruple row; graders (in most species) convex, smooth, and disposed in ranges, forming a kind of pavement in the mouth; lips thick; gill-covers unarmed, smooth, sally. The genus sparus is extremely numerous, there being more than 40 species, and as the greater number are exotic, very little is known of their history; a general survey is therefore all that can be expected; it may be observed that they are much allied to the labrus, and that the distinction between these two genera is not, in all cases, so clear as might be wished; in the Systema Naturae of Linneus an evident confusion takes place with respect to the characters of both.

Sparus aurata. Gill-head sparus. General, a fish of fifteen inches, but occasionally found of far larger size; body broad and thin, the back rising into a carina: native of the Mediterraneum, Atlantic, and Indian seas, and held in considerable esteem as a food, not only by the ancient Greeks and Romans, and by the former nation consecrated to Venus.

SPATHELIA, a genus of plants belonging to the class of pentandria, and order of decandria; the flowers are small, umbelas on the peduncle; the petals are pale; the capsule is three-edged and trilocular; the seeds solitary. There is only one species, the simplex, which is a native of Jamaica, and was introduced into the botanic garden of this country in 1778 by Dr. Wright, late of Jamaica.

SPASM. See Medicine.

STABULA, an instrument used by surgeons and apothecaries for spreading plasters, &c.

SPECIES, in algebra, the characters or symbols used of to represent quantities.

SPECIFIC, in medicine, a remedy whose virtue and effect is peculiarly adapted to some form of disease; and expuits its whole force immediately thereon.

SPECIFIC, in philosophy, that which is peculiar to any thing, and distinguishes it from all others.

SPECIOUS ARITHMETIC, the same with algebra.

SPECLARIS LAPIIS, in natural history, a genus of talcs, composed of large plates visibly separate, and of extreme thinness; and each fuscus again separated into a number of plates still finer. (See Talc.) Of this genus there are three species: 1. The white shining specularis, with large and broad leaves, commonly called iksinglass and Masscova glass; its fanacles, or leaves, are extremely thin, elastic, and transparent; it makes sometimes not the least effervescence with aquafortis, and is not easily calcined in the fire. It is imported in great quantities; the mineralogists suppose from the pictures with which they represent it; the glass-makers use it instead of horn; and minute objects are usually preserved between two plates of it, for examination by the microscope. 2. The bright-brown specularis, with broad leaves, resembling a great part of white arsenic. The 3. The purple bright specularis, with broad leaves, the most elegant of all the takes, and as beautifully transparent as the first kind.

SPECULUM, or looking-glass or mirror, capable of reflecting the rays of the sun, &c. See Optics: see also Foliating looking-glasses, vol. i. p. 738.

SPECULUM, in surgery, an instrument for disturbing a wound, or the like, in order to examine it attentively.

SPECULUM for reflecting telescopes, is made of a kind of white copper consisting of 32 parts of fine red copper, one of brass, fifteen of glass-tin, and inferior arsenic. The process, as given by the late J. Edwards, who was rewarded by the board of longitude for disclosing it to the public, was published in the Nautical Almanack for 1787, and is as follows: Melt the copper in a large crucible, employing some black flux, composed of two parts of tartar and one of niter; when melted, add to it the brass and silver. Let the pure tin be melted into another crucible, also with some black flux. Take them both, and put the melted tin into the fused mass in the large crucible. Stir the whole well with a dry spatula of birch; and pour off the fused metal immediately into a large quantity of water. The copper will cause the fluid metal to divide into an infinite number of small particles, which will cool instantly. 2. If the copper is completely saturated, the fracture of one piece of this mixed metal will be made up of a glossy look, resembling the face of pure quicksilver. But if it is a brown reddish colour, it wants a little more tin. To ascertain the required proportion, melt a small quantity, know by weight, of the mixed metal, with a known very small part of tin; and, if necessary, repeat the trial with different doses, till the fracture of the new mixture looks as already described. Having now ascertained the necessary addition of tin that is required, proceed to the last melting of the whole metal, together with the additional proportional dose of tin; fuse the whole, observing the same cautions as before, and you will find that the mixture is not with a truth of that for the first fusion. Have ready as many ounces of white arsenic in coarse powders as there are pounds in the weight of metal; wrap up the arsenic in a small paper, and put it, with a few pounds, into the crucible; stir it well with the spatula, retaining the breath to avoid the arsenical fumes or vapours (which however are not found to be hurtful to the lungs) till they disappear; take the crucible off the fire, clear away the dust from the top of the metal; pour in about one ounce of powdered rosin, with as much nitre, in order to give the metal a clean surface, and pour out the metal into the moulded flask. 3. The speculum should be moulded with the concave surface downwards, and many small holes should be made through the sand upwards, to discharge the air. The moulding-sand from Highgate near London, used by the founders, as is good, as any for casting these metallic mirrors. The cast metal should be taken out from the sand of the flasks whilst it is hot, or else it may happen to crack it left to cool within.

SPEEDWELL. See Veronica.

SPELTER. See Zinc.

SPELT. In the sea-language, signifies the same as broken.
SPERMULA, a genus of plants belonging to the class of cryptogams, and the order of psyllids, and in the natural system arranged under the 42d order, carophyllaceae. The calyx is pentaphyllous; the petals five, and ovuliferous ovary, or ovary, and being of a dark or white color, and containing five values. There are seven species, five of which are British:—

1. The arvensis, corn-spernum, has linear furrowed leaves, from eight to twenty in a whorl. The flowers are small, white, and terminal. It is frequent in corn-fields. In Holland it is cultivated as food for cattle, and has the advantage of growing on the poorest soils, but does not afford a great deal of food. Poultry are fond of the seeds; and the inhabitants of Finland and Norway make bread of them when their crops of corn fail. Horses, sheep, goats, and swine, eat it. Cows refuse it. 2. The nodosa, knotted spernum. 3. Pentandra, small spernum. 4. Laricina, larch-leaved spernum. 5. Sagittoides, pearwood spernum.

SPERMACETI. This peculiar oily substance is found in the cranium of the Physycter monocerophulus, or spermaceti-whale. It is obtained also from other species; first it is mixed with some liquid oil, which is separated by means of a woollen bag. The last portion is removed by an alkaline ley, and the spermaceti is afterwards purified by filtration. This obtained it is a beautiful white substance, usually in small scales, very brittle, has scarcely any taste, and but little smell. It is distinguished from all other fatty bodies by the crystalline appearance which it always assumes, when molten, according to the experiments of Bostock, at the temperature of 117°. When sufficiently heated it may be distilled over without much alteration; but when distilled repeatedly, it loses its solid form, and becomes a liquid oil. It is soluble in boiling alcohol, but separates again as the solution cools. About 150 parts of alcohol are necessary to dissolve it. Either dissolves it cold, and very rapidly when hot; on cooking it into a solid mass. It dissolves also in hot oil of turpentine, but precipitates again as the liquor cools.

The acids have hardly any action upon it, but it unites with the pure alkalis. With hot ammonium it forms an emulsion which is not decomposed by cooling nor by water. It dissolves sulphur, and is dissolved by the fixed oils.

SPERMACEOCE, button-wood, a genus of plants belonging to the class of Psilocyceae, and order of monomyceae, and in the natural system arranged under the 47th order, sel-laticae. The corolla is monopetalous and funnel-shaped, and there are two bidentate seeds. The species are 20, all store plants from warm climates.

SPERMACEUS. See Spermaceti.

SPHERANTHUS, a genus of plants belonging to the class of Syngenesia, and to the order of Polygonaceae; and in the natural system arranged under the 49th order, compositae. Each stalk of the calyx contains eight florets; the florets are tubular, the female being scarcely distinguishable. The receptacle is scaly; and there is no pappus. The species are four, the indicus, the alicuea, the cinnamomum, and another.

SPHERIA, a genus of the class and order Cryptogamia funga. The fructifications are mostly spherical, opening at the top; while young filled with jelly, when old with blackish powder. They grow on the bark or wood of other plants. There are 29 species.

SPHEROCARPUS, a genus of the Cryptogamia class of plants, and order alge, consisting of follicular matter, expanded on the ground, and producing very large and obvious fructifications. Dr. Hilt thinks it probable, that the male flowers are produced on separate plants from the female, and have not been discovered to belong to the same species: no male parts of fructification are described to us; the female parts consist of a tubulated and inflated vagina, within which is contained a large globular capsule, containing a great number of small loose seeds.

SPHAGNUN, bog-moss, a genus of plants belonging to the class of cryptogams and order of musci. The anthere are globose; the mouth entire, and closed by an operculum; the calyptra is wanting. There are several species, the unmun, and arboreum. 1. The palustre, common bog-moss, grows on our bogs in wide patches, so as frequently to cover a large portion of their surface. The stalks are from two inches to foot long, long-stalked, set with numerous, conical, pendant branches, and terminated with a rotaceous cluster of erect short ones. It is generally believed, that the roots and decayed stalks of this moss constitute a principal part of that useful bituminous substance called peat, which is the chief fuel of the northern regions. The Lapland nations are well acquainted with this moss. They dry and lay it in their cradles, to supply the place of bed-clothes, and every covering; and, being changed night and morning, it keeps the infant remarkably clean, dry, and warm. It is sufficiently soft to yield, but the tender mother, not satisfied with this, frequently covers the moss with the dry hair of the rein-deer; and by that means makes a most delicate nest for the young babe.

2. The alpinum, green bog-moss. Its branches are subulate and erect on the surface of mountain bogs in South Britain.

3. The arboreum, creeping bog-moss, is branched; the anthere are numerous, sessile, hairy, and grow along the branches chiefly on one side. It is found on the trunks of trees.

SPHENOIDAL SUTURE. See Anatomy.

SPHENOIDES. See Anatomy.

SPHERE, a solid contained under one uniform round surface, such as would be formed by the revolution of a circle about a diameter thereof as an axis. See Geometry.

Sphere, properties of the, are as follow:

1. A sphere may be considered as made up of an infinite number of pyramids, whose common altitude is equal to the radius of the sphere, and all their bases form the surface of the sphere. And therefore the solid content of the sphere is equal to that of a pyramid whose altitude is the radius, and its base is equal to the surface of the sphere, that is, the solid content is equal to the product of its radius and surface.

2. A sphere is equal to of its circumscribing cylinder, or of the cylinder of the same height and diameter, and therefore equal to the cube of the diameter multiplied by 3/4, or of the sphere of the same base and height. Hence all of different spheres are one another as the cubes of their diameters, and their surfaces as the squares of the same diameters.

3. The surface or superficies of any sphere, is equal to four times the area of its great circle, or of a circle of the same diameter as the sphere.

4. The surface of the whole sphere is equal to the area of a circle whose radius is equal to the diameter of the sphere. And, in this manner, the curve surface, whether greater or less than a hemisphere, is equal to a circle whose radius is the chord line drawn from the vertex of the segment to the circumference of its base, or the chord of half its arc.

5. The curve surface of any segment or zone of a sphere, is also equal to the curve surface of a cylinder of the same height with that portion, and of the same diameter with the sphere. Also the surface of the whole sphere, or of a hemisphere, is equal to the curve surface of its circumscribing cylinder. And the curve surfaces of their corresponding parts are equal, that are contained between any two places parallel to the base. And consequently the surface of any segment or zone of a sphere, is as its height or altitude.

Most of these properties are contained in Archimedes's treatise on the sphere and cylinder. And many other rules for the surfaces and solidities of spheres, their segments, zones, frustums, &c., may be seen in Bonnycastle's Mensuration.

Hence, if d denotes the diameter or axis of a sphere, s its curve surface, c its solid content, and a = 7.853 the area of a circle whose diameter is 1; then we shall, from the foregoing properties, have these following general values or equations, viz.

\[ s = \frac{4}{3} \pi d^2 \]
\[ c = \frac{4}{3} \pi d^3 \]
\[ a = \pi d^2 \]

Sphere, in astronomy, that conceve orb, or expanse, which invests our globe, and in which 't heavenly bodies appear to be fixed, and stand an equal distance from the eye.

Sphere, armillary. See Armillary Sphere.

Spherics, the doctrine of the sphere, particularly of the several circles described on its surface, with the method of projecting the same on a plane. See Projection of the Sphere.

A circle of the sphere is that which is made by a plane cutting it. If the plane passes through the centre, it is a great circle; if not, it is a little circle.

The pole of a circle, is a point on the surface of the sphere, equidistant from every point of the circumference of the circle. Hence every circle has two poles, which are diametrically opposite to each other; and all circles that are parallel to each other have the same poles.

Properties of the circles of the sphere.

1. If a sphere is cut in any manner by a
plane, the section will be a circle; and a great circle when the section passes through the centre, otherwise it is a little circle. Hence all great circles are equal to each other; and the line of section of two great circles of the sphere, is a diameter of the sphere; and therefore two great circles intersect each other in points diametrically opposite; and make equal angles at those points; and divide each other into two equal parts; also any great circle divides the whole sphere into two equal parts.

2. If a great circle is perpendicular to any other circle, it passes through its poles. And if a great circle passes through the pole of any other circle, it cuts it at right angles, and into two equal parts.

3. The distance between the poles of two circles is equal to the angle of their inclination.

4. Two great circles passing through the poles of another great circle, cut all the parallels to this latter into similar arcs. Hence, an angle made by two great circles of the sphere, is equal to the angle of inclination of the planes of these great circles. And hence also the lengths of those parallels are to one another as the sizes of their distances from their parallel great circle. Consequently, as radius is to the cosine of the altitude of any point on the globe, so is the length of a degree at the equator, to the length of a degree in that latitude.

5. If a great circle passes through the poles of another, this latter also passes through the poles of the former; and the two cut each other perpendicularly.

6. If two or more great circles intersect each other in the poles of another great circle; this latter will pass through the poles of all the former.

7. All circles of the sphere that are equally distant from the centre, are equal; and the farther they are distant from the centre, the less are they.

8. The shortest distance on the surface of a sphere, between any two points on that surface, is the arc of a great circle passing through those points. And the smaller the circle is that passes through the same points, the longer is the arc of distance between them. Hence the proper measure, or distance, of two places on the surface of the globe, is an arc of a great circle intercepted between the same. See Theodosius, and other writers on spheres.

SPHEROID, a solid body approaching to the figure of a sphere, though not exactly round, but having one of its diameters longer than the other.

This solid is usually considered as generated by the rotation of an oval plane figure about one of its axes. If that is the longer or transverse axis, the solid so generated is called an oblate spheroid, and sometimes prolate, which resembles an egg, or a lemon; but if the oval revolves about its shorter axis, the solid will be an oblate spheroid, which resembles an orange, and in this shape also is the figure of the earth, and of the other planets.

The axis about which the oval revolves, is called the fixed axis, and the other is the revolving axis, whichever of them happens to be the longer.

When the revolving oval is a perfect ellipse, the solid generated by the revolution is properly called an ellipsoid, as distinguished from the spheroid, which is generated from the revolution of any oval whatever, whether it be an ellipse or not. But generally speaking, in a common acceptance, the term spheroid is used for an ellipsoid; and therefore, in what follows, they are considered as one and the same thing.

Any section of a spheroid by a plane, is an ellipse (except the sections perpendicular to the fixed axis, which are circles); and all parallel sections are similar ellipses, or having their transverse and conjugate axes in the same constant ratio; and the sections parallel to the fixed axis are similar to the ellipse from which the solid was generated.

For the surface of the spheroid, whether it is oblong or oblate,

Let $f$ denote the fixed axis, and $r$ the revolving axis,

$$ e^2 = \frac{a^2}{b^2} - 1, \quad \text{and} \quad f = \frac{b}{r}; \quad \text{then will be expressed by the following series, using the upper signs for the oblong spheroid, and the undetermined for the oblate one, viz.}

$$

$$

The term \( \cos \theta \) is equal to the area of the generating ellipse, which appears that the surface of the oblong spheroid is less than 4 times the generating ellipse; but the surface of the oblate spheroid is greater than 4 times the same; while the surface of the sphere falls in between the two, being just equal to 4 times its generating circle.

Huygens has given two elegant constructions for describing a circle equal to the superfluities of an oblong and an ovate spheroid, which he says he found out towards the latter end of the year 1657.

Of the solidity of a spheroid. Every spheroid, whether oblong or oblate, is, like a sphere, exactly equal to two-thirds of its circumscribing cylinder. So that, if $f$ denotes the fixed axis, and $r$ the revolving axis, and $a = 7834$; then $\frac{4}{3}fr^2$ denotes the solid content of either spheroid. Or, which comes to the same thing, is done by the transverse and $c$ the conjugate axis of the generating ellipse; then $\frac{4}{3}c^2$ is the content of the oblate spheroid, and $\frac{4}{3}a^2$ is the content of the oblate spheroid.

Consequently, the proportion of the former solid to the latter, is as $c$ to $a$, or the less axis to the greater.

Further, if about the two axes of an ellipse are generated two spheres and two spheroids, the four solids will be continued proportionals, and the common ratio will be that of the two axes of the ellipse; that is, as the greater sphere, or the sphere upon the greater axis, is to the oblate spheroid, so is the oblate spheroid to the oblong spheroid, and so is the oblong spheroid to the less sphere, and so is the transverse axis to the conjugate.

SPHEROID, universal, a name given to the solid generated by the rotation of an ellipse about some other diameter, which is neither the transverse nor conjugate axis.

SPIFIEX, a genus of insects of the order hymenoptera. The generic character is, mouth with jaws, without tongue; antenna of ten joints; wings flat-inclined (not more than six in a line) united. As the insects of the genus spinex deposit their eggs in the bodies of other living insects, so those of the genus spicex deposit theirs in dead ones, in order that the young larvae, when hatched, may find their proper food.

1. Thus the spinex fugitus of Linnaeus, having found some convenient cavity for the purpose, seizes on a spider, and having killed it, deposits it at the bottom: then laying her egg in it, she closes up the orifice of the cavity with clay: the larva, which resembles the maggot of a bee, having devoured the spider, spins itself up in a dusky silken web, and changes into a chrysalis, out of which, within a certain number of days, proceeds the complete insect, which is of a black colour, with a slightly foot-stalked abdomen, the edges of the several segments being of a brighter appearance than the rest of the body. It should be noted that the female spinex prepares several separate holes or nests as before mentioned, in each of which she places a dead insect and an egg: each cell costing her the labour of about two days. See spinex fugitus of Linnaeus, which is of a black colour and slightly hairy, with brown wings, and the fore part of the abdomen ferruginous with black bands, seizes or tries in a similar manner, burying one in the ground, in which she deposits an egg, and then closes up the cell.

2. Spicex sabulosus Lin. is a black and hairy species, with the second and third joints of the abdomen ferruginous. It inhabits sandy and gravelly places, in which the female digs holes with her fore-feet, working in the manner of a dog, in order to form the cavity, in which she places either a spider or a caterpillar; after which she closes up the cavity, having first laid her egg in the dead insect. Linnaeus, in his description of this insect, contradicts the generic character, since he observes that it has a retractile snout containing the tongue.

3. One of the extra-European sphinx are insects of a very considerable size. The whole genus is very much allied to those of vespa and apis. There are 3 species. See Plate Nat. Hist. fig. 369.

SPHINX, the hawk moth, a genus of insects of the order lepidoptera. The generic character is, antennae thickest in the middle, subtrisymmetric, and attenuated at each extremity; wings delicately; slight, strong, and commonly in the evening or morning. The insects of this genus have in general a large thorax and thick body, commonly tapering towards the extremity. The male sphinx is applied to the genus on account of the posture assumed by the larva of several of the larger species, which are often seen in an attitude much resembling that of the Egyptian sphinx, viz. with the fore parts elevated, and the rest of the body applied flat to the surface.

1. One of the most elegant insects of this genus is the sphinx ligustri, or privet hawk moth. It is a large insect, measuring nearly four inches and a half; its head and wings a foot and a half long; the revolving axis of the ellipse about some other diameter, which is neither the transverse nor conjugate axis.
and body are of a fine rose-colour, banded with transverse black stripes. The caterpillar, which is very large, is smooth, and of a fine green, with seven oblique purple and white stripes along the ventral surface of the body, or top of the last joint, a horn or process pointing backwards. This beautiful caterpillar is often found in the months of July and August feeding on the privet, the lilac, the poplar, and some other trees, and generally changes to a chrysalis in August or September, retiring for that purpose to a considerable depth beneath the surface of the ground, and, after casing its skin, continuing during the whole winter in a dormant state, the sphinx emerging from it in the succeeding June.

2. The sphinx ocellata is perhaps still more beautiful: it is rather a smaller insect than the preceding, and has the upper wings and body brown, the former finely clouded with different shades, while the lower wings are of a bright rose-colour, each marked with a large ocellated black spot with a blue interior circle, and black bands of irregular width. It perhaps emerges from a green caterpillar of a rough and shagreen-like surface, marked on each side by seven oblique yellow-white streaks, furnished, like the preceding, with a horn at the tail. It has a curious appearance, the abdomen rises under green, in order to undergo its change into the chrysalis state, in the month of August or September; and in the following June appears the complete insect.

3. Both the foregoing, with that which is the most remarkable, if not the most beautiful European insect of this genus, is the sphinx atropos of Linnaeus, see Plate Nat. Hist. fig. 376, which very considerably exceeds in size both the species already mentioned. The upper wings are of a fine dark-grey colour, with a few slight variegations of dull orange and white; the under wings are of a bright orange-colour, marked by a hair of transverse black bands; the body is also orange-coloured, with the sides marked by black bars, while along the top of the back, from the thorax to the tail, runs a broad blue-grey stripe; on the top of the thorax is a very large patch of most singular appearance, the shape of an irregular, oblong figure of a skull or death's-head, and of a pale grey, varied with dull ochre-colour and black. When in the least disturbed or irnted, this insect emits a sulphurous, something like the smell of the male European mouse; and from this circumstance, as well as from the mark above-mentioned on the thorax, is held in much dread by the vulgar in several parts of Europe, its appearance being regarded as a kind of ill omen, or harbinger of approaching fate. We are informed by the celebrated Réaumur, that the members of a female convent in France were thrown into great consternation at the appearance of one of these insects, which happened to fly in during the evening at one of the windows of the dormitory. The caterpillar from which this curious sphinx proceeds is in the highest degree beautiful, and far surpasses in size every other European insect of the kind; measuring sometimes near five inches in length, and being of a very considerable thickness: its colour is a bright yellow, the sides marked by a row of seven most elegant broad stripes, or bands, one of which is purple, the other orange; the body is covered with a fine hair, and the head has a distinct mandible or hook. This caterpillar is principally found on the potato and the jessamine, those plants being its favourite food. It usually changes into a chrysalis in the month of September, retiring for that purpose pretty deep under the surface of the earth; the chrysalis state continues from the following June or July. The sphinx aitropos is generally considered as a very rare insect; and as the caterpillar feeds chiefly by night, concealing itself during the day under leaves, &c., it is not often detected.

We shall not conclude the survey of the genus sphinx without observing, that it contains some species of a smaller size, and of a somewhat different habit from the kinds above described. Among these is the beautiful sphinx filipes nudula, or dropwort sphinx, common in meadows towards the decline of summer, and which is distinguished by having the upper wings of an oblong-oval shape and of a dark shining green colour, with blood-red spots, and the lower wings red with a dark green edging; the caterpillars of a pale yellow, with rows of squarish black spots, and often seen feeding on various meadow-plant and grasses. The body is perfectly rounded, but not much broader than long, and encloses itself in an oval shining yellow web of silk, attached to the stem of some grass, &c. In this it changes into a chrysalis, out of which in about the space of three weeks appears the complete insect. See Plate Nat. Hist. fig. 371.

Others of the smaller sphingies are remarkable for having the wings in a considerable degree transparent; of this kind is the sphinx filipes, a variety of which is at first sight more resembling that of a wasp or hornet than of a sphinx, the wings being transparent with merely a slight edging of brown, and the thorax and abdomen varied with black and yellow. The caterpillar inhibits the hollows of poplar, sallow, willow, and lime trees, feeding on the substance of the bark; changing to a chrysalis in April, and the fly appearing in the month of June.

Sphinx crathorniformis is so much like the former as scarcely to be distinguished from it, and inhabits the hollows of the sallow and other willows, feeding on the wood: it changes to a chrysalis in May, and the fly appears in the month of July.

SPICA VIRGINIS, a star of the first magnitude, in the constellation Virgo. SPIDER. See ARAEAE. SPIDER'S WEB. See Silk. SPIDER'S WEBS. See Poisons. SPIELMANNIA, a genus of the diynamia angioperipera class and order. The calyx is five-cleft; corolla bearded at the throat, with five-cleft border; drupe with a twocelled, two-seeded nut. There is one species, a shrub of the Cape. SPIES, in war, are persons employed to give intelligence of what the enemy is doing. By making a proper use of the necessary creatures, the most secret designs of an enemy may be discovered, the positions his army are to take, the stations of his fleets, and even the manner in which the former is to be secured by masked batteries, or the latter be kept firm with chain-moosings, was the case of Boulogne in 1800. If they are apprehended, they immediately suffer death.

SPIGELLA, worm grasses, a genus of plants belonging to the class of pentandria, and order of the Cleridae, a family of the Blandine system arranged under the 47th order, stellate. The corolla is funnel-shaped; the capsule is bicylous, bilocular, and polyspermous. There are two species, the antheochis and maestrichtia. 1. The antheochis, see Plate Nat. Hist., fig. 179, the European worm-grass, growing in the months of July and August, in quite dry situations, and the greatest heights are found. This plant is generally found in low dry lands, after they have been turned up some months, and after great rains; its taste is herbaceous, and somewhat cliening; its growth is soft and flexible; its stalk hollow, smooth, and roundish. Its medicinal qualities are highly spoken of by Dr. Brown. 2. The maestrichtia, perennial worm-grass, or Indian pink. Its stem is four-cleft, and all the leaves opposite. Dr. Garden gave it in what he calls continued or remitting low worm-fivers, and found its efficacy promoted by the addition of rad, sesquiterp. virg.

SPIKING up the ordnance, a sea-phrase, used for fastening a quoin with spikes to the deck close to the breach of the carriages of great guns, that they may keep close and firm to the ship's sides, and not get loose when the ship rolls, and by that means endanger the breach of the head of the ordnance. SPILANTHUS, a genus of plants belonging to the class of syngeanis, and to the order of polygamia equales. The common calyx is ointment; the leaflets numerous, sub-oval, and obtuse, the two exterior leaves longer than the rest. The calyx is almost equal; down two-toothed, rectangular, conical, cleft. There are nine species, annuals of hot climates. SPINACIA, spingus, a genus of plants belonging to the class of dicrcea, and to the order of pentandria; and in the natural system arranged under the 12th order, holocarceae. The male calyx is quinqupartite; there is no corolla; the female calyx is quindrid; no corolla; there are four styles, and one seed within the indurated calyx. There are only two species, the ocearea and fera. 1. The ocearea, common spingus, has sessile fruits and sagittated leaves. It has been cultivated in Britain since 1568, but it is not known from what country it was originally brought. When intended for winter use, it should be sown on an open spot of ground in the last week of April, and the sowing should be done. If possible, when the weather is rainy. The way of gathering it to advantage is only to take off the longest leaves, leaving those in the centre to grow bigger; and at this rate a bed of the wild spingus will give a good crop a whole winter, till the spingus sown in spring is become fit for use, which is commonly in April. 2. The fera, wild spingus, produces its fruit on footstalks.

SPIN.C See Botany. SPINALIS. See Anatomy. SPINDLE. See Anatomy. SPINDELLE, in the sea language, is the smallest part of a ship's capstan, which is blessed the two decks. The spindle of the jero capstan has wheel to leave the wheel. The axis of the wheel of a watch or clock is also called the spindle. Among miners, the spindle is a piece of wood fastened into either stone-blade.

SPINDE-SHELL. See Buccinum. SPINE. spina dorsi. See Anatomy. SPINEL. This stone, which comes from the island of Ceylon, is usually crystallized. The form of its integral particles is the tetrahedron, the primitive form of its crystal, and a regular octahedron, composed of two four-sided pyramids applied base to base, each of
the sides of which is an equilateral triangle.
In some cases two opposite sides of the pyramids are broader than the other two; and sometimes the edges of the octahedron are wanting, and narrow faces in their place. For figures of this description, and others of various and other species of these crystals, the reader is referred to Romé de Lisle and the Abbé Estener. It occurs also in tetrahedrons, in rhomboids whose faces have angles of 120° and 60°, in rhomboidal dissociations, and in four-sided prisms terminated by four-sided pyramids.

The texture of the spinel is foliated. Fracture conchoidal. Its lustre is 3. Transparency 2 to 4. It causes a single reflection. Hardness 13. Specific gravity 3.570 to 3.625. Colour red, of various shades; sometimes also blue, green, and yellow. The constituents of the spinel are, according to Lessing.

SPINIFEX, a genus of plants belonging to the class of polygonia and order of dicotia. The hemaphroditic flowers have a calyx with bivalved bilocular glumes, the vallvettes being parallel to the rachis; the corolla is bivalved and awned; there are three stamens and two styles. In the male flowers the calyx is common with the hemaphroditic; the corolla and stamina are similar. There is only one species, the Squarrosum, a grass of the East Indies.

SPINNING, the act of reducing silk, flax, hemp, hair, wool, or other matter, into thread. Spinning is either performed on the wheel, or by a distaff and spindle, or with other machines proper for the several kinds of working. Hemp, flax, nettle-thread, and other like vegetable matters, are to be wadded in spinning: silks, wools, &c. are spun as in the preceding. The threads are not to stand in need of water; there is, however, a way of spinning or reeling silk as it comes off the cases or balls, where hot, and even boiling, water is to be used. The vast variety, and importance of these branches of our manufactures, which are produced from cotton, wool, and flax, spun into yarn, together with the cheapness of provisions, and the low price of labour, in many foreign countries, which are the rivals of our trade, have occasioned many attempts at home to render spinning more easy, cheap, and expeditious. Mr. Arkwright has carried the invention to a high degree of perfection. He not only contrived methods for spinning cotton, but obtained a patent for making cotton, flax, and wool, into yarn.

SPINSTER, in law, an addition usually given to all unmarried women from a viscount's daughter downwards.

The principal genus of vermes of the order mollusca. The generic character is, body projecting from a tube, jointed, and furnished with dorsal fins; peduncles or feet rough with bristles, and placed towards the back; heads two, long, simple; eyes two, oblong.

There are two species, viz. 1. The seticornis, which inhabits the ocean where there is a clayey bottom, is about three inches long: the tube is composed of agglutinated particles of earth, thin, erect, and three as long as the body. In this the animal projects its capillary white feeders, in search of food, which consists of marine worms. 2. Filicornis, that inhabits the Greenland seas: tube fragile, erect, greenish, from which it projects its feeders in search of planaria and other small marine worms.

SPIRACULA, in entomology, holes or pores on each side of every segment of the abdomen, through which insects breathe.

SPIRA-l, in geometry, a curve line of the circular kind, which, in its progress, recedes from its centre.

A spiral, according to Archimedes, its inventor, is thus described: If a right line, as AB (Plate Misc. fig. 222), having one end fixed at B, is usually moved round, so as with the other end A to describe the periphery of a circle; and, at the same time, a point is conceived to move forward equally from B to A, in the right line BA, so that the point describes that line, while the line generates the circle: then will the point, with its two motions, describe the curve-line B 1, 2, 3, &c. which shall be the helix a 1, 2, 3, &c. of the spiral line; and the plane space, contained between the spiral line and the right line BA, is called the spiral space.

If also you conceive the point B to move twice as slow as the line AB, so that it shall get but half-way along the line BA when that line shall have formed the circle; and then you imagine a new revolution to be made of the line carrying the point, so that they shall end their motion at last together: there will be given a second spiral line, and the twined a second series of spatial spaces, as you see in the figure. From the genesis of this curve, the following corollaries may be easily drawn. 1. The lines B 1, B 11, B 10, &c. making equal angles with the first and second spirals (as also B 12, B 10, B 8, &c.), are in arithmetical proportion.

2. The lines B 7, B 10, &c. drawn by the first spiral, are to one another as the arches of the circle intercepted between BA and those lines. 3. Any lines drawn from B to the second spiral, as B 18, B 22, &c. are to each other as the aforesaid arches, together with the whole periphery added on both sides. 4. The first spiral space is to the second spiral space as 1 to 3. And 5. The first spiral line is equal to half the periphery of the first circle; for the radii of the sectors, and consequently the arches, are in a simple arithmetical progression, while the periphery of the circle contains as many arches equal to the greatest; whereas the periphery to all those arches is to the spiral lines as 2 to 1.

SPIRAL, in architecture and sculpture, implies a curve that ascends, winding about a cone or spire; so that all the points thereof continually approach the axis. It is distinguished from the helix, by its winding about a cone, whereas the helix winds in the same manner round a cylinder.

SPIRALS, proportional, are such spiral lines as the rhomboid-lines on the terrestrial globe, which because they make equal angles with every meridian, must also make equal angles with the meridians in the stereographic projection on the plane of the equator; and therefore will be, as Dr. Halley observes, spontaneous spirals about the polar point. See RIBBON.

SPIRITS, ardent. See ALCOHOL. SPIRITUALITIES of a bishop, are the profits that he receives as a bishop, and not as head of parliament; such are the duties of his vocation, presentation-money, what arises from the institution and ordination of priests, the income of his jurisdiction, &c. See SPIRIT, or CUCKOW SPTT. See CADE.

SPLENUM, a genus of plants belonging to the class of cryptothalia, and order of muscit. The anthere are cylindrical, and grow on a large coloured apophysis or umbiliculum. The calyptra is caducous. The flower-stalk grows on a short peduncle. There are six species, the rubrum, luteum, sphericum, ampullaceum, vasculoso, angustatum. See SPIRIT. See SALVIA. See SPILEN. See SPLEEN.

SPlicing, in the sea-language, is the twisting the ends of two cables or ropes, and working the several strands into one another by a field, so that they become as strong as if they were but one rope, &c.

SPONDEE, spoudaine, in ancient poetry, a foot consisting of two long syllables, as omnes. Some give the appellation spodinai to verses composed wholly of spondees, or at least end with two spondees; as, Const., alique occults Pythia aganna circumspect.

SPONDIAS, hog-plum, a genus of the decandria pentagynia class of plants, the flower of which consists of five ovated, plane, and patent petals; and its fruit is an oval berry, containing four nuts in each cell. It is called mombin by Pliny. There are four species, trees of the West Indies.

SPONDYLYUS, a genus of testaceous mussels. The generic character is, a mollusc; shell tetthy; shell hard, solid, with unequal valves; one of the valves convex, the other rather flat; hinge with two recurved teeth, separated by a small hollow. There are four species. The gregarious, which has a shell slightly curved and spinous, inhabits the Indian and other seas, and is found in infinite varieties as to size, thickness, and colours; sometimes entirely purple, orange, white, or bluish-green; sometimes striped with various streaks. See Plate Nat. Hist. fig. 373.

SPONGIA, sponge, in natural history; a genus of animals belonging to the class of vermes, and order of zoophyta. It is fixed, flexible, and very torpid, growing in a variety of forms, composed either of reticulated fibres, or masses of small spines interwoven together, and clothed with a living gelatinous flesh, full of small mouths or holes on its surface, by which it sucks in and abstracts its nourishment.

Fifty species have already been discovered, of which 10 belong to the British coasts. 1. Oenula, see Plate Nat. Hist. fig. 374, or branched sponge, is delicately soft and very much branched; the several branches are covered with a greenish, prickly, and often united to

SPROUT, or EQUIVOCALE GENERATION. See EQUIVOCALE GENERATION.
in immense pressure; while the heat may be continued to a considerable degree in the cavity, without doing any alteration in the formable phenomenon of a volcanic fire. It must be acknowledged that it is in volcanic regions, that tepid waters are found in the greatest quantity; and it is in these that they display the most striking phenomena. At Laugavarn, a small lake, two days journey from mount Hecla, in Iceland, there are hot spouting springs, one of which throws up a column of water to the height of twenty-four feet. A mixture of mud and some-almost solid are always boiled to pieces, in six minutes, in one of these springs. At Geyser in the same island, there are forty or fifty spouting springs within the compass of three miles; in some the water is impregnated with clay, and white in its appearance; in some, where it passes through a fine ochre, it is as red as scarlet; in some it spouts forth in a continued stream; in others, at intervals like an artificial jet-d'eau. The largest which Von Troll observed had an aperture nineteen feet in diameter, through which the water spouted, at intervals, nine or ten times a day; round the top of it is a basin, which, together with the pipe, is in the form of a cauldron; the margin of the basin is nine feet higher than the conduit, and its diameter fifty-six feet. The water was thrown up in an immense column, at different times, to the height of from thirty to sixty feet, and returned to the height of ninety-two feet; previously to this explosion the earth began to tremble in three different places, and a noise was heard like a battery of cannon.

Another writer states, that at Geyser, in Iceland, there springs up a hot water, which upon cooling, deposits silicious earth; and that of this very water it has formed for itself a crater, in which columns of water, of a stupendous bulk, after they have been thrown to the height of ninety feet and upwards, fall, and are again received. The heat of the water during the explosion cannot be measured; but after it has risen and fallen through a stratum of earth, it is thick enough to raise the water to 212°, which evinces that the heat in the bowels of the earth must be much more intense; and at this we shall cease to wonder when we consider, that in some parts of Africa a subterraneous fire acts upon the water in caverns closed up by very thick strata of stones, so apparatus far more effective than Papin's digester.

The crater was at first unobstructed, and is daily strengthened, by silicious earth, which quits the monument on its being cooled, falls down, and, being in somewhat like a soft state, concretes. About sixty yards from the shore of the island of Hecla, at a place called St. Angler, a column of boiling water bubbles on the surface of the sea with great force, and communicates its heat to the water of the sea near it. It boils in winter and summer, and is of great use to the inhabitants in boiling their planks for ship-building, &c. The fishermen also frequently employ this curious cauldron to boil their fish.

Near the shore of this island sir William Hamilton found, when bathing in the sea, many spots where the sand was as thin as tinfoil, and under his feet as to oblige him hastily to retire.

There is also a boiling spring near Viterbo, in the Roman state, called the Ballicante. It is a circular pool of about sixty feet in diameter, in the middle of which there is a conical figure of which the water is constantly boiling. It is situated in a plain surrounded by volcanic mountains. A stone concretion floats on the surface of the pool, which being carried off by the superfluities of water, is deposited, and is constantly forming a tub of tuffa, of which the soil all around the pool is composed.

These fountains are best accounted for by supposing the pipe or conduit to communicate with a large reservoir of water, which being subject to the influence of the volcanic fire, the steam generated in the reservoir by the boiling of the water acts forcibly on the water in the shaft or pipe, and ejects it by its elastic force in the form of a fountain, which will act with more or less vigour according to the degree of heat, and according to the resistance which the water encounters in its passage.

The most singular circumstance is the number of these springs which are found in almost every country; and even in those countries which have long ceased to be volcanic. England itself has its tepid springs, and those of Bath, Buxton, &c, are well known. Camden mentions, a well near Wigan, in Lancashire, which was called the burning well. It is said, when it is in its suface, a flame was excited like that of ardent spirits set on fire, and the heat and inflammation thus excited would continue sometimes for the space of a whole day, and were sufficient to boil eggs, and cause the water to evince the well as having lost its inflammable property in his time; but he notices two other of a similar description, one in the same neighbourhood, and another in Shropshire. Should, then, the fact be as it is related by Camden, the philosophic reader will not find it difficult to explain the cause. The country where the well is, or was shutted, abounds in coal. The well is therefore impregnated with naphtha, or some bituminous vapour; this, upon the application of an ignited body, is capable of inflammation, and can even communicate a considerable portion of heat to the water of the well itself. There is no proof, however, that the Buxton spring above mentioned is impregnated with any bituminous matter, though coals are plentiful in the neighbourhood; and as these waters contain a small portion of iron, there is reason to suppose them to be capable of exciting pyrites, or combustible phosphorus, with a latent subterraneous fire. On the whole we are not sufficiently acquainted with the internal parts of the earth to account satisfactorily for these and other phenomena of a similar kind; and whatever is advanced in the way of theory on these topics should be advanced with becoming diffidence, and rather with a view of exciting the attention and curiosity of others, than for the purpose of establishing a system unsubstantiated by experiment, or building a reputation on the fallible basis of mere hypothesis. See Waters, Mineral.

Spring, in mechanics, denotes a thin piece of tempered steel, or other elastic substance; which, being wound up, serves to put several machines in motion, and several others to keep in action, in endeavour to unbalance itself: such is the spring of a clock, watch, &c.

The spring of a lock, gun, or pistol, is a piece of steel, violently bent; which, being at liberty, heats back the bolt of the lock, or strikes down the cock.

SPRINGING, of a nest, in the sea language, is when it cracks, but is not broken in any part of it; as the partners, bounds, &c.

SPRUCE-BEER, a cheap and wholesome liquor, which is thus made: Take of water sixteen gallons, and boil the half of it. Put the water thus boiled, while in full heat, to the cold part, which should be put into a barrel, or other vessel; then add sixteen pounds of treacle or molasses, with a few table-spoonfuls of the essence of spice, stirring the whole well together: add half a pint spirits, mixtures on each side, let it sit, with thebung-hole open, for two days, till the fermentation is abated. Then close it up, or bottle it off, and it will be fit for being drunk in a few days afterwards. In North America, and perhaps in other countries, where the black and white spruce-tars abound, instead of adding the essence of the spice at the same time with the molasses, they make a decoction of the leaves and small branches of these trees, which is equally good. It is a powerful antiscorbutic, and may prove very useful in long sea voyages.

SPUNGE. See SPONGIA.

SPRUNGING, in gunnery, the cleaning a gun's inside with a sponge, in order to prevent the sparks of fire from remaining in it, which would endanger the life of him who should load it.

SQUALLS, the shark, a genus of fishes of the order nantes. The generic character is; mouth situated beneath the anterior part of the head, with numerous teeth disposed in rows, spirals, or small hooks on each side, in most species five in number, of a semilunar shape. Body oblong, somewhat cylindrical. The animals of this genus are said to be much rarer in the Baltic than in any other sea; they are viviparous, and are observed to produce more young at a time than the rays, but each included, as in those fishes, in a quadrangular capsule or involucrum, each extremity of which is extended into a long, contorted, carinated, and thread of white. Many of the sharks are said to emit a phosphoric light during the night; they are chiefly of a solitary nature, and, in general, devour with indiscriminating voracity, almost every animal, whether in water or land, and some few species however are observed to feed chiefly on fish and other marine vegetables. There are 34 species, the most remarkable of which are,

Squalus carnaries. White shark. The great or white shark, so remarkable for its vast size and its powers of destruction, is an inhabitant of most parts of the globe; though much more frequently seen in the warmer than in the colder latitudes, and is said to reside principally in the depths of the ocean, whence it rises at intervals in order to prowl for prey, and is considered as the most voracious of all the inhabitants of the deep. It arrives at the length of more than thirty feet, and is of a somewhat thicker or broader form than most of the genus: the head is of a deformed shape, and broad; terminating in front in an obtusely pointed snout; the mouth is vast, and furnished on the margin of each jaw with from three to six rows of strong flat, triangular, sharp-pointed, and finely serrated teeth, which are so imbedded in their investing cartilages as to be either raised or depressed at pleasure: the tongue is broad, thick, and
SQUALLUS.

3. Squalus caulator. Spotted shark. Lesser spotted dog-fish. Habit rather slender; length from two to three feet; head large; snout prominent, and slightly pointed; skin rough; body cylindrical; colour pale-brick-red, marked with dusky spots, small, rounded, blackish, or dusky spots; teeth in a shelf of about thirteen young at a time, is very numerous on our own coasts, and very injurious to the fisheries; the liver is said to be highly nutritious, causing long-continued stupor, succeeded by an universal itching, with a total desquamation of the cuticle.

4. Squalus stellaris. Rock shark, or greater spotted dog-fish. The general colour of this animal is a reddish grey, with round, unal, blackish spots scattered over the whole body. The male and female are said to differ in the disposition of the parts, the male of the European seas, generally frequenting rocky places, and preying on various mollusca and crustacea. Its skin is used in commerce for the same purposes as those of other small sharks, and the fish is esteemed somewhat more edible than that of the former species. In Edwaid's figure of the young of this fish, the body is represented as barred across the back with several broad bands.

5. Squalus acudatus. Occelated or barred shark. Length about two feet and a half, colour greyish-brown, with a few scattered dusky spots; back crossed by a few dusky bands; abdomen greenish-grey; teeth numerous, small, sharp, compressed, and dilated at the base; pectoral fins rounded, and of a dusky or blackish colour, edged with white; first dorsal fin situated between the pectoral fins, and the anal fin on each side of the body. Native of the southern Pacific; observed about the coasts of New Holland during the first voyage of Sir Arch. Banks.

6. Squalus acus. Hammer-headed shark. Perhaps the most deformd of all the marine animals. Length from five to fifteen or seventeen feet; habit rather slender; body subcylindrical; head dilated on each side to a great extent; the eyes, which are very large, being placed at each extremity; mouth beneath, as in other sharks; teeth sharp, denticulated on each side, and disposed in three rows in each jaw; first dorsal fin rather large, of a somewhat falcated shape, and placed towards the upper part of the back; the second much smaller, and situated near the tail, which is rather short than long, and lobed beneath, the fin running on nearly as far as the vent; colour brown above, paler or whitish beneath. Native of the Mediterranean and Indian seas, where it is scarcely less voracious and formidable than even the white shark itself; attacking such as are accidentally exposed to its pursuit, and threatening to continue its gain in its neighbourhood. It is observed about the coasts of the southern islands, and particularly of Otaheite, where the natives, trusting to their dexterity in swimming, appear to
hold it in but little dread, since they bathe without hesitation in places known to be infested by it. This fish is said to grow about ten or fourteen young at a birth. See Plate Nat. Hist. fig. 375.

7. Squalus pristis. Sussex-mouthed shark. The snout is a large species of shark, growing to the length of fifteen feet or more: the head is slightly flattened at the top, and is produced in front into a very long, flat, straight, and slightly tapering bony snout, covered, like the rest of the animal, by minute scales; along the edges-project a great number of very strong, large, slightly flattened, and very sharp-pointed toothlike processes: the mouth, as in other sharks, is placed beneath, and is furnished on the edges of the jaws with several rows of small and somewhat blunt teeth, paving the lips, as in some of the rays. The habit of the fish is rather slender; the body convex above, and somewhat flattened beneath; the dorsal fin placed as in the squalus acanthias and several others. The whale is an inhabitant of the Mediterranean and northern seas, and was known to the ancient writers by the title of pristis. In the embryo animal the edges of the snout are observed to be bristled or pointed, but slightly attenuated by the projection of the incipient teeth or processes, which are supposed to be of very quick growth.

SQUARE. See Geometry.

Square number, the product of a number multiplied into itself.

Square, in the military art, a particular formation into which troops are thrown on critical occasions; particularly to resist the charge of cavalry.

Square, solid, is a body of foot, where both ranks and files are equal. It was formerly held in great esteem; but when the prince of Nassau introduced the hollow square, this was soon neglected.

Square, hollow, is a body of foot drawn up, with an empty space in the centre, for the colours, drums, and baggage, facing every way to resist the charge of the horse.

Square, a square which is not at right angles, but represents the figure of an oblong, whose sides are unequal. Thus as eight companies of equal numbers would form a perfect square, ten make an oblong.

Square, a square whose sides are equal and at right angles. The perfect square, in the formation of troops, seems best calculated for military movements and arrangements. Battalions, for instance, which are composed of eight companies, with one hundred rank and file in each, are equal to every species of disposition. It is upon this principle, we presume, that the French have distributed their infantry. British regiments, on the contrary, consist of ten companies, and are so composed that no square of this kind can be formed. This is manifestly a defect in our system. It is indeed remedied by the grenadier and light infantry companies being occasionally detached, or cast into separate battalions; so that the remaining companies, by being told off, are brought to eight equal parts.

Square root. See Algebra, and Arithmetick.

SQUIREL. See Scirrus.

STACHYS, a genus of plants belonging to the class of dianthae, and order of gynohermia; and in the natural system arranged under the 42d order, verticillata. The upper lip of the corolla is arched, the lower lip reflexed, the 4 long and pointed lacinia is margined. The stamine, after shedding the farina, are bent towards the sides. There are 24 species. Four only are natives of Britain; viz. 1. Sylvatica, hedge-nettle. The plant is hairy all over, erect, a yard high, and branched. The whole plant has a strong fetid smell. It grows commonly in woods and shady places, and flowers in July or August. It will dye yellow. 2. Palustris, crown's alliace. The roots are white and succulent. The stalk is branched at the bottom, and two or three feet high. The flowers are red or purple. This plant has a fetid smell and bitter taste, and is reckoned a good vulnerary. It grows on the sides of rivers and lakes, in low moist grounds, and sometimes in corn-fields.

3. Germinaca, base horehound. The stem is downy, and about two feet high. The leaves are white, downy, wrinkled, and indented. The flowers are white, purplish within, and grow in multilobed, wobby. It grows in England. 4. Arvensis, corn-stachys, petty ironwort, or all-heel. The stalk is ten or twelve inches high, square, branched, and hairy. It grows in corn-fields, and grows from June to August.

STADIUM, an ancient Greek long measure, about a furlong.

STELHENIA, a genus of plants belonging to the class of Helenea, and order of polygonia; and in the natural system arranged under the 40th order, composite. The receptacle is paleaceous, the calyx being very short; the pappus is branchy, and the seed is oval. There are 10 species: 1. Graphioides, dubia, arborescens, fruticosa, ilicifolia, corymbosa, chamaemelum, imbricata, spinosa, and laetha.

STAG. See Ceruvi.

STAG-BEETLE. See Lucanus.

STALACTITIF, ostalactagnia, stony concretions resembling icicles, in natural history, or crystalline spars formed into oblong, conical, round, or irregular bodies, composed of various minerals, and usually formed hanging in form of icicles from the roofs of grottoes, &c. See Star.

Of this class there are various species: as the hard, white stalactite; the white, shaggy stalactite; the stalagmite, a soft, shaggy, and the line stalactite. See Plate Nat. Hist. fig. 384.

STALAGMITIS, a genus of the monosee order, in the polygonia class of plants; and in the natural method ranking under the 38th order, triconce. The calyx is either quadriflory or hexaphyllous; the corolla consists of four or six petals; the receptacle is fleshy, and somewhat square-shaped; the filaments are about 30. In the hemaphrodite flower the style is short, thick, and erect; the fruit is a berry of a globular shape, unilocular, and browned with the stylum and stigma: they contain three oblong jointed triangular seeds. Of this there is only one species, viz. the cambo-giodes, a native of the East Indies and of the warmer parts of America. From this plant is obtained the gutta cambugis, or gum gamboge of the shops. See Gum resinis, and Gamboge.

Till very lately botanists were at a loss for the true nature of the plant which yields this gum. Koening, a native of Ireland, and an excellent botanist, travelled over a great part of India, and collected a great number of new plants, and among the rest the stelagmiatis. These he bequeathed to Joseph Banks.

STAMINA. See Botany.

Stamina, in the animal body, are defined to be those simple original parts, which existed first in the embryo. See Physiology.

STAMP DUTIES, a branch of the public revenue, raised by requiring that all deeds or documents, in order to be valid, shall be written on paper or parchment bearing a public mark or seal, for which a tax is paid.

Stamp-duities are said to have originated in Holland, and were introduced into England in 1671, by "an act for laying impositions on proceedings at law" these duties were very numerous, and were at first granted for nine years; they were afterwards continued for three years from 1680, when, in consequence of the unfortunate jealousies between the crown and parliament they were suffered to expire. It was not long, however, before the necessities of the government caused this mode of taxation to be again resorted to as a source more certain than any other of the taxes which then existed: an act was accordingly passed in 1694, for imposing several duties upon vellum, parchment, and paper, which may be considered as the commencement of the present stamp-office, as a particular set of commissioners were then appointed for managing the duties; and about four years after, several new duties were granted, to continue for ever, to which numerous additions have at different times been since made.

The total gross produce of the stamp-duities, in the year 1713, was 107,796l., the charges of management of which amounted to 14,206l., leaving a net produce of only 93,483l. In 1723, the net produce had increased to 130,406l.; and it seldom exceeded this amount till 1757, when some new stamp-duities were imposed, which the produce of this revenue was increased to 267,726l. in 1766 it amounted to 283,666l.; and no material additional were made till towards the conclusion of the American war. In 1785, a number of stamp-duities were imposed on various articles, although not actually collected by means of stamps, was classed with the stamp-duities. In 1784, additional duties were laid on gold and silver plate. In 1758, duties were laid on post-horses, grooms, medicines, gauzences, attorneys' licences, and pawnbrokers; all of which were deemed stamp-duities, and considerably augmented the annual amount. But a far greater increase took place in the course of the war which began in 1793, during which new stamp-duities were imposed on receipts, bills of exchange, attorneys' articles, sea-insurances, licences to wear hair-powder, house-dealers' licences, legges, hats, stage-coaches, deeds, armorial bearings, small notes, medicines, and several other articles, which soon increased this branch of the revenue to more than double its former amount; and it is a mode of taxation which is in general so difficult to evade, and with such a comparatively small expense in collecting, that there can be little doubt that it will be extended as far as possible.

Total gross produce of the stamp-duities of
STAMP DUTIES.

Great Britain, in the year ending 5th January 1800.

England and Wales £3,931,616 8 0
Scotland 266,699 4 3

£4,194,315 12 10

This amount is subject to various deductions, as, the charges of management, discounts, and other parliamentary allowances, the cost of parchment and paper for the country distributors, an allowance to the two universities on almanacs, and many incidental expenses, which reduced the actual nett produce paid into the exchequer to the following sums:

England and Wales £3,675,783 5 2
Scotland 246,170 17 2

3,918,964 2 4

The expense of collection amounted to 3l. 5s. per cent. on the gross revenue, or 3l. 9s. 6d. per cent. on the nett produce, which is considerably less than the management of the bills of the public income amounted to a few years back.

The total gross produce of the stamp-duies of Ireland for the year ending 5th January 1806, was 501,043. 9s. 10d., and the nett sum paid into the exchequer 536,533. 11s. 14d.; the expense of collection amounted to 3l. 0s. 1d. per cent. on the gross produce, or 3l. 7s. 0d. per cent. on the nett produce.

The following are the stamp-duies at present in force:

Actions, entry of, in inferior courts, 40s. and upwards, 1s. 6d. 12 Geo. c. 22.

Adjudications, appraisings, charter, resignation, clare-counter, cognizance of heirs, heritable right, confirmation, novadumas, principal and original instrument of surrender, return, saihne, and service in Scotland, 9s. 6d. 37 Geo. III. c. 90.

Administration. See Probate.

Admiralty, or cinque-ports. Any answer exhibited in these courts, 7s. 41 Geo. III. c. 86.

Any libel, allegation, deposition, or inventory, exhibited in the courts of admiralty or cinque-ports, 5s. 37 Geo. III. c. 90.

Any copy of any citation, monition, or answer, in the courts of admiralty or cinque-ports, 5s. 37 Geo. III. c. 90.

Any copy of any libel, allegation, deposition, or inventory, exhibited in the courts of admiralty or cinque-ports, 5s. 37 Geo. III. c. 90.

Any personal decree, warrant, or monition, in any court of admiralty, or the cinque-ports, or any copy thereof, 10s. 27 Geo. III. c. 90.

Any sentence given in the courts of admiralty or cinque-ports, or any attachment made out by the same, or relaxation thereof, 11s. 37 Geo. III. c. 90.

Any sentence or final decree exhibited in the courts of admiralty or cinque-ports, or any copy thereof, 4s. 37 Geo. III. c. 90.

Admission into corporations or companies, 5s. 37 Geo. III. c. 90.

Admission into any inn of chancery, 4l. 5s. 57 Geo. III. c. 90.

Admission into any of the four inns of court, 10s. 4s. 37 Geo. III. c. 90.

Admittance of fellow of college of physi-
bound to serve as a clerk, in order to his admission as a solicitor or attorney, the additional duties following, viz. For every piece of vellum, parchment, or paper, upon which shall be written any such contract, whereby any person shall become bound to serve as a clerk as aforesaid, in order to his admission as a solicitor or attorney in any of the courts at Westminster, there shall be charged a stamp-duty of 10l.

And in order to his admission as a solicitor or attorney in any of the courts of great session in Wales, or in the counties palatine of Chester, Lancaster, or Durham, or in any court of record in England, holding pleas to the amount of 40l. and not in any of the said courts at Westminster, there shall be charged a stamp-duty of 50l.

Above 30l., and not exceeding 50l., 1s. 6d. 41 Geo. III. c. 10.

Bills of exchange, promissory or other note, draft or order, where the sum amounts to 40l. and does not exceed 6l., 2s. 41 Geo. III. c. 10.

Above 6l., and not exceeding 10l., 10s. 41 Geo. III. c. 10.

Above 10l., and not exceeding 20l., 2s. 6d. 41 Geo. III. c. 10.

Bills and notes not exceeding 200l. value, and for every bill of exchange, promissory or other note, draft or order, payable on demand, or otherwise, where the sum shall exceed 200l., there shall be charged 4s. 41 Geo. III. c. 10.

Foreign bills of exchange, drawn in sets according to the custom of merchants, where the sum shall not exceed 100l., 1s. 6d. 41 Geo. III. c. 10.

Above 100l., and not exceeding 200l., 1s. 6d. 41 Geo. III. c. 10.

And exceeding 200l., 3s. 6d. 41 Geo. III. c. 10.

Bill of lading, 2s. 37 Geo. III. c. 90.

Bill of Middlesex. See Original Writ.

Bills, answers, replications, rejoinders, demurrers, interrogatories, depositions taken by commissions, and other proceedings in courts of equity, 2s. 6d. 23 Geo. III. c. 58.

Bonds (except such as are given as security for money), 15s. 41 Geo. III. c. 86.

Bonds, and bonds on wills or administrations not exceeding 20l., and bonds given by the widow of any soldier or sailor, are exempt from the duty imposed by 37 Geo. III. c. 90.

Bonds given as security for payment of money, if not above 100l., 15s. 41 Geo. III. c. 86.

Above 100l., and under 500l., 37 Geo. III. c. 90.

If of 500l. or upwards, 1l. 10s. 37 Geo. III. c. 90.

When the amount shall be of the value of 100l. or upwards, 2l. 37 Geo. III. c. 90.

When the amount shall be of the value of 200l. or upwards, 3l. 37 Geo. III. c. 90.

When the amount shall be of the value of 500l. or upwards, 5l. 37 Geo. III. c. 90.

**STAMP DUTIES.**

Briefs for collecting charitable beneficence, &c. 4l. 23 Geo. III. c. 58.

Copies writ. See Original Writ.

Cards per pack, 2s. 6d. 41 Geo. III. c. 86.

Catalogue. See Inventory.

Certificate of barrister in any of the courts of Great Britain, 3l. 37 Geo. III. c. 90.

Certificate or docket for drawback. 4s. 37 Geo. III. c. 90.

Certificate of marriage, except of seamen’s widows, 5s. 3 W. III. c. 21.

Certification. See Register, Registry, Sacrament.

Certiiorari, writ of error, or writ of appeal, except to delegates, 10s.

Certificate to kill game, 3l. 8s. See Game.

Certificate of appointment of game-keeper, 10s. 6d.

Certificate for wearing hair-powder, 1l. 1s. 41 Geo. III. c. 69.

Certificate for attorneys. See Attorney.

Certificate. See Adjudication.

Charter. See Deeds.

Chalkey-children’s indulgence. See Apprentice.

Citation or monition, libel or allegation, deposition or inventory, exhibited in any ecclesiastical court, and all copies thereof (except copies of citation or monition, for which see Answer), 2s. 6d. 23 Geo. III. c. 58.

Clare-constat. See Adjudication.

Clerk. See Admittance.

Clerks to attorneys. See Attorneys’ Clerks.

Cognition of heirs. See Adjudication.

Collation, donation, or presentation to any ecclesiastical dignity, promotion, or benefice, of the yearly value of 10l. and upwards in the King's books, 12l. 37 Geo. III. c. 90.

And to any other benediction, dignity, or spiritual or ecclesiastical promotion, 6l. 37 Geo. III. c. 90.

Commission, ecclesiastical, 5s. 10 W. III. c. 23.

Common bail in the courts at Westminster, great sessions, or county palatine, 1s. 6d. 32 Geo. II. c. 35.

Confirmation. See Adjudication.

Contract. See Deed.

Conveyance, surrender, or grants of offices, release, or other deed inrolled in any court of record, or by any custos rotulorum, or clerk of the peace, 1l. 37 Geo. III. c. 90.

Copy of deaths, 3d.

Copy of depositions in chancery, or other court of equity at Westminster, copy of any bill, answer, plea, demurrer, replication, rejoinder, interrogatories, or other proceedings whatsoever, in such courts of equity, 3d. 37 Geo. III. c. 66.

Copies of wills, 6d. 37 Geo. III. c. 90.

Any copy purporting to be a true copy, or attested to be a true copy, of any indenture, lease, or other deed, or any part thereof, for the security or use of any person, being a party to the same deed, and not having the custody of the original, or where such copy shall not be made in lieu of such original, 6s. 6d. 40 Geo. III. c. 72.

And the number of stamps required to be used for such copies of deeds is, one for every ten common law-sheets of 72 words: but if after a calculation of that number, there shall remain a number of words less in the said ten common law-sheets, no further stamp is required for the excess.

And by 39 and 40 Geo. III. c. 72, from August 1, 1800, in lieu of the stamp-duty of 6s. 8d. upon the copy of any deed, when it is for the use of another, other than any of the parties to the same deed, and who shall not have the custody of the original, or where such copy shall not be made in lieu of such original, there shall be paid a stamp-duty of 6d. on every piece of vellum or parchment, or sheet or piece of paper, on which any such copy shall be written.

And the number of stamps to be put upon every copy, is to be calculated according to the next act.

And by 39 and 40 Geo. III. c. 84, copies of indentures or other deeds, liable to the duties granted by 37 Geo. III. c. 90, may be stamped within sixty days after the date of the attestation, or payment of the duty only.

Copy of any surrender of, and admission to, any custom-right estate, not beingcopy- hold, which shall pass by surrender and admission only, and which shall not pass by deed, within England, Wales, and town of Berwick upon Tweed, 12s. 41 Geo. III. c. 86.

Copyhold estate. See Surrender.

Covenant, writ of. See Writ of Covenant.

Debenture for drawback. See Certificate.

Deed. See Indenture, written, joined, rejoinder, demurrer, or other pleading whatsoever, in any court of law at Westminster, or in any of the courts of the principality of Wales, or in any of the counties palatine of Chester, Lancaster, or Durham, and copies thereof, 3d. 32 Geo. II. c. 35.

Declaration, plea, replication, rejoinder, demurrer, or other pleading whatsoever, in any inferior court of law, and copies thereof, 2d. 10 W. III. c. 15.

Decree, personal. See Warrant.

Declinum potestas. See Original Writ.

Deeds. Any indenture (except parish-indentures), lease or deed-poll; and any charter-party, release, contract, or other obligatory instrument; or any procurement of letters of attorney; for every 15 common law-sheets, of 72 words each, 15s. 41 Geo. III. c. 86.

And moreover, by 87 Geo. III. there shall be paid upon every deed which shall be made after August 1, 1797, an additional stamp-duty of 10l. over and above all duties now payable on the vellum or paper wherein such deeds may be engraved (but this is upon the first skin only), the provisions of this act being as follows:

It shall not extend to any bond or letter of attorney, bearing date before Aug. 1, 1797.

Also it shall not extend to any indenture of apprenticeship, where a sum not exceeding 10l. shall be given; nor to any lease for not exceeding twenty-one years, the full and improved value whereof, and rent reserved thereby, shall not be more than 10l. nor to any lease for lives, or years determinable on lives, where the fine shall not exceed 20l., nor the rent reserved 40l.

But by 39 and 40 Geo. III. c. 42, the above duties shall extend to every deed, which by lease may form, or is intended to form, a part of any conveyance of lands or tenements, whereby a greater interest in the same shall be conveyed than a term of twenty-one years, whatever may be the value thereof.

Nor shall any deed be subject to the payment of any greater duty than the sum be
Grant of office or employment above 50l. a year, 6l. 12 Anne c. 9.
If above 100l. (to be calculated on the salary, fees, and perquisites), 12l. 37 G. 3. c. 90.
Habeas corpus, 5s. 5 W. 3. c. 21.
Huts. Duty on every hat of 4s. or under, 3d. 30 G. 3. c. 12.
Above 4s. and not exceeding 7s., 6d. 36 G. 3. c. 12.
Above 7s. and not exceeding 12s., one shilling. 36 G. 3. c. 12.
Above 12s. and upwards, 2s. 36 Geo. 3. c. 12.
Heritable right. See Adjudication. Horses. See Race-horses.
Indenture. See Deed.
Indentures, parish or charity. See Apprentices.
Institution, or licence ecclesiastical, in England, Wales, or Berwick upon Tweed (except licences of any ecclesiastical court or ordinary, appointing any stipendiary curate, in which the annual amount of the stipend shall be inserted), 11. 10s. 37 G. 3. c. 90.
Instrument obligatory. See Deed.
Insurance of ships, or goods from fire, 2s. per cent. 37 G. 3. c. 90.
Insurance upon any ship, goods, or merchandise, when the sum shall amount to 100l. five shillings, 41 G. 3. c. 10, and so progressively for every sum of 100l. insured. And where the sum to be insured shall not amount to 100l. a like duty of five shillings. 41 G. 3. c. 10.
And where the sum to be insured shall exceed 100l. or any progressive sum of 100l. each, by any fractional part of 100l., a like duty for each fractional part of 100l., five shillings. 41 G. 3. c. 10.
And upon every insurance where the premium shall not exceed the rate of 20s. there shall be paid where the sum shall amount to 100l. a duty of 2s. 6d. ; and so progressively for every sum of 100l. so insured. 41 G. 3. c. 10.
And where the sum to be insured shall not amount to 100l. a like duty of 2s. 6d. ; and so progressively for every sum of 100l. so insured. 41 G. 3. c. 10.
Which duties shall be payable by the assured.
This does not extend to any insurance of houses, furniture, goods, wares, merchandizes, or other property, from loss by fire, already subject to duty, nor any insurance on lives. 41 G. 3. c. 10.
Interrogatories. See Bills, copy.
Inventories or catalogue of furniture with reference to any agreement, 5s. 37 Geo. 3. c. 60.
Inventory in ecclesiastical courts. See Citation.
Judgment. See Record.
Lading. See Bill of Lading.
Lattices. See Original Writ.
Lease of land, house, &c. See Deed.
Lease for years, or other profits, not particularly charged, under the great seal, seal of exchequer, duchy or county palatine of Lancaster, or privy seal, 10l. 37 Geo. 3. c. 90.
Of the value of 20l. or under, 2s. 6d. 20 G. 3. c. 28.
Above 20l. and under 100l., five shillings. 50 G. 3. c. 58.
For 100l. and upwards, 17. 20 G. 3. c. 28.
Any other lineal descendant, or the father, or other lineal ascendant, or the husband of the deceased, to pay for a legacy or share of a personal estate.
Of the value of 20l. or under, 5s. 23 G. 3. c. 58.
Above 20l. and under 100l. ten shillings. 23 G. 3. c. 58.
For 100l. two pounds. 23 G. 3. c. 58.
For 200l. three pounds. 23 G. 3. c. 58.
For 300l. four pounds. 23 G. 3. c. 58.
And for every further sum of 100l. two pounds. 29 G. 3. c. 51.
All collateral relations, and strangers, to pay for a legacy or share of a personal estate, under the value of 20l. five shillings. 23 G. 3. c. 58.
Letter of attorney for transfer or disposal of stock, or any other purpose, fifteen shillings. 41 G. 3. c. 86.
Letters of administration. See Probate.
Letters of mart. See Mart.
Letters patent. See Grant.
Libel. See Citation.
Licence ecclesiastical. See Institution.
Licence to pawnbrokers within the bills of mortality, 10l. per annum.
Out of the bills, 5l. per annum. 25 G. 3. c. 48.
Licence for marriage, 5s. 5 W. 3. c. 21.
Licence for selling quack medicines. See Medicines.
Licence for retailing beer and ale, 2l. 2s.
Licences for spiritual liquors, sweets, and wines, to be taken out annually at the excise-office.
Licence for a mad-house, 5s.
Licence to keep lying-in hospitals, 5s.
Licence to keep lottery-office, in London, Edinburgh, or Dublin, 50l. elsewhere 10l.
Mandate. See Original Writ.
Marine Insurance. See Insurance.
Marriage licence. See Licence.
Marriage, letters of, 11. 10s. 37 G. 3. c. 90.

Middlesex, bill of. See Original.
Monition. See Citation, Warrant.
Newgate, and general circuit pardon, 4l. 23 G. 3. c. 58.
Newspapers. Every newspaper, or paper containing public news, intelligence, or occurrences, contained in half a sheet or less, 3d. 37 G. 3. c. 90.
Being larger than half a sheet, and not exceeding a whole sheet, 4d. 37 G. 3. c. 90.
Nisi prius. See Record.
Notary. See Admittance, and Attorney.
Notarial acts. Any protest or notarial act whatever, 4s. 37 G. 3. c. 90.
Note, promissory. See Bills of Exchange, Novellanus. See Adjudication.
Obligatory instrument. See Bond.
Officer of any court. See Admittance.
Order for payment of money. See Bills of Exchange.
Order in any court of Westminster, and copy, 1s. 6d. 32 G. 2. c. 35.
Original Writ (unless pro capite), subpena, bill of Middlesex, latitut, writ of capias, quo warranto, writ of debitum potestatem, every
other writ, process, or mandate, for 40s, or upwards, 5d. 3d. 35 Geo. 3. c. 30.

Pamphlets of half a sheet, or less, 1d. per sheet, for every sheet in one copy of every pamphlet not exceeding six sheets in octavo, or a less size, twelve sheets in quarto, and twenty in folio, 2s.

Pardon of corporal punishment, crime, fornication, idiocy, or money above 100l., twelve pounds. 37 Geo. 3. c. 90.
Pardon. See Newgate Pardon.

Patent, charter, or liberties. See Appen-

dice.

Passports, 2s. 37 Geo. 3. c. 90.

Patents. See Grant.

Personal decrees. See Warrant.

Plate. All gold plate made or wrought in Great Britain, except watch-cases, for oz-
troy, 10s. 37 Geo. 3. c. 90.

And for every ounce troy of all silver plate, 1s. 37 Geo. 3. c. 90.

Plea at law. See Declaration.

Plea in equity. See Copy.

Pleadings in superior courts. See Bills, Copy, Registration.

Pleadings in inferior courts. See Declaration.

Policy of assurance, on house, goods, or life, on any sum not exceeding 1000l. 6s. 25 Geo. 3. c. 58.

If above 1000l., eleven shillings. 17 Geo. 3. c. 50.

But by stat. 37 Geo. 3. c. 90. the above duties on policies, so far as the same relate to policies for insuring houses, furniture, goods, wares, merchandize, or other property, from loss by fire, are repealed from and after July 5, 1797, and from that period there shall be paid in lieu thereof:

For every policy of insurance, where the sum insured shall not amount to 1000l., the sum of 3s.

And where it shall amount to 1000l. or up-

wards, 6s. These policies are exempted from the additional ten shillings duty on deeds.

Policy of assurance upon ships. See In-

surance.

Postea. See Record.

Prelate to any ecclesiastical dignity, promotion, or benefice, of the yearly value of 10l. and upwards in the king's books; 12l. 37 Geo. 3. c. 90.

And to any other benefice, dignity, or spi-

ritual or ecclesiastical promotion, 6l. 37

 Geo. 3. c. 90.

Probate of wills, or letters of administration, of any estate above 24l. and under 100l., ten shillings.

If the estate is of the value of 100l. and

under 200l., two pounds ten shillings.

If the estate is of the value of 200l. and

under 600l., eight pounds. 37 Geo. 3. c. 90.

If the estate is of the value of 600l. and

under 1000l. fifteen pounds. 41 Geo. 3. c. 86.

If the estate is of the value of 1000l. and

under 2000l. thirty pounds. 41 Geo. 3. c. 86.

If the estate is of the value of 2000l. and

under 5000l. fifty pounds. 41 Geo. 3. c. 86.

If the estate is of the value of 5000l. and

under 10000l. seventy-five pounds. 41 Geo.

3. c. 86.

If the estate is of the value of 10000l. and

under 15000l. one hundred and ten pounds.

41 Geo. 3. c. 86.

If the estate is of the value of 15000l. and

under 20000l. one hundred and sixty

pounds. 41 Geo. 3. c. 86.

If the estate is of the value of 20000l. and

under 30000l. two hundred and ten pounds.

41 Geo. 3. c. 86.

If the estate is of the value of 30000l. and

under 40000l. three hundred and ten pounds.

41 Geo. 3. c. 86.

If the estate is of the value of 40000l. and

under 50000l. four hundred and ten pounds.

41 Geo. 3. c. 86.

If the estate is of the value of 50000l. and

under 60000l. five hundred and ten pounds.

41 Geo. 3. c. 86.

If the estate is of the value of 60000l. and

under 70000l. six hundred and ten pounds.

41 Geo. 3. c. 86.

If the estate is of the value of 70000l. and

under 80000l. seven hundred and ten pounds.

41 Geo. 3. c. 86.

If the estate is of the value of 80000l. and

under 90000l. eight hundred and ten pounds.

41 Geo. 3. c. 86.

If the estate is of the value of 90000l. and

under 100000l. nine hundred and ten pounds.

41 Geo. 3. c. 86.

If the estate is of the value of 100000l. and

upwards, 100l. 41 Geo. 3. c. 86.

And if any person shall assume any per-

sonal estate, without proving the will, or tak-

ing out letters of administration, within six

months after the death of the party, such

person shall forfeit 50l. to be recovered by

action or information. 37 Geo. 3. c. 90.

Proctor. See Admissit.

Quack medicines, by 25 Geo. 3. c. 79.

For every packet, box, bottle, pot, phial, or

other inclosure, containing drugs, herbs, pills,

water, essences, tinctures, powders, or other

preparation or composition whatsoever, used

or applied externally, or internally, as medi-

cines, or medicaments, for the prevention,

cure, or relief, of any disorder or complaint,

incident to, or in any wise affecting, the

human body, which shall be uttered or ven-

ced in Great Britain, there shall be charged a

stamp duty at the rates following, viz.

Where the contents of any such packet, box, &c. shall not exceed the price of 1s., there shall be charged a stamp duty of 1d. Above 1s. and not exceeding 2d. 6d.

4d.

10d. 1s.

20d. 2s.

30d. 3s.

3s. 6d.

5s. 10s.

And above 50s., 20s.

Quo minus. See Original Writ.

Race-horses. For every horse entered to

start or run for any plate, prize, sum of

money, or any thing whatsoever, 2l. 2s.

Receipts. By 31 Geo. 3. c. 25, the follow-

ing stamp duties shall be paid upon re-

ceipts:

For every piece of paper, &c. upon which

shall be written, &c. any receipt, discharge,
or acquittance for money, amounting to 40s.,
and not amounting to 10l., two pence.

Amounting to 10l. and not exceeding 20l. 4d.

20l. 8d.

50l. 1s.

100l. 2s.

200l. 3s.

500l.
The standard is usually a piece of silk one and a half feet square, on which are embroidered, fringed, tufted, or the prince or colored. It is fixed on a lance eight or nine feet long, and carried in the centre of the first rank of a squadron of horse, by the cornet.

**STANDARDS.** Belonging to the cavalry. Standards are posted in the following manner: The king's, with the right squadron; the second with the left; and the third with the centre.

In advancing to the front on foot, the advanced standards and their sergeants must not slacken their pace, or deviate from right to left, as the lieutenant-colonel or leading officer may happen to do; but if he is in their way, they must call to him, because they alone regulate the march.

The standards must always be brought to the parade by a troop, viz. by that which has its private parade nearest to head-quarters. They must be accompanied by as many trumpeters as can conveniently agree with that troop. Swords must be drawn, and the march sounded. The cornets parade, of course, with that troop to receive the standards. The standards are received by the cornets of the squadron, with swords drawn, officers saluting, and the march sounding by the remaining trumpeters. They must march off from head-quarters, and be lodged with the same form.

**STANDING,** in the sea-language, standing part of the ship's bottom, which is made fast to a ring at the ship's quarter. Standing part of a tackle, is the end of the rope where the block is fastened. Standing ropes, are those which do not run in any block, but are set taut or let slack, as occasion serves; as the sheet-stands, back-stands, &c.

**STANGENSPATH,** a sulphur of harytes, in bars: colour sometimes grey, red, or green; always crystalized. The crystals are frequently terminated by two- or four-sided summits, or six-sided prisms terminated by twelve-sided summits. Crystals very long and small, united in clusters. Longitudinal fracture, radiated cross fractures.

**STANNARIES,** the mines and works where tin is dug and purified, &c. in Cornwall, Devonshire, &c. There are four courts of the stannaries in Devonshire, and as many in Cornwall, and great liberties were granted them by several acts of parliament, in the time of Edward I. &c. though somewhat abridged under Edward III. and Charles I.

**STANZA.** See Poetry.

**STAPELLA,** a genus of the pentandria class of plants, the corolla whereof consists of a large, plane, single petal, quinquenced beyond the middle; the fruit consists of two oblong subulate follicles, made up of one valve, and containing one cell; the seeds are numerous, imbricated, compressed, and pappose. See Plate Nat. Hist. fig. 376. Of this very curious genus, there are 49 species; though only two species were known by Linnaeus, when he assembled his Species Plantarum, in 1732. They are all succulent plants of warm climates, and require either a dry store or a very good greenhouse. They should **not** be watered in the winter-season.

STAPES. See Anatomy.

**STAPHYLEA, BLADDER-NUT, a genus of plants, belonging to the class of pentandria, and order of trillium; and in the natural system arranged under the 23rd order, trillitae. The calyx is quinquonate. There are five petals. The capsules are three, inflated, and joined together by a longitudinal suture. The seeds are two, and are globose with a scar. There are three species. The pinna, or bladder-nut tree, is a tall shrub or tree; the leaves are palmated; the pinnae are generally five, oblong, pointed, and notched round the edges. The flowers are white, and grow in whorls on long pendulous footstalks. This plant flowers in June, and is frequent in hedges about Pontefract and in Kent. The trifoliate, or three-leaved bladder-nut is a native of Virginia.

**STAPHYLINUS,** a genus of insects of the order coleoptera; the generic character is antennæ mouthform, wing-sheaths halved, wings, covered; tail in great clusters.

**STARS,** the English term applied to the great order of the British species, is the staphylinus major of Degeer, which is more than an inch long, entirely of a deep-black colour, and when disturbed, sets up the hinder parts of its body, as if in a posture of defence; it is generally found, during the autumnal season, about sunny places, protracting, occasionally and shaggy, and within very forcible jaws. This species has often been quoted as the staphylinus maximus of Linnaeus, but it appears from late observations to be a larger, and totally distinct species from that insect. There are nearly 200 species.

**STAPLE,** primarily signifies a public place for mark, or market; as in Jewish plants, &c. are obliged to bring their goods to this place, whether of the people. Formerly the merchants of England were thus obliged to carry their wool, cloth, lead, and other staple-commodities of this order, in order to sell the same by wholesale: and these staples were appointed to be constantly kept at York, Lincoln, Newcastle upon Tyne, Northwich, Westminster, Canterbury, Chichester, Winchester, Exeter, and Bristol; in each of which a public mart was appointed to be held, and each of them had a court of the mayor of the staple, for deciding differences, held according to the law-merchant in a summary way.

The staple-commodities of this kingdom are said by some to be these: wool, leafer, wool-yards, lead, tin, butter, cheese, cloth, &c. but others allow only the first five to be staple-commodities.

**STAR, See Astronomy.**

**STARS, fading, in meteorology: meteors which dart through the sky in from of a star. See METROKS.**

Mr. John Farey (Monthly Mag. xxi. 144) has given the name SATELLITE, to the numerous masses of aerial matter, which are composed of iron and nickel principally, which are supposed by him to be revolving in all directions round this earth in elliptical orbits; and which, by passing through the highest
parts of the atmosphere, with the immense velocity peculiar to planetary motion, are rendered luminous for a short space, when in perigee, and occasion the appearance of shooting stars. They are found to move in all directions so4 so·nu·mu·lous, that M. Benzenberg, in the space of one night, observed 500 of them (Monthly Mag. xxii. 223). The same masses, when they dip deeper into the atmosphere, color the more heated, are sup·posed to appear as meteors; and, by the increasing resistance of the air in each of their revolutions, to fall at length to the earth in the fragments called meteoric stones, (see that article, where the opinions of different philosophers on the origin of these very curious substances may be seen.) In the same manner that Dr. Herschel uses the term asteroids, to express the planetary bodies revolving round the sun, which are smaller than the anciently known planets; satellitae are bodies, smaller than the moon, revolving round the earth as their centre of gravitation.

STAR. See HERALDRY.

STAR, in pyrotechny, a composition of combustible matters, which, being thrown aloft in the presence of a star, appears as a star. See PYROTECHNY.

STAR-BOARD, in the sea-language, denotes the right-hand side of a ship: thus they say, star-board the helm, or helm a star-board, when he that conds would have the men at the helm, or steering-wheel, put the helm to the right side of the ship.

STAR-FISH. See ASTERIAS.

STAR-SHOT, a gelatinous substance frequently found in fields, and supposed by the vulgar to have been produced from the meteor called a falling-star; but, in reality, is the half-digested food of herons, sea-mews, and the like birds; for these birds, when shot, have been found to digest a substance of the same kind.

STAR-STONE, asteria, in natural history, a name given to certain extraneous fossil stones, in form of short, and commonly somewhat columnar, which are composed of several joints; each resembling the figure of a radiated star, with a greater or smaller number of rays in the different species; they are usually found of about an inch in length, and of the whitish or grayish color; some of them have five angles, or rays, and others only four; and in some the angles are equidistant, while in others they are irregularly so; in some also they are short and blunt, while in others they are long, narrow, and pointed; and some have their angles so very short and obtuse, that at first sight they might be taken for enchoetrocerae. The several joints in the same specimen are usually all of the same thickness; this however is not always the case, but in some they are larger at one end, and in others at the middle, than in any other part of the body; and some species have one of the star-like band, so as to compose a species of a six-rayed kind.

STARCH. If a quantity of wheat-flour is formed into a paste, and then held under a very small stream of water, kneading continually till the water runs off from it colourless, the flour by this process is divided into two distinct constituents. A tough substance of a dirty-white colour, called glutin, remains in the hand; the water at first mildly; but soon deposits a white powder, which is known by the name of starch. A sweet-tasted mucilaginous substance remains dissolved in the water.

The starch obtained by this process is not altogether identical with that which is obtained, by means of the powdered vegetable, by distillation and filtration. In natural starch the process dissolves still more slowly. The solution resembles mucilage of gum-arabic, and still retains the peculiar colour of muriatic acid. When allowed to stand for some time, the solution gradually separates into two parts: a perfectly transparent straw-coloured liquid below; and a thick, muddy, oily, or rather mucilaginous substance, above. When water is poured in, the muriatic smell instantly disappears, and a strong smell is exhaled, precisely similar to that which is perceived in corn-mills. Ammonic occasions a slight precipitate, but too small to be examined.

Nitric acid dissolves starch more rapidly than the other two acids; it acquires a green colour, and emits nitrous gas. The solution is never complete, nor do any crystals of oxalic acid appear unless heat is applied. In this respect starch differs from gum, which yields oxalic acid with nitric acid, even at the temperature of the atmosphere. When heat is applied to the solution of starch in nitric acid, both oxalic and muriatic acid are formed, but the starch substance still remains. When separated by filtration and afterwards colulated, this substance has the appearance of a thick oil, not unlike tallow; but it dissolves readily in alcohol.

Starch is a mixture of acetic acid, and an oil having the smell and the consistency of tallow.

The alkaline dissolve starch; but their action has not been examined with care. In pure potas it swells, and assumes the appearance of a transparent jelly. In this state the solution is soluble in alcohol.

When starch is thrown upon a hot iron, it melts, blazes, froths, swells, and burns with a bright flame like sugar, emitting, at the same time, a great deal of smoke; but it does not explode, nor has it the caloromel smell which distinguishes burning sugar. When distilled, it yields water impregnated with an acid of peculiar odour, and a little tallow. The acid holds in solution gluten somewhat altered, phosphat of lime, and ammonia.

Starch was well known to the antients. Pliny informs us, that the method of obtaining it was first invented by the inhabitants of the island of Chios.

Starch has a fine white colour, and is usually concreted in longish masses; it has scarcely any smell, and very little taste. When kept dry, it continues for a long time uninjured though exposed to the air.

Starch does not dissolve in cold water, but very slowly, and forms with it a kind of emulsion. It combines with boiling water, and forms with it a thick paste. When it is allowed to cool, it assumes the form of a semi-transparent jelly; which, when dried by artificial heat, becomes brittle, and assumes an appearance not unlike that of gum. Hence it is supposed that starch, by being boiled in water, undergoes a certain degree of decomposition, which brings it nearly to the state of gum. When this paste is left exposed to damp air, it soon loses its consistency, acquires an acid taste, and its surface is covered with mould.

Starch is so far from dissolving in alcohol, even when assisted by heat, that it does not even fall to powder.

When starch is thrown into any of the mineral acids, at first no apparent change is visible; but if an attempt is made to reduce the larger pieces, while in acids, to powder, they resist it, and feel exceedingly tough and adhesive. Sulphuric acid dissolves it slowly, and at the same time a smell of sulphurous acid is emitted; and such a quantity of charcoal is evolved, that the vessel containing the mixture may be inverted without spilling any of it. Indeed, if the quantity of starch is sufficient, the mixture becomes perfectly solid. When allowed to stand for some time, the solution gradually separates into two parts: a perfectly transparent straw-coloured liquid below; and a thick, muddy, oily, or rather mucilaginous substance, above. When water is poured in, the muriatic smell instantly disappears, and a strong smell is exhaled, precisely similar to that which is perceived in corn-mills. Ammoniac occasions a slight precipitate, but too small to be examined.

Nitric acid dissolves starch more rapidly than the other two acids; it acquires a green colour, and emits nitrous gas. The solution is never complete, nor do any crystals of oxalic acid appear unless heat is applied. In this respect starch differs from gum, which yields oxalic acid with nitric acid, even at the temperature of the atmosphere. When heat is applied to the solution of starch in nitric acid, both oxalic and muriatic acid are formed, but the starch substance still remains. When separated by filtration and afterwards colulated, this substance has the appearance of a thick oil, not unlike tallow; but it dissolves readily in alcohol.

When starch is thrown upon a hot iron, it melts, blazes, froths, swells, and burns with a bright flame like sugar, emitting, at the same time, a great deal of smoke; but it does not explode, nor has it the caloromel smell which distinguishes burning sugar. When distilled, it yields water impregnated with an acid of peculiar odour, and a little tallow. The acid holds in solution gluten somewhat altered, phosphat of lime, and ammonia.
the following list of plants from the roots of which it may be extracted.

Arctium lappa,
Atropa belladonna,
Polygonum bistorta,
Hypotyl alba,
Phytolacca americana,
Spiraea filifolia,
Ranunculus bulbosus,
Scrophularia nodosa,
Sambucus ebulus,
Orchis morio,
Imperatoria ostruthum,
Hyoscyamus niger,
Rumex obtusifolius,
— aquatics,
Arun maculatum,
Orchis mascula,
Iris pseudacorus,
— tuberosa,
Orobus tuberosus,
Bunium bulbocastanum.

It is found also in the following seeds ;
Oats, Millet, Peas, Rice, Chesnut, Beans, Maize, Horse-chestnut, Acorn.

Indeed the greater number, if not the whole, of the vegetable seeds employed by man as an article of food, consists chiefly of starch. But that substance is always combined with some other which serves to disguise its properties; such as sugar, oil, extractives, &c. It is only by processes similar to those described in the beginning of this article, that it is extracted from these substances in a state of tolerable purity. The following substances, which may be considered as varieties of starch, deserve particular attention:

1. Potato starch. We are not yet in possession of a precise chemical analysis of the potato. When raw, its taste is exceedingly disagreeable, and it is said to be in some degree noxious; but it loses these qualities when boiled. The water acquires a deep brown colour, and the potato itself, when broken, appears to be composed of a congeries of fine soft cotton-like strands, to which it owes its mealy appearance. When exposed to the action of frost, it becomes soft, and acquires a very sweet taste. The nature of this change has not been examined into. When the potato is grated down to a pulp, and placed on a fine sieve, if water is poured on it, a great deal of starch passes through the meshes of the screen, and may be collected in proper vessels. When washed with water and dried, it retains a fine white colour, and possesses all the essential properties of starch. Indeed it goes much farther; a smaller quantity being sufficient to form a thick paste with water than is required of wheat-starch. It has a very perceptible crystallized appearance, and is much heavier apparently than common starch. It is not likely therefore that it could be employed with the same advantage as a hair-powder.

2. Sugar. Sugar is also extracted from the pith of several species of palm in the Moluccas, Philippines, and other East Indian islands. The pith is cut into pieces of five or six feet in length; the woody part is cut off one side, exposing the pith lying in a manner, the hollow of a canoe. Cold water is poured in, and the pith well stirred; by which means the starch is separated from the fibrous part, and passes through with the water when the whole is thrown on a sieve. That part, thus separated, is allowed to settle; the water is poured off; and when it is half dry it is granulated, by being forced through a kind of funnel. It is said to acquire its grey colour while dried in an artificial heat. This substance is employed as an article of food, and its nourishing properties are well known.

3. Salop. This substance comes from Persia; but it is said also to be manufactured in Europe. It is supposed to be the prepared roots of different species of orchis, as the morio, masuila, biolca, pyramidalis. According to Moutl, the bulbous roots of these plants are deprived of their cuticle, baked in an oven for ten or twelve minutes, which gives them their semi-transparent, and then fully dried in a moderate heat. Like sago, salop is used as a nourishing article of food.

4. Cassava is prepared from the roots of the Jatropha manihatti, an American plant. They are peeled, and subjected to a process of washing in kind of large made of rushes. The juice that is forced out is a deadly poison, and is employed by the Indians to poison their arrows; but it deposits gradually a white starch, which when properly washed is innocent. What remains in the bag consists chiefly of the same starch. It is dried in smoke, and afterwards passed through a kind of sieve. Of this substance the cassava bread is made.

5. Sowans. This very nutritious article of food is made in this country from the husk of oats, by a process not unlike that by which common starch is made. The husk of the oat (called seeds) is separated from oatmeal by the sieve. It still retains a considerable portion of parinaceous matter, which forms a very nourishing food.

STALING. See STERNUS.

STATICE, THrift, a genus of plants belonging to the class of pentandria, and order of pentagonia; and in the natural system ranging under the forty-eighth order, aggregate. The calyx is imphomphyllous, entire, folded, and scarious. There are five petals, and the inferior seed-case or ovule is of three, nine species; three of these are British plants.

1. The armoria, thrift, or sea gilly-flower, has a simple naked stem about six inches high. The radical leaves are like grass. The flowers are terminal, pale red, with a round head, and not very large. This plant flowers in July or August, and grows in meadows near the sea. 2. Limonium, sea-lavender. The stem is naked, branched, and about a foot high. 3. Rosibranda, sea-lavender. The stem is prostrate, and terminated by a panicle of flowers. This species is also found on the sea-coast of South Britain.

STATICS, that branch of mathematics which considers the motion of bodies arising from gravity. See Motion.

Statics then is the doctrine, or theory, of motion, considered merely as arising from the weight of bodies; in which sense it is distinguished from dynamics; or the application of the principles of mechanics to machines, &c. Though, it must be owned, that statics and mechanics are frequently confounded. See Mechanics.

For the laws and principles of mechanics, see the articles Gravity, Gravitation.

STATIONARY. See Astronomy.

STATISTICS, a word lately introduced to express a view or survey of any kingdom, country, or parish.

A grand and extensive work of this kind was undertaken in Scotland in the year 1799 by sir John Sinclair, whose patriotic exertions in favour of his country will be gratefully remembered by posterity. The great object of it is to give an accurate view of the state of the country, its agriculture, its manufactures, and its commerce; the means of improvement, of which they are respectively capable; the amount of the population of a state; and the causes of increase or decrease: the manner in which the territory of a country is possessed and cultivated; the nature and amount of the various productions of the soil; the value of the personal wealth or stock of the inhabitants, and how it can be augmented; the diseases to which the people are subject, their causes and their cure: the occupations of the people; where they are entitled to encouragement, and where they ought to be repressed; the condition of the poor, the best means of maintaining them, and of giving them employment; the state of schools, and other institutions, formed for purposes of public utility; the state of the villages and towns, and the regulations best calculated for their police and good government; the state of the manners, the morals, and the religious principles of the people, and the means by which their temporal and eternal interests can best be promoted.

STATUARY, a branch of sculpture, said to be the invention of Dacalus, amidst other productions of ingenious talents: others assert him to have been only the improver of an art known long before his time, and that he was the first who endeavoured to give the appearance of motion and action to figures.

The Punicans are said to have been the first who erected statues in honour of their gods; but, if we believe the accounts generally given of the Punican worship, the religious custom of that nation did not exhibit human forms, but merely pointed stones or other symbolical expressions of their divinities.

STATUES, are figures, representing living or deceased creatures, of whatever species, real or imaginary; and carved, cast, modelled, or moulded, in full relieve, insulated on every part.

Statues are formed with the chisel, of several materials, such as marble, stone, &c.: they are carved in wood; or cast in plaster of Paris, or other matter of the same nature; they are also cast in several metals, as lead, brass, silver and gold.

Statues are divided into Colossal, or considerably exceeding the dimensions of nature; as, for instance, the celebrated statue of Apollo, at Rhodos.

Allegorical, or such as, under human or other symbolical forms, represent subjects of a different kind, as Time, Ocean, Winds, or qualities of an intellectual nature, as Mercy, Justice, &c.

Statues of deities, demi-gods, and heroes were, among the ancients, generally represented somewhat larger than life.

Monumental, either representing the person, the virtues, or the actions of the deceased.
Equestrian, generally of some illustrious person on horseback.

Pedestrian; or on foot.

The most celebrated statues are those of the Egyptians, Grecians, and Romans. Of the Egyptian statues, which have been said under the article sculpture. See SCULPTURE. Of the Grecian and Roman we propose to add some important particulars.

**Statues.** The denomination of ancient statues is applicable to all antique statues, found either in India, Egypt, &c. but is especially given, in preference, to the statues wrought by the ancient Greek and Roman sculptors. The works of the Grecians are considered as the most perfect examples of sculpture. Their statues are eminently admirable for the various beauty of their forms, for characteristic expression and grace. See SCULPTURE.

The Grecian statues of men are generally naked. The Roman are clothed agreeably to the manner of the country, and are distinguished into

1. Palliata (stature), those of emperors with long robes over their armour.
2. Loricae, those of soldiers with cuirasses.
3. Thoricata, those with coats of armour.
4. Togata, those of magistrates with the toga, or robe worn in office.
5. Tribune, those of senators and augurs.
6. Tunicata, those clothed with a plain tunic.
7. Statilia, those of women with long trains.

The antique statues are most particularly remarkable for their systematic representation of the human form. As the principle most apparent in their system is that of proportions, we shall give, first, an account of their general proportions to which they chiefly adhered, and next, an accurate measurement of the various parts of the body, taken at Rome, from some of their most celebrated original statues.

It is to be observed, however, that although the inferior antique possesses little other merit than that of proportion, the excellence of the finer works of Greece is of a much more comprehensive description.

**Proportions of the antique statues.**

Proportion is the basis of beauty, and there can be no beauty without it; on the contrary, proportion may exist where there is little beauty. Experience teaches us, that knowledge is distinct from taste; and proportion, therefore, which is founded on knowledge, may be strictly observed in any figure, and yet the figure have no pretensions to beauty. The antiquists considering ideal beauty as the most perfect, have frequently employed it in preference to the beauty of nature.

It is probable that the Grecian, as well as the Egyptian artists, determined the great and small proportions by fixed rules; that they established a positive measure for the dimensions of length, breadth, and circumference. This supposition alone can enable us to account for the great conformity which we meet with in antique statues. Winckelmann thinks that the foot was the measure which they used in all their great dimensions, and that it was by the length of it that they regulated the measure of their figures by giving to them six times that length. This, in fact, is the length which Vitruvius assigns, L. 3, cap. 1. That celebrated architect thinks the foot is a more determinate measure than the head or the face, the parts from which modern painters and sculptors often take their proportions. This proportion of the foot to the body, which has appeared strange and incomprehensible to the learned Huetius, has been entirely rejected by Perrault, is, however, founded upon experience. After measuring with great care a vast number of figures, Winckelmann found this proportion not only in Egyptian statues, but also in those of Greece. This fact may be determined by an inspection of those statues, the feet of which are perfect; and one may be more fully convinced of it by examining some figures of the Greek divinities, in which the artists have made some parts beyond their natural dimensions. In the Apollo Belvedere, which is a little more than seven heads high, the foot is three Roman inches longer than the head. The head of the Venus de Medici is very small, and the height of the statue is seven heads and a half; the foot is three inches and a half longer than the head, or precisely the sixth part of the length of the whole statue.

Other writers are of opinion, that the following rules form a principal part of the system of Grecian sculpture:

The body consists of three parts, as well as the members. The three parts must bear a certain proportion to one another, as well as to one another. In a well formed man, the head and body must be proportioned to the thighs, the legs, and the feet. The arms also consist of three parts. These three parts must bear a certain proportion to the whole body, but as well as to one another. In a well formed man, the head and body must be proportioned to the thighs, the legs, and the feet, in the same manner as the thighs are proportioned to the legs and the feet, or the arms to the hands. The face also consists of three parts, that is, three times the length of the nose; but the head is not four times the length of the nose, as some writers have asserted. From the face begins to the crown of the head, are only three-fourths of the length of the nose, or that part is to the nose as 9 to 12.

**Measurements taken at Rome from original antique statues.**

**Hercules (Farnese).**

Length of the face as nearly as can be found, 11 inches and a half.

From the pit between the clavicles to the bottom of the belly, 2 feet 10 inches.

From the point of the (right) os ilium to the top of the patella, the same, viz. 2 feet 10 inches.

From the top of the patella to the sole of the right foot, 2 feet 10 inches and a half.

From the top of the head as nearly as can be guessed, to the bottom of the belly, 4 feet 2 inches and a half.

From the bottom of the belly to the sole of the foot, 5 feet 2 inches and three-fourths.

**Colossal Commodus (of the Capitol).**

Length of the face from the top of the forehead to the bottom of the chin, as nearly as can be guessed (the hair being down on the forehead), 3 feet 2 inches.

Flora (Farnese).

From the pit between the clavicles to the bottom of the belly; from the point of the (right) os ilium to the centre of the patella; and from the centre of the patella to the sole of the foot, exactly equal.

From the pit between the clavicles to the right nipple, 14 inches and a half.

From the pit of the belly to the sole of the foot, 5 feet 8 inches.

Length of the leg from the centre of the patella to the sole of the foot, 3 feet 1 inch.

The measurements of the four following female statues, have for their rule the real length of their respective faces, divided into three parts, and those parts subdivided into twelve minutes. See Plate No. 9, (entitled Antiquae Statuae.)

Venus de Medicis.

From the bottom of the right ear to the pit between the clavicles, 3 parts.

From the bottom of the left ditto to the said pit, 2 parts 9 minutes.

From the said pit to the bottom of the sternum, as near as can be found, 3 parts 6 minutes and one-third.

From the said pit to the bottom of the belly, as near as can be found, 9 parts 1 minute and three-fourths.

From the point of the (right) os ilium, as near as can be found, to the centre of the patella, 9 parts 4 minutes and one-third.

From the said pit to the right pap, 3 parts 5 minutes; to the left ditto, 3 parts 6 minutes.

From the centre of the right patella to the sole of the foot, 9 parts 8 minutes and one-third.

From the centre of the said patella to the sole of the foot, 9 parts.

Length of the right foot from the heel to the joint of the great toe, 4 parts 9 minutes and two-thirds.

Length of the left ditto, 4 parts 8 minutes.

Breadth of the face from ear to ear, 2 parts 3 minutes.

From the right ear to the tip of the nose, 2 parts 1 minute and one-third.

Thickness of the neck, measured with the face in front, 1 part 11 minutes and a half.

Distance from pap to pap, 3 parts 11 minutes.

From point to point of the ileum, as near as can be found, 4 parts and half a minute.

Breadth of the shoulder, just below the heads of the humeri, measured obliquely, viz. parallel with the shoulders, 7 parts 9 minutes and a half.

Breadth of the breast, from the point where the pectoral and deltoïd muscles join, 5 parts 5 minutes and one-fourth.

Narrowest part of the body, a little above the navel, 4 parts 9 minutes and a half.

Breadth of the hips, measured upon the ilium under the oblique, descends 6 parts 4 minutes and a half.

Thickest part of the right thigh measured as near as can be across the centre of the rectus, 3 parts 6 minutes.

Thickness of the said knee across the centre of the patella, 1 part 1 minute.

Thickest part of the calf of the said leg, 2 parts 2 minutes and a half.

Small ditto, just above the ankle, 1 part 2 minutes and three-fourths.
Thicknes of the said ancle from centre to centre of each bone, 1 part 5 minutes and one-fourth.

Thicknes of the left knee measured across the patella, 2 parts.

Thicknes of the calf of the left leg, 2 parts 2 minutes.

Small ditto, just above the ancle, 1 part 2 minutes.

From centre to centre of the ancle bones of the left leg, 1 part 4 minutes and one-fourth.

Breadth of the left foot upon the joints, at the roots of the toes, 1 part 9 minutes.

Length from the head of the detoiso to the tip of the left elbow, 7 parts; right ditto, 7 parts 2 minutes.

Length of the lower right arm from the tip of the elbow to the centre of the wrist, 4 parts 11 minutes.

Length of the left ditto, ditto, 5 parts 1 minute, and two-thirds.

Thickest part of the right arm above the elbow, 1 part 11 minutes.

Thickness of the lower arm, measured with the back of the hand in front, 1 part 8 minutes and one-half minute.

Ditto of the said wrist from bone to bone, 1 part three-fourths of a minute.

Thickest part of the left arm, measured in front, 1 part 9 minutes and a half.

Thickness of the lower arm ditto, measured like the former, 1 part 7 minutes and one-fourth.

Thickness of the said wrist from bone to bone, 1 part and one-half minute.

From the middle of the wrist to the root of the middle finger, 1 part 10 minutes.

Length of the middle finger, 1 part 8 minutes and one-fourth.

Breadth of the hand across the joints at the roots of the fingers, 1 part 4 minutes and a half.

Ditto of the body from the most prominent part of the breast bone to ditto of the shoulder behind, measuring and observing the curve of the figure, 4 parts 2 minutes and one-fourth.

Narrowest part of the body, measured from the hollow above the navel, to the most prominent part of the sacro-umbilical, observing the curve of the figure, 3 parts 10 minutes.

Distance from the navel to the bottom of the belly, 4 parts and one-half minute.

Length from the point of the left os ilium, as near as can be found, to the most prominent part of the glutaeus below, 5 parts.

Distance from ditto to ditto of the right side, 4 parts 7 minutes.

Thickest part of the right thigh in profile, from the centre of the rectus, 3 parts 7 minutes.

Thicknes of the said knee in profile from the centre of the patella, 2 parts 4 minutes and two-thirds.

Ditto of the calf of the right leg, in ditto, 2 parts 3 minutes; smallest part ditto, 1 part 5 minutes and one-fourth.

Thicknes of the left thigh from just under the glutaeus to the rectus above in profile, 3 parts 8 minutes.

Ditto of the left knee, in profile, from the centre of the patella, 2 parts 4 minutes.

Thicknes of the said leg above, 2 parts 4 minutes; ditto of ditto at the small, 1 part 5 minutes and one-fourth.

Total length of the figure, allowing 4 parts for the head, and measuring down the centre of the figure, 31 parts 11 minutes and a half.

Flora Festita, or dropt.

From the bottom of the ear to the pit between the clavicles, 2 parts 8 minutes and a half.

Length of the neck from where it joins the bottom of the chin to the said pit, 1 part 4 minutes.

From the said pit to the right nipple, 3 parts 2 minutes and a half; left ditto, 3 parts 2 minutes.

From the pit between the clavicles to the bottom of the belly as near as can be guessed, 11 parts 10 minutes.

From the elbow to the pit, 3 parts 7 minutes and a half.

From the roots of the hair on the forehead to the sole of the foot, 10 faces, or 30 parts 8 minutes.

Length of the leg bent from the top of the patella to the sole of the foot, 9 parts 3 minutes.

Cleopatra of the Belvidere.

From the bottom of the chin to the pit between the clavicles, 1 part 7 minutes.

From the tip of the right ear to the said pit, 3 parts 5 minutes.

From the said pit to the left nipple, 3 parts 4 minutes; right ditto 3 parts.

Total length of the body, as it lies, from the said pit to the bottom of the belly, 9 parts 4 minutes.

From the bottom of the belly to the middle of the patella, as near as can be guessed, 9 parts 2 minutes.

From the middle of the patella to the instep, 9 parts 5 minutes.

From the instep to the sole of the foot within, 1 part 9 minutes.

Length of the left arm underneath, from where it joins to the pectoral, to the point of the elbow, 5 parts 9 minutes.

From the same elbow to the joint of the wrist, 5 parts 6 minutes and a half.

Thickness of the same arm above the elbow, measured from underneath, to about where the deltoid muscle is inserted, 2 parts 5 minutes and one-fourth.

Thickest part of the same arm below the elbow, 2 parts 3 minutes.

Breadth of the wrist from bone to bone, 1 part 5 minutes.

Thickness of ditto from the centre below to the centre above, 9 minutes.

Breadth of the body across the breasts as near as can be measured, 7 parts 3 minutes.

Ditto of ditto, as near, &c. across the belly just below the navel from hip to hip, 7 parts 10 minutes and a half.

Breadth from nippel to nippel, 4 parts 3 minutes.

Thickness of the upper thighs, measured over and across about the middle, 3 parts 10 minutes and a half.

Ditto knee ditto, across the middle of the patella, 2 parts 9 minutes and a half.

Calf of the leg, ditto, 2 parts 10 minutes and a half.

Ankle ditto from bone to bone, 1 part 7 minutes and a half.

Total length of the figure, allowing 1 part above the roots of the hair upon the forehead, and measuring down the middle of the figure, down the centre of the upper thigh and to the sole of that foot, as near as can be known, somewhat less than 30 parts.

Breadth of the right foot from the joint at the root of the great toe to the joint on the other side at the root of the little toe, 2 parts 3 minutes.

Length of the great toe from the centre of the joint, 1 part 7 minutes.

Beautiful daughter of Niohe.

From the chin next the throat to the pit between the clavicles, 1 part 10 minutes.

From the tip of the left ear to ditto, 3 parts 1 minute and a half.

From the tip of the right to ditto, 2 parts 7 minutes and three-fourths.

From the said pit to the left nippel, 2 parts 10 minutes.

From ditto to the right nippel, 3 parts 2 minutes.

From nippel to nippel, as near as can be guessed, 4 parts.

Length of the body from the pit between the clavicles to the bottom of the belly, 9 parts.

From the point of the ilium (guessed) to the centre of the patella, 8 parts 5 minutes.

From the centre of the patella to the sole of the foot, 8 parts 8 minutes and a half.

The measurements of the following male figures, have for their rule, the real length of their respective heads, divided into four equal portions, called fourths, and those fourths subdivided into twelve equal parts.

See the Plate.

Apollon.

From the bottom of the chin next the throat to the pit between the clavicles 1 fourth 9 parts.

From the pit between the clavicles to the pit at the bottom of the breast, 2 fourths 6 parts and one-half.

From ditto to the pit of the right breast, 3 fourths 6 parts and one-half.

From ditto to the pat of the left breast, 2 fourths 8 parts; from pat to pat 1 head.

Whole length of the body from the pit between the clavicles to the bottom of the belly, about 3 faces.

From point to point of the os ilium next the belly, 1 head wanting 2 parts.

From the point of the right os ilium to the middle of the patella, 3 faces.

From the left ditto to the upper edge of the patella, 3 faces.

From the middle of the right patella to the sole of the foot, 3 faces.

Breadth of the face from ear to ear, 9 fourths 3 parts.

Thickness of the neck immediately under the ears, 2 fourths and half a part.

Thickness of the body in a line drawn across the paps, almost 6 fourths.

Narrowest part of the body from the lowest rib to rib, 5 fourths.

Breadth of the body where it joins the thigh, 6 fourths 8 parts.

Umost thickness of the thigh, 3 fourths, 1 part 2 fourths.

Thickness of the knee across the centre of the right patella, 2 fourths nearly.

Thickest part of the calf of the leg in front, 2 fourths 2 parts.

Thickest part of the right ankle, above the ankle bone, 2.4 parts and two-thirds.
Thinnest part of the right instep, below the ankle, 1 fourth 2 parts.
Thickest part of the ankle from the centre to the centre of each bone, 1 fourth 4 parts.
Thickest part of the foot, across the joint at the roots of the toes, 1 fourth 10 parts.
Utmost length of the right foot, 4 fourths 9 parts and a half.
Utmost length of the left arm from the top of the shoulder to the tip of the elbow, 6 fourths 4 parts.
From the same elbow to the joint of the wrist, nearly, 5 fourths.
From the same joint to the root of the middle finger, 1 fourth 9 parts and a half.
Thickest part of the left arm, across the insertion of the deltoid, 1 fourth 11 parts.
Thickest part of the dito below the elbow, 1 fourth 7 parts and a half.
Thickest part of the wrist, measured from above, 1 fourth and two-thirds of a part.
From the elbow to the centre of the right arm, below where the latissimus dorsi passes, as near as can be guessed, 5 fourths and a half.
Thickest part of that arm, measured in front across the biceps, 1 fourth 10 parts.
Thickest part of the body, measured in profile on the left side, from the pit between the breasts to the back in a horizontal direction, 3 fourths.
Thinnest part of the body on the same side, measured just above the navel, 3 fourths 9 parts.
Thickest part of the thigh in profile, measured in a horizontal direction, from the root of the penis to the glutaeus, 4 fourths 6 parts.
Thinnest part, just above the knee, 2 fourths 2 parts and three-fourths.
Thickest part of the right knee, 2 fourths and 3 parts.
Thickest part of the calf of the leg, 2 fourths 3 parts and a half.
Thinnest part of the same leg, just above the instep, 1 fourth 6 parts and one-fourth.
From the centre of the inner ankle to the bottom of the heel, 1 fourth 6 parts.
From the centre of the outer dito to dito, 1 fourth 2 parts.

Apollo Belvedere.
From the tip of the right ear to the pit between the clavicles, 2 fourths 10 parts.
From the bottom of the left ear to the same pit, 3 fourths and half a part.
From the pit between the clavicles to the centre of the pit at the bottom of the sternum, 2 fourths 11 parts and a half.
From the pit between the clavicles to the bottom of the belly, 2 fourths 9 parts and a half.
From the point of the right ilium to the centre of the patella, 8 fourths 11 parts and a half.
From the point of the left dito to the centre of the patella, 9 fourths 3 parts and three-fourths.
Length of the right leg from the centre of the patella to the sole of the foot, 9 fourths 6 parts.

Statues.
From the pit between the clavicles to the right pap, 3 fourths 4 parts.
From ditto to the left pap, 3 fourths 5 parts and one-fourth.
Distance across from pap to pap, 4 fourths 9 parts and three-fourths.
Breath of the body across the paps, 6 fourths and half a part.
Narrowest part of the body, measured a little above the navel, 5 fourths 1 part and one-fourth.
Breath of the hips, measured upon the ilium just under the oblique, descends, 5 fourths 2 parts and a half.
Breath from point to point of the ilium, 3 fourths 10 parts and a half.
Thickest part of the right thigh, measured in front across the head of the rectus, 2 fourths 11 parts.
Thickest part of the left dito, 2 fourths 11 parts and a half.
Thickness of the right knee across the centre of the patella, 1 fourth 10 parts.
Thickness of the left dito, 1 fourth 9 parts and a half.
Thickness of the clavicles, 1 fourth 8 parts.
Thickness of the calves of the legs, taken in front, 2 fourths 1 part and a half.
Small of the right leg just above the ankle, 1 fourth 2 parts and a half.
Ditto of the left leg dito, 1 fourth 1 part.
From centre to centre of the ankle bones of each leg, 1 fourth 4 parts.
Thickness of the instep on the foot immediately under the right ankle, 1 fourth and half a part.
Length of the right foot from the point of the heel to the point of the great toe, 4 fourths 3 parts and one-fourth.
Ditto of the left, 4 fourths 5 parts.
Breath of the right foot on the joints at the roots of the toes, 1 fourth 6 parts and two-thirds.
Length of the right arm from the head of the deltoid to the tip of the elbow, 6 fourths 3 parts.
From the tip of the elbow to the centre of the wrist bone, 4 fourths 10 parts and two-thirds.
Thickness of the right arm, taken in front, 1 fourth 6 parts and one-third.
Ditto in profile about the middle, 2 fourths and one-third of a part.
Thickest part of the right thigh in profile as near as can be taken, 3 fourths 5 parts and three-fourths.
Thickness of the right knee dito to the centre of the patella, 2 fourths and two-thirds of a part.
Thickness of the calf of the leg in profile, 2 fourths 2 parts.
Thickness of the small of the leg in profile, 1 fourth 5 parts and a fourth.
Total length of the Apollo, including four parts to the head, and measuring down the centre of the body, 32 fourths 2 parts.

Borghese Faun.
From the bottom of the right ear to the pit between the clavicles, 4 fourths.
Total length of the body from the pit between the clavicles to the bottom of the belly, 8 fourths 3 parts.
Length of the right thigh from the point of the ilium to the centre of the patella, 9 fourths 2 parts and one-third.
Length of the right leg from the centre of the

Sleeping Faun (Barberini).
Distance from the right ear to the pit between the clavicles, 3 fourths.
Length of the neck from the bottom of the chin to the pit between the clavicles, 1 fourth 9 parts and a half.
From the said pit to the pit at the bottom of the sternum, 2 fourths 6 parts and a half.
Total length of the body from the said pit to the bottom of the belly, 7 fourths 1 part.
Length of the right thigh in its restored state
From the point of the ilium to the top of the patella, 9 fourths 7 parts.
From the top of the patella to the sole of the foot, 8 fourths 10 parts and a half.
Breadth of the face from ear to ear, as near as can be measured, 2 fourths 5 parts and a half.
Breadth of the neck from side to side, 2 fourths 1 part.
Ditto of the breast from pop to pop, 3 fourths 3 parts and a half.
Breadth from point to point of each ilium, 3 fourths 11 parts and one-third.
From the pit at the bottom of the sternum to the navel, 2 fourths 6 parts and a half.
Utmost thickness of the thigh across the head of the rectus, 3 fourths 2 parts and a third.
Utmost thickness of the body across the paps, 6 fourths 4 parts.
Narrowest part of ditto at the bottom of the ribs, 5 fourths 3 parts and a half.
Length of the arm over the head, from the centre of the head of the humerus, as near as can be found, to the tip of the elbow, 6 fourths.
Length of that arm below, from the tip of the elbow to the centre of the wrist, 5 fourths and one-third of a part.
Utmost thickness of the body from the most prominent part of the breast to the trapezius behind below the shoulder, measured in a right line, 4 fourths 8 parts and a half.
From the hollow part of the rectus before, a little above the navel, to the sacro-lumbaris behind, measured in a right line, 4 fourths 7 parts and a half.
Thickness of the arm from the centre of the biceps to the triceps behind, 2 fourths and half a part.
N.B. The tip of the right elbow; all the left arm below the deltoid; all the right thigh and leg, with so much of the left thigh as is between the broadest part of the rectus and its insertion at the knee, (all of which is antique, together with a part of the sartorius, gastrocnemius, and peronei without the leg) and all the other part of that leg and foot, have been restored by Burnini.

Laocoön.

From the bottom of the right ear to the pit between the clavicles, 3 fourths 3 parts and one-third.
From ditto of the left ear to the said pit, 2 fourths 10 parts and a half.
From the said pit to the centre of the pit at the bottom of the sternum, 3 fourths 4 parts.
From the said ditto to the top of the navel in a right line, 3 fourths 4 parts.
From the tip of the navel to the privities, 2 fourths 8 parts.
From the point of the ilium to the centre of the patella of the left thigh, 9 fourths 8 parts.
From the point ditto of the right thigh to the centre of the patella, 9 fourths 2 parts.
From the centre of the left patella to the instep or annular ligament, 8 fourths 2 parts.
From the said point at the instep to the bottom of the heel ditto, 1 fourth 1 part.

From the pit between the clavicles to either pop, 3 fourths 2 parts and three-fourths.
Length of the left arm from the head of the deltoid to the tip of the elbow, 6 fourths 7 parts and a quarter.
From the tip of the said elbow to the centre of the joint of the wrist, 5 fourths 1 part and a half.
Length of the back of the hand from the centre of the wrist to the joint of the middle finger, 1 fourth 4 parts and a third.
Length of the first joint of the middle finger, 1 fourth 1 part.
Thickness of the neck in front, about the middle, 2 fourths 3 parts.
Distance across from pop to pop, 4 fourths 2 parts and two-thirds.
Breadth of the body measured horizontally across the nipples, 6 fourths 5 parts and a half.
Breadth of ditto measured horizontally at the narrowest part across the bottom of the ribs, 5 fourths.
Breadth across on the ilium immediately under the obliquus descendens, 5 fourths 4 parts.
Thickness of the left thigh measured across the centre of the rectus, 3 fourths 3 parts and one-third.
Thickness of the knee measured across the centre of the patella, 1 fourth 11 parts and a half.
Thickness of the right ditto, 1 fourth 11 parts and a half.
Thickness of the calf of either leg, 2 fourths 2 parts.
Thickness of the smallest part just above the ankle, 1 fourth and half a part.
From centre to centre of the left ankle bone, 1 fourth 5 parts; right, ditto.
Narrowest part of the instep just under the ankles, 1 fourth and two-thirds of a part.
Breadth of the foot from the centre of the joint at the root of the great toe to ditto of the little one, 1 fourth 11 parts and one-third.
Thickest part of the left arm measured across the centre of the biceps, 2 fourths 2 parts and one-third.
Ditto of the said arm measured on the supinator just below the elbow, 1 fourth 9 parts and a half.
Breadth across the wrist measured from the centre of the joint, 1 fourth 3 parts.
Breadth of the hand measured upon the joint at the roots of the fingers, 1 fourth 10 parts and two-thirds.
Thickness of the body in profile measured from the centre of the pectoral muscle to the most prominent part of the trapezius behind, 4 fourths 9 parts.
Narrowest part of the body in profile measured just above the navel, 3 fourths 6 parts and a half.
Thickness of the knee from the head of the gastrocnemius to the centre of the patella, 2 fourths 6 parts and a half.
Thickest part of the calf of the right leg in profile, 2 fourths 4 parts.
Thickest part of the small of the left leg in profile, 1 fourth 6 parts.
Length of the left foot from the heel to the top of the great toe, 4 fourths 8 parts.
Total length of the figure of the Laocoön, allowing 4 fourths for the head, and measuring from the bottom of the chin to the pit between the clavicles, and from thence, following with the utmost exactness the line of the centre of the body, then measuring on the centre of the left thigh (after having found the point by laying a rule across from the bottom of the belly parallel with the two points of the ilium), and so down the centre of the patella, and upon the leg to the sole of the foot, 34 fourths.

Laocoön's elder son...

From the bottom of the left ear to the pit between the clavicles, 2 fourths 11 parts.
From ditto of the right ear to the said pitt, 2 fourths 6 parts and a half.
From the said pit to the centre of the pit at the bottom of the sternum, 2 fourths 7 parts and a half.
From the centre of the said pit to the centre of the navel, 2 fourths 7 parts.
From the centre of the navel to the privities, 2 fourths 7 parts.

From the point of the right ilium to the centre of the patella, 8 fourths 7 parts and a half.
From the centre of the patella to the instep, 8 fourths 1 part.
From the said instep to the bottom of the heel, 1 fourth 8 parts and one-third.
From the centre between the clavicles to either pop, 2 fourths 10 parts and three-fourths.
Distance across from pop to pop, 4 fourths 5 parts and one-third.
Ditto from point to point of the ilium, 3 fourths 4 parts.

Length of the left arm measured from the head of the humerus, as near as can be guessed, to the tip of the elbow, 5 fourths 8 parts and two-thirds.

Thickest part of the body measured across the paps, 6 fourths 4 parts.

Narrowest part of ditto measured across the bottom of the ribs, 5 fourths 3 parts.

Breadth of the body measured upon the ilium immediately under the obliquus descendentis, 5 fourths 7 parts and a half.

Thickest part of the right thigh in front, across the centre of the rectus, 2 fourths 7 parts and a half.

Thickness of the knee across the centre of the patella, 1 fourth 11 parts and one-third.

Thickest part of the calf of the leg, 2 fourths 3 parts.

Thickness of the small of ditto just above the ankle, 1 fourth 1 part and a half.

Thickest part of the ankle from the centre of each bone, 1 fourth 4 parts and a quarter.

Breadthest of the right foot across the joints at the roots of the toes, 1 fourth 8 parts.

Thickness of the upper arm in profile across the middle of the biceps, 1 fourth 11 parts and a half.

Ditto of the lower arm just below the elbow; ditto, 1 fourth 0 parts.

Thickness of the right thigh in profile, 3 fourths 4 parts and three-fourths.

Ditto of the knee ditto from the centre of the patella, 2 fourths 6 parts.

Thickness of the calf of the leg ditto, 2 fourths 4 parts.
From the tip of the right ear to the pit between the clavicles, 2 fourths 8 parts.
From the said pit to the pit at the bottom of the sternum, 2 fourths 8 parts.
From ditto to the right pap, 2 fourths 8 parts.
From the pit between the clavicles to the bottom of the belly, 8 fourths.
From the said part to the pit at the bottom of the sternum, 2 fourths 8 parts.
From ditto to the right pap, 2 fourths 8 parts.

Younger son of Laocoon.

From the tip of the right ear to the pit between the clavicles, 2 fourths 8 parts.
From the said pit to the pit at the bottom of the sternum, 2 fourths 8 parts.
From ditto to the right pap, 2 fourths 8 parts.
From the pit between the clavicles to the bottom of the belly, 8 fourths.

Thickening of the body in profile from the most prominent part of the pectoral muscle to the trapezius behind, 4 fourths 3 parts and a half.

Narrowest part of ditto measured a little above the navel, 3 fourths 3 parts.
Total length of the figure measured down the centre, allowing 4 fourths to the head, and following the same method as with the foregoing statue of the father, 30 fourths exact.

Antinous.

From the bottom of the left ear to the pit between the clavicles, 2 fourths 9 parts.

From the pit between the clavicles to the pit at the bottom of the breast, 2 fourths 10 parts and two-thirds.
From ditto to either pap, 3 fourths 4 parts.

Germanicus.

From the bottom of the chin to the pit between the clavicles, 1 fourth and two-thirds of a part.
From the tip of each ear to the said pit, 2 fourths 7 parts and a third.
From the pit between the clavicles to the pit at the bottom of the breast, 3 fourths 3 parts and a half.
From pap to pap, 4 fourths 10 parts.

From point to point of the ilium, 3 fourths 10 parts and one-third.

Breadth of the face from ear to ear, 2 fourths 3 parts and two-thirds.

Thickness of the neck about the middle, 2 fourths 1 part and a half.

Breadth of the temple of the shoulders from deltoid to deltoid, 8 fourths 9 parts and a half.

Narrowest part of the body at the bottom of the ribs, 5 fourths 1 part.

Breadth measured on the ilium immediately under the obliques descendens, 5 fourths 4 parts and a half.

Ditto of the thickest part of the left thigh across the rectus, 3 fourths 1 part.

Ditto of the right ditto, 2 fourths 11 parts.

Thickness of the left knee across the centre of the patella, 1 fourth 11 parts.

Ditto of the right ditto, 2 fourths.

Thickness of the right leg at the thickest part, 2 fourths 3 parts.
From centre to centre of the ankle bones, 1 fourth 4 parts and one-third.

The foot is not antique.

Length from the head of the deltoid to the centre of the right elbow, 6 fourths 9 parts and a half.

From ditto to the centre of the wrist bone, 4 fourths 6 parts and a half.

From the centre of the wrist bone to the joint of the little finger, 1 fourth 6 parts and a half.

Breadth of the body in profile from the shoulder to the most prominent breast, 4 fourths 10 parts and a half.

Narrowest part of the body ditto at the bottom of the ribs, 3 fourths 4 parts and three-fourths.

Thickness of the most prominent part of the gluteus to the head of the rectus, 4 fourths 1 part.

Thickest part of the thigh about the middle of the rectus, 3 fourths 5 parts.

Thickest part of the knee ditto, 2 fourths 3 parts.

Thickness of the arm ditto about the middle of the breasts, 2 fourths 2 parts and one-third.

Melenor.

From the left ear to the pit between the clavicles, 2 fourths 10 parts and a half.
From the right ditto, 2 fourths 9 parts and a half.

From the pit between the clavicles to the bottom of the belly, 9 fourths.

From ditto to the centre of the pit at the bottom of the sternum, 3 fourths.

From ditto to the pap on the right breast, 1 fourth 1 part and a half.
Length of the right thigh from the point of the ilium to the top of the patella, 9 fourths.
From the top of the patella to the sole of the foot ditto, 9 fourths 3 parts.
Distance from pap to pap, 4 fourths 2 parts.

Broadest part of the body measured across the paps, 8 fourths 9 parts and two-thirds.

Narrowest part of ditto measured at the bottom of the ribs, 5 fourths 5 parts.

Breadth of the hips measured on the ilium immediately under the obliques descendens, 5 fourths 7 parts and a half.

Thickest part of the thigh measured in front, 2 fourths 10 parts and one-third.

Thickness of the right knee across the centre of the patella, 1 fourth 10 parts and a half.

Thickest part of the calf of the leg, 2 fourths 1 part and one-third.

Thickness of the small of the leg ditto just above the ankle, 1 fourth.

From centre to centre of each ankle bone, 1 fourth 5 parts.

Length of the right foot from the heel to the tip of the toe, 4 fourths 4 parts.

Broadest part of the said foot from the joint at the root of the great toe to ditto of the little toe, 1 fourth 9 parts.

Breadth of the face from ear to ear in front, 2 fourths 3 parts.

Ditto of the neck ditto in front about the middle, 2 fourths and half a part.

Length of the arm from the head of the deltoid to the tip of the elbow, 6 fourths 11 parts and one-third.

Thickest part of the arm measured in front across the biceps, 1 fourth 7 parts and a half.

Thickness of the arm in profile from the biceps to the triceps behind, 2 fourths 1 part and three-fourths.

Ditto of the body measured from the most prominent part of the pectoral muscle to the trapezius, 4 fourths 6 parts and one-third.

Narrowest part of the body in profile ditto, just above the navel, 3 fourths 7 parts and one-third.

Thickest part of the thigh on the rectus just under the gluteus, 4 fourths 4 parts and one-third.

Thickness of the knee in profile on the centre of the patella, 2 fourths 2 parts.

Thickest part of the calf of the leg in profile, 2 fourths 2 parts and three-fourths.

Smallest of ditto, 1 fourth 4 parts.

Breadth from point to point of the ilium, 3 fourths 9 parts and two-thirds.

Total length of the figure, allowing 4 fourths to the head, and measuring down the line of the centre of the body, then laying a line parallel with the points of the ilium, and measuring down the middle of the thigh to the sole of the right foot, 31 fourths 4 parts.
From ear to ear measured across the face, 2
fourths 3 parts and a half.
Thickest thickness of the neck in front, 2
fourths 1 part.
From the pit between the clavicles to the back of the shoulder measured horizontally, 4
fourths 4 parts.

From the great trochanter of the left thigh to the most prominent part of the right thigh measured horizontally, 5
fourths 9 parts and one-half.

Thickest part of the right thigh measured horizontally across the middle of the rectus, 3
fourths.

Ditto of the left ditto continuing the same horizontal line, 2
fourths 8 parts.

Right knee across the centre of the patella, 1
fourth 10 parts; left ditto, ditto.
Thickest part of the calf of the right leg, 2
fourths 1 part and a half; ditto of the left, 2
fourths and a third of a part.

Thickest part of the ankle of the left leg, 1
fourth 1 part and a fourth; right, ditto.

Thickest part of the ankles from the centre of bone to bone, 1
fourth 2 parts and three-fourths.

Thickest part of the right foot from the joint at the root of the great toe, 1
fourth 9 parts.

Ditto, ditto of the left foot, 1
fourth 8 parts.

From the head of the deltoid muscle to the tip of the right elbow measured within, in
front, 6
fourths 2 parts.

From the tip of the elbow to the centre of the ulna at the right wrist, 4
fourths 4 parts, and a half.

From the head of the deltoid to the left elbow, 5
fourths 9 parts and a half.
Thickest part of the body from the most prominent part of the pectoral muscle before, to the most prominent part of the scapula, taken horizontally in profile, 4
fourths 10 parts and a half.

Narrowest part of the body measured just above the navel, 3
fourths 6 parts.

From the hollow of the thigh at the head of the rectus before, to the most prominent part of the gluteus behind, 4
fourths 2 parts.

Thickest part of the right thigh measured below the gluteus, 3
fourths 5 parts and a half.

Thickest part of the right knee in profile from the centre of the patella to the hollow below, 2
fourths 2 parts and a half.

Thickest part of the calf of the right leg in profile, 2
fourths 2 parts; ditto above the ankle, 1
fourth 5 parts.

Length of the right foot, 4
fourths 4 parts and three-fourths.

Thickest part of the right arm from the biceps to the triceps, 1
fourth 11 parts and a half.

Broadest part of the wrist from bone to bone, 1
fourth 2 parts.

Thickest part of the neck taken in profile, 2
fourths.

For the greatest number of the so much admired Grecian statues lay, for a long series of years, buried under the ruins of Rome.

The following is a brief account of the
Discovery of several of the most celebrated statues, or groups, in various parts of Rome.  

I. The equestrian statue of M. Aurelius was found on the Caelian hill, near the pre-

ent church of St. John Lateran, in the por-
ticate of Sixtus IV. (1471 to 1484) who placed it in that place. About the year 1540 it was removed to the capitol, under the di-
rection of Michel Angelo.

II. The torso of Hercules in the Vatican, was found in the Campo de’ Fiori, in the time of Julius II.

III. The group of the Laocoön was discovered in the vineyard of Guiltieri, near the baths of Titus, by Felix de Fredis, in 1512, as recorded on his tomb in the church of Ara Coeli.

IV. In the reign of Leo X: the Antinous, or Mercury according to Visconti, was found on the Esquiline hill, near the church of St. Martin.

V. Leo was likewise successful in recovering from oblivion the Venus called de Medicis. It was found in the portico of Octavia, built by Augustus, near the Theatre of Marcellus, in the modern Pesciera. Removed to the gallery at Florence by Cosmo III. in 1676.

VI. The colossal Pompym of the Spada palace, was found during the pontificate of Leo XIII. (1559 to 1554) near the church of St. Lorenzo in Damaso.

VII. The Hercules, and the group of Dirce, Zethus, and Amphion, called "Il toro," now at Naples, were dug up in the baths of Caracalla, and placed in the Farnese palace, about the middle of the sixteenth century.

VIII. The Apollo Belvidere, and the Gla-
diator of the Villa Borghese, were taken from under the ruins of the palace and gardens of the Antium, 40 miles from Rome, when the Casino was made there by cardinal Borghese, during the reign of Paul V. (1605 to 1612).

IX. Soon afterward, the sleeping Faun, now in the Barberini palace, was found near the mausoleum of Hadrian.

X. The Mirmillo Expirans, or Dying Gladi-
diator of the capitol, was dug up in the gardens of Salust, on the Ficinan hill, now in the Villa Borghese, was purchased by Benedict the 14th, of cardinal Lodovisi.

XI. The small Harpocrates and the Venus of the Capitol were found at Tivoli in the same reign.

 XII. The Meleager, once in the Picchini collection, now in the Vatican, was found near the church of St. Bibiena.

STATUTE, in its general sense, signifies a law, ordinance, decree, &c. Statute, in our laws and customs, more immediately signifies an act of parliament made by the three estates of the realm; and such statutes are either public, of which the courts at West-
minster must take notice, without pleading a new cause; or they are special and private, which last may be pleaded. It is held, that a public
statute, made in affirmation of the common law, extends to all times after the making thereof, although it mentions only a re-
medy for the present; and where a thing is given or granted by statute, all necessary in-
cidents are at the same time granted with it.

The most natural exposition of a statute is, to construe one part by another of the same statute, because that best expresses the intent of the legislature. In general, it is, or ought to be expounded in suppression of the mischief, and for the advancement of the remedy desired by any statute, yet so that
to innocent person may suffer or receive any damage thereby. It is held, that statutes will continue in force, though the records of them are destroyed. &c. But if a statute is against reason, or impossible to be performed, the same is void of its own nature.

When a statute is repealed, all acts done under it, while it was in force, are good; but if it is declared null, all these are void. Jenk. 333, pl. 6.

Here a statute, before perpetual, is continued by an affirmant statute, for a time, this does not amount to a repeal of it at the end of that time. Lord Raym. 397.

Where two acts contradictory to each other, are passed in the same session, the latter only shall take effect. 6 Mod. 287.

STATUTE MERCHANT, is a bond of record, acknowledged before one of the clerks of the statute merchant, and lord mayor of the city of London, or two merchants of the said city, for that purpose assigned, or before the mayor or warden of the town, or other discreet men for that purpose appointed. This recognizance is to be entered on a roll, which must be double, one part to remain with the mayor, and the other with a clerk, who shall write with his own hand a bill obligatory, to which a seal of the king for that purpose appointed, shall be annexed, together with the seal of the
debtor. 2 Inst. Abr. 331.

The design of this security was to promote and encourage trade, by providing a sure and speedy remedy for merchant-servers, as well as natives, to recover their debts at the day assigned for payment.

But though the statute-merchant seems first to be introduced, and wholly calculated, for the ease and benefit of merchants, as the name itself imports; yet they were not long engrossed by them: for other men finding from their own observation, that they have much of the same nature with judgments in Westminster-hall, but obtained with less trouble and expense, out of regard to their own interest and quiet, easily fell into this way of contracting, and by degrees it came into the nature of a custom, and was improved into an absolute assurance, as we find it at this day. Winch. 83. See Insur-

ANCE.

STATUTE STAPLE, is a bond of record, acknowledged before the mayor of the staple, in the presence of all or one of the constables. But now statute staple, as well as statute merchant, are in a great measure become obsolete.

STATUTES, of Statutes sessions, other-
wise called petit sessions, are a meeting in every hundred, of all the shires in England, where by custom they have been used, whereunto the constables and others, both house-
holders and servants, repair for the debating of differences between masters and servants, the rating of servants’ wages, and bestowing such people in service, as being fit to serve, either refuse to seek or get masters. Stat. 5 Eliz. c. 5.

STAVES, in music, the five horizontal and parallel lines on and between which the notes are placed.

Guido, the great improver of the modern music, is said by some to have first used the stave; but others give an earlier date to its introduction. Kircher affirms, that in the Jesuit’s library at Messina he found a Greek manuscript of hymns more than seven hun-
dred years old, in which some of the music
was written on slaves of eight lines, marked at the beginning with eight Greek letters; the notes, or rather points, were on the lines, but no use was made of the spaces. This, however, at most, only deprives Guido of the original invention of the stave, and still leaves him the credit of its great improvement by reducing it to five lines, and employing both lines and spaces.

**STAUROLITE, in mineralogy.** This stone has been found at Andreasberg in the Harz. It is crystallized, and the form of its crystals has led mineralogists to give to the name of cross-stone. Its crystals are two-sided, flattened prisms, terminated by four-sided pyramids, intersecting each other at right angles; the plane of intersection passing longitudinally through the prism. Sometimes these prisms occur solitary. Primitiv form, an octahedron with isosceles triangular faces. The faces of the crystals striated longitudinally.

The texture is foliated. Its lustre glassy. Brittle. Specific gravity 2.33 to 2.36. Colour milk-white. When heated slowly, it loses 0.15 or 0.16 parts of its weight, and falls into powder. It effervesces with borax and microcrystalline of charcoal, and is esteemed to a greasy opaque mass. With soda it melts into a frothy white enamel. When its powder is thrown on a hot coal, it emits a greensh-yellow light.

A specimen analysed by Westrum was composed of:

- 44 silica
- 20 alumina
- 20 barytes
- 16 water

100.

Klaproth found the same ingredients, and nearly in the same proportions.

A variety of staurolite has been found only once, which has the following properties:

Its lustre is pearly. Its transparency 2.50. Colour a brownish-grey. With soda it melts into a purplish and yellowish frothy enamel. It is composed, according to Westrum, of:

- 47.5 silica
- 12.0 alumina
- 20.0 barytes
- 16.0 water
- 4.5 oxides of iron and manganese

100.0.

**STEEL, a carburet of iron, or that metal combined with a small portion of carbon. See Iron.**

**STEERING, on board a ship, that part of the ship next below the quarter-deck, before the bulkhead of the great cabin, where the steersman stands in most ships of war. See the next article.**

**STEERING, in navigation, the directing of a vessel from one place to another by means of the helm and rudder. He is held the best steersman who causes the least motion in putting the helm over to and from it, and who keeps the ship from making yaws, that is, from running in and out. There are three methods of steering:

1. By any mark on the land, so as to keep the ship even by it.
2. By the compass, which is kept fixed on the ship's head, and is reduced to a rhumb or point of the compass as best leads to port.
3. To steer as one is bidden or conned, which, in a great ship, is the duty of him that is taking his turn at the helm.**

**STELLARIA, stellwort, a genus of plants belonging to the class of dicotandria, and order of trignia, and in the natural system arranged under the 220rd order, caryophyllae. The calyx is pentaphyllous and spreading. The petals are red, pink, or white, the stamens are divided into two segments. The capsule is oval, unilocular, and polyspernum. There are 17 species; three of these are British plants. 1. Nemorum, broad-leaved stichwort, is an evergreen, with green leaves, common in woods and hedges. 3. Graminea, less stichwort. The stem is near a foot high. It is frequent in dry pastures.**

**STELLATE. See Botany.**

**STELLERIA, German groundsel, a genus of plants belonging to the class of octandria, and order of monogynia, and in the natural system arranged under the 313rd order, vergeculce. There is no calyx; the corolla is quadridenata. The stamens are very short; there is only one seed, which is black. The species are two in number, passerina and chamaejasme.**

**STEM. See Botany.**

**STEM, of a ship, that main piece of timber which comes bending from the keel below, where it is scarfed, as they call it, that is, pieced in; and rises compassing right before the forecastle. This stem it which guides the rake of the ship, and all the weight of the planks are fixed into it. This, in the section of a first-rate ship, is called the main stem. See Ship-building.**

**STEMMATA, in the history of insects, are three smooth hemispheric dots, placed generally on the top of the head, as in most of the hystenopterous and other classes.**

**STENODILS, a genus of plants belonging to the class of dicotyledon, and order of angiosperma, and in the natural system ranging under the 27th class, and 26th order, of flora. The calyx is quinquartate; there are five stamens; each of the filaments is bilb, and they have two antherae. The capsule is bicollar. There are four species, herbs of the East and West Indies.**

**STENOGRAPHY. The art of stenography, or short-hand writing, was known and practised by most of the ancient civilized nations. The Egyptians, who were distinguished for learning at an early period, at first expressed their words by a delineation of figures called hieroglyphics. A more concise mode of writing seems to have been afterward introduced, in which only a part of the symbol or picture was drawn. This answered the purpose of short-hand in some degree. After them the Hebrews, the Greeks, and the Romans, adopted different methods of abbreviating their words and sentences, suited to their respective languages. The initials, the letter were reduced for whole words; and various combinations of these sometimes formed a sentence. Arbitrary marks were likewise employed to determine the meaning, and to assist legibility; and it seems probable that the compiler, and every author of antiquity, had some peculiar method of abbreviation, calculated to facilitate expression of his own sentiments, and intelligible only to himself. All the were probably, that some might by these means take down the heads of a discourse or oration; but few, very few, it is, presumed, could have followed a speaker through all the meanders of rhetoric, and noted with precision every syllable, as it dropped from his mouth, in a manner legible even to themselves. To arrive at perfection in the art was reserved for more modern times, and is still an acquisition by no means, general. In every language of Europe, till about the close of the 16th century, the Roman plan of abbreviating (viz. substituting the initials or radicals, with the help of arbitrary characters) was the standard employed. Till then no regular alphabet had been invented expressly for stenography, when an English gentleman of the name of Willis invented and published one; since which we have had a multitude of others by Mason, Gurney, Byron, Palmer, &c. &c. The following is extracted from Dr. Mavor's treatise on the art, which has met with general approbation.**
STENOGRAPHY.

Hewho mdu us mbe ental, grt, nd nmnpnt.
It is ur dry, as rut bags, to sry, te, nd obly h.
A nnt tdl wdd, knd, nd b skunk in.
I wk, wh th wll hst to pss evry bdy.
I w ftm frm any knxs wth n nmn who
nd n rd fr hntt; nd b w w w w w.
N w w w w w w w w.

The characters expressing nine of the consonants are all perfectly distinct from one another; eight only remain which are needful, viz., f, v, d, b, p, g, r, w, and s, to find characters for which we must have recourse to mixed curves and lines. The characters which we have adopted are the simplest in nature after those already applied, admit of the easiest joining, and tend to preserve linearity and beauty in the writing. It must be observed that we have no character for c when it has a hard sound, as in conte; or soft, as in city; for it naturally takes the sound of k or ñ, which in all cases will be sufficient to supply its place.

Rlikewise is represented by the same character as 1; only with this difference, r is written with such an ascending stroke and l with a descending; which is always to be distinguished from the form of the following character; but in a few monosyllables, where r is the only consonant in the word, and consequently stands alone, it is to be made as is shown in the alphabet for distinguishing it from s.

Z, as it is a letter seldom employed in the English language, and only a coarser and harsher expression of s, must be supplied by s whenever it occurs; as for Zedekiah, write Sdekkiah, &c.

The prepositions and terminations in this scheme are so simple, that the greatest benefit may be reaped from them, and very little trouble required to attain them; as the incipient letter or the incipient consonant of all the prepositions, and of several of the terminations, is used to express the whole. But although in the Plate sufficient specimens are given of the manner of their application, that the learner of less ingenuity or more slow perception may have every assistance, we have subjoined the following directions:

1. The preposition is always to be written without joining, yet so near as plainly to show what word it belongs to; and the best way is to observe the same order as if the whole was to be connected.

2. A preposition, though the same letters that constitute it may be met with in the middle or end of a word, is never to be used, because it would expose it to obscurity.

3. Observe that the preposition omni is expressed by the vowel o in its proper position; and for anti, am, ante, by the vowel o, which is the radical part of the word which will easily distinguish from being only simple vowels.

The first rule for the prepositions is (allowing such exceptions as may be seen in the Plate) to be observed for the terminations; and also the second mutatis mutandis, except that whenever s, sus, sus, cions, tions, and ces, occur, they are to be expressed a distinguished in the fourth rule for the consonants, whether in the beginning, middle, or end of words.

4. The terminative character for tio, cion, cion, cion, cion, cion, is to be expressed by a small vertical line placed over the next or penultimate letter when next or penultimate is the right; and the plurals, tions, cions, cions, cions, cions, cions, tions, tions, tions, by a dot on the same side.

**Vol. II.**
The mode of stereotype printing is, first to set up a page, for instance, in the common way, and when it is rendered perfectly correct, a cast is taken from it, and in this cast the metal plate is poured. For the sake of economy, this method of printing has lately been brought into practice by Earl Stanhope, who seems to have overcome all difficulties, and to have rendered the art as perfect as can be expected. His lordship intends to make the invention public.

STERLING, a term frequent in British commerce. A pound, shilling, or penny, signifying as much as a pound, shilling, or penny, of lawful money of Great Britain, as settled by authority.

STERNE, the term, a genus of birds of the order anseres. The marks of this genus are a straight, slender, pointed bill, linear nostril, a slender and sharp tongue, very long wings, a small back toe, and a forked tail. There are 23 species, according to Dr. Latham; the caspia, cayama, surinamensis, fuligiceps, africana, stolba, philippina, simplex, milvina, boissi, striata, vittata, gallica, albonitida, hierodula, pannonica, chrysa, alba, mutica, sinensis, australis, metopoliscus, fisipes, nigra, and obscura. Three of these only are found in Great Britain; the hierodula, minuta, and fisipes. See Plate Nat. Hist. fig. 377.

1. The hirundo, common tern, or great sea-swallow, weighs four ounces one quarter; the length is fourteen inches; the breadth thirty; the bill and feet are of a fine crimson; the breast of the crown, and a small part of the head, black; the throat, and whole underside of the body, white; the upper part, and the coverts of the wings, a fine pale-grey. This is a very common species, frequent on sea-coasts, the mouths of lakes and rivers during the summer, but is most common in the neighbourhood of the sea. It is found also in various parts of Europe and Asia, according to the season; in the summer, as far as Greenland and Spitzbergen, migrating in turn to the South of Austria and Greece. It lays three or four eggs about the month of June, of a dull olive-colour.

These are laid among the grass or moss.

The young are hatched in July, and quit the nest very soon after. They are carefully fed by their parents, and fly in about six weeks. This bird appears to have all the actions on the water which the swallow has on land, skimming on the surface, and seizing on every insect which comes in its way; besides which, the moment it spies a fish in the water, it darts into that element, and seizing its prey, arises as quickly to the place from which it dipp't.

2. The sterna, or smaller sea-swallow, weighs only two ounces five grains; the length is eight inches and a half, the breadth nineteen and a half. The bill is yellow, tip with black; the forehead and cheeks white; from the eyes to the bill is a black line; the top of the head and back part black; the breast and under side of the body cloathed with feathers so closely set together, and of such an exquisite rich gloss and so fine a white, that no satin can be compared to it. These two species are very delicate, and seem unable to bear the inclemency of our shores during winter, for we observe that they quit their breeding-place at the approach of it, and do not return till spring. The manner, haunts, and food, of this species, are the same with those of the former; but they are far less numerous.

3. The fissipes, or black tern, is of a middle size between the first and second species. The usual length is ten inches; the breadth 24; the weight two ounces and a half. The head, neck, breast, and belly, as far as the vent, are black; beyond is white; the male has a white spot under his chin; the back and wings are of a deep ash-colour; the tail is short and forked; the exterior feather on each side is white; the outside, an ashy colour, the legs and feet of a dusky red. These bear frequent fresh waters, breed on their banks, and lay three small eggs of a deep olive-colour, much spotted with black. They are found during spring and summer in vast numbers in the main of Lincolnshire, make an incessant noise, and feed on flies as well as water-insects and small fishes. Birds of this species are seen very remote from land.

STERDIPHY, a genus of fishes of the order apodes. The head oblate, teeth very minute; gill membrane broad; body compressed, without apparent scales; breast, carinate folded; belly pellicled. There is but a single species, that inhabits America, viz. diaplanus.

STERNUM. See Anatomy.

STEWARD, a man appointed in a place or estate, and always signifies a principal officer within his jurisdiction. The greatest of these is the lord-high-steward of England; and that office being very great, of late he has not usually been appointed for any length of time, but only for the dispatch of some special business, as the trial of some nobleman in cases of treason, &c. after which his commission expires.

STICKLEBACK. See Gasterosteus.

STICKS, feet, in printing, slips of wood that lie between the foot of the page and the chase, to which they are wedged fast by the quins, to keep the form firm, in conjunction with the side-sticks, which are placed at the side, the pages being fixed in the same manner by means of quoins.

STIGMA, in entomology, a spot or anastomosis in the middle of the wings of insects near the anterior margin, conspicuous in the hymenopterous tribes.

STIGMATA, in natural history, the apertures in different parts of the bodies of insects or crustaceans, to receive the reproductive organs, or air-vessels, and serving for the office of respiration.

STIGMATIZING, among the antients, was inflicted upon slaves as a punishment, but more frequently as a mark to know them by; in which case it was done by applying a red-hot iron marked with certain letters to
their foreheads, till a fair impression was made, and then pouring ink into their furrows, that the inscription might be the more conspicuous. Stigmata, among some nations, are the marks of a distinguishing mark of honour and notoriety.

STILACO, a genus of plants belonging to the class of gymnospermae, and order of triandria. There is one female. The calyx is monopetalous, and almost three-lobed. There is no corolla, and the berry is globular. There are three species, the pinaster, encoides, and cernus, all foreign plants.

STILBE, in botany, a genus of plants belonging to the class of polygamous, and order of dicotyledons. The exterior calyx of the hermaphroditic flower is triphyllous; the interior is quinquedentate and carpogynous. The corolla is funnel-shaped and quincuncial. There are four stamina and there is one seed in the interior calyx calyptra. The female flower is similar, but has no interior calyx nor fruit. There are three species, the pinaster, encoides, and cernus, all foreign plants.

STILBITES. This stone was first formed into a distinct species by Mr. Hawy. Formerly it was considered as a variety of zoila.

The primitive form of its crystals is a rectangular prism, whose bases are rectangles. It crystallizes sometimes in dodecahedrons, consisting of a four-sided prism with hexagonal faces, terminated by four-sided summits, whose faces are oblique parallelograms; sometimes in six-sided prisms, two of whose solid angles are wanting, and a small triangular face in their place. Its texture is foliated. The laminae are easily separated from each other, and are somewhat flexible. Lustre: Pearl. Hapness inferior to that of zoila, which scratches stilbite. Brittleness: Specific gravity 2.360. Colour: Pearl white, or grey. Powder bright white, sometimes with a shade of red. This powder, when exposed to the air, cakes and adheres as if it had absorbed water. It causes syrup of violets to assume a green colour. It is somewhat decomposed in a porous crucible, it swells up and assumes the colour and semitransparency of baked porcelain. By this process it loses 0.185 of its weight. Before the blowpipe it froths like borax, and is dissipated into an opaque white, coloured enamel. Does not gelatinise in acids. Not electric by heat.

According to the analysis of Vanquelin, it is composed of

It occurs most commonly in lava, but is found also in primitive rocks.

STILL. See Distillation.

STILLINGIA, a genus of plants belonging to the class of monocotyledonae, and the order of monocotyledones. The male calyx is spherical and multinerved. The corolla is tubular, and erose or grained. The female calyx is unilocular and inferior. The corolla is superior. The style is trifid, and the capsule three-grained. There is only one species, the sylvatica.

STING, an apparatus in the body of certain insects, in form of a little spear, serving them as a weapon of offence. The sting of a bee or wasp is a curious piece of mechanism: it is hollow, as shown in fig. 2; there is of there a bag full of sharp penetrating juice, which in stinging is injected into the flesh, through the tube; within the tube, Mr. Derham has observed, there lie two sharp small hard spines. In the sting of a wasp he told eight beads on the sides of each spine, somewhat like the beads of fish-books. One of these spines in the sting, or shesh, lies with its point a little before the other, to be ready, as should seem, to be dropped into the flesh, which once fixed by means of its foremost bead, the other then strikes too, and so they alternately pierce deeper and deeper, their heads taking more and more hold in the flesh; after which the second or sting follows to convey the poison into the wound, which, that it may pierce the better, is drawn into a point with a small slit below that point for the two spines to come out at. By means of these beads it is, that the animal is thereby forced to lower itself behind it, when disturbed, because it can have no time to withdraw the spines into the scabbard.

STIPAS, feather-grass, a genus of plants belonging to the class of triandria, and order of graminées. There are two species, STILAGO, STILBE, under the 4th order, graminées. The calyx is bivalved. The exterior valve of the corolla is terminated by an awn; the base is jointed. There are 14 species. Of these, the common species is the feather-grass. The beards are feathered. The plant rises to the height of ten inches, grows on mountains, and flowers in July or August.

STIPULA. See Botany.

STIRRUP of a ship, a piece of timber put upon a ship's keel, when some of her keel happens to be broken off, and they cannot come conveniently to put or fit in a new piece; then they patch in a piece of timber, and bind it on with an iron, which goes under the ship's keel, and comes up on each side of the ship, where it is nailed strongly with spikes, and this they call a stirrup.

The company offering a strong reward for finding the murderers, stock-jobbing was carried to an enormous extent, which ended in the ruin of thousands. When the mischief was done, a bill was brought into parliament to prevent this "infamous practice," though the experience of the past might have been considered as the best security that it would never again be carried to the same height. The act passed was soon found ineffectual, in consequence of which another was brought in by Sir John Barnard in 1732, which being rejected, it was brought forward again in 1734, and passed. It is stat. 7. and 8. Geo. c. 8. and declares all contracts and agreements residing in the encouragement to stock or securities, to be null and void, and the money paid thereon shall be restored, or it may be recovered by action commenced thereon within six months, with double costs. All contracts and agreements whatsoever,
made or entered into by buying, selling, assigning, or transferring any public or joint stock, or other public securities whatsoever, or of any part, share, or interest therein, whereof the person or persons contracting or agreeing shall be the same; or upon whose behalf the contract or agreement shall be made, to sell, assign, and transfer the same, shall not, at the time of making such contract or agreement, be actually possessed of, or entitled unto, in his, her, or their own name or names, or in trust for their use, are null and void to all intents and purposes whatsoever; and all and every person whatsoever contracting or agreeing, or on whose behalf, or with whose consent any contract or agreement shall be made to sell, assign, or transfer any public or joint stock or stocks, or other public securities, whereof such person or persons shall not, at the time of making such contract or agreement, be actually possessed of, or entitled unto, in their own name, or in the names of trustees to their use, shall forfeit 500l.

Notwithstanding these prohibitions and penalties, the practice of stock-jobbing has continued, and greatly increased; and though it is attended with many evil consequences, it is doubtful whether, if possible, it would be politic to prevent it, while the public debt continues of such enormous amount; as the current value of the public funds would frequently be greatly depressed if it was not supported by the transactions of those who make a regular trade of dealing therein.

STOCKS, the public funds of the nation instituted for the purpose of paying the interest of the loan. See Loan.

STOCKS, among ship-carpenters, a frame of timber, and great posts made ashore, to build pinneys, ketches, boats, and such small craft, and sometimes small frigates. Hence we say, a ship is on the stocks when she is a building.

STOCKS, a wooden machine to put the legs of offenders in, for the securing of disorderly persons, and by the way of punishment in cases of serious breach. And it is said, that every vill within the precinct of a town is inducible for not having a pair of stocks, and shall forfeit 50l.

STOEBE, a genus of the syngeossy polyantha segregata class of plants; the corolla of the flowers is equal; the proper one is monopetalous and funnel-shaped; the limb is quinquefid and patulous; there is no pericarpium; the seed, which is contained in the cup, is solitary, oblong, and crowned with a long hairy pap. There are nine species.

STOKESIA, a genus of the syngeossy polyantha equatilis class and order of plants. The corollis in the ray are funnul-form, longer, irregular; down four-bristled; recept. naked. There is one species, a herb of South Carolina.

STOLE, gown of the, the eldest gentleman of his majesty's bed-chamber, whose office and honour it is to present and put on his majesty's first garment, or shirt, every morning, and to order the things in the chamber.

STOLEN GOODS. To help people to stolen goods for reward without apprehending the felon. 4 G. I. c. 11.

Persons having or receiving lead, iron, copper, brass, bell-metal, or solder, knowing the same to have been stolen, shall be transported.

29 G. II. c. 30.

STOMACH. See Anatomy.

STOMATEUS, a genus of fishes of the order apodes; the generic character is, head compressed; teeth in the jaws and palate; body oval, broad, slippery, tail forked. There are three species, viz. the farlota, body beautifully barred, each in its proper sheath; feeders, two, short, setaceous, of five articulations; antennæ setaceous. There are 16 species.

STONE, calcinus humanus. See Calculi, and Medicine.

STONES from the atmosphere. See Meteorology.

STONES. See Mineralogy.

STONES and EARTH, analysis of. The only substances which enter into the composition of the simple stones, as far at least as analysis has discovered, are the six earths, silica, alumina, zirconia, gluhia, lime, and magnesia; and the oxides of iron, manganese, nickel, chromium, and copper. Seldom more than four or five of these substances are found combined together in the same stone; we shall suppose, however, in order to prevent unnecessary repitions, that they are all contained in the mineral which we are going to analyse.

Let 100 or 200 grains of the stone to be analysed, previously reduced to a fine powder, be mixed with three times its weight of pure potassa and a little water, and exposed in a silver crucible to a strong heat. The heat should at first be applied slowly, and the mixture should be constantly stirred to prevent the potassa from swelling and throwing any part out of the crucible. When the whole water is evaporated, the mixture should be kept for half an hour or three quarters of a pint.

If the matter in the crucible melts completely, and appears as liquid as water, we may be certain that the stone which we are analysing consists chiefly of silica; if it remains opaque, and of the consistence of paste, the other earths are more abundant; if it remains in the form of a powder, alumina is the prevalent earth. If the matter in the crucible is of a dark or brownish red colour, it contains oxide of iron; if it is greenish, manganese is present; if it is yellowish green, it contains chromium.

When the crucible has been taken from the fire and wiped on the outside, it is to be placed in a mortar, and ground to powder with water. This water is to be renewed, from time to time, till all the matter is detached from the crucible. The water dissolves a part of the combination of the alkali with the silica of the stone; and if a sufficient quantity was used, it would dissolve the whole of that combination.

Muriatic acid is now to be poured in till the whole of the matter is dissolved. At first a facky precipitate appears, because the acid combines with the alkali which kept it in solution; when the effervescence takes place, owing to the decomposition of some carbonat of potassa formed during the fusion. At the same time the facky precipitate is dissolved; as is also that part of the matter which is dissolved in a concretion formed in the water, had remained at the bottom of the dish in the form of a powder. This powder, if it consists only of silica and alumina, dissolves without effervescence; but if it contains one, an effervescence takes place.

If this solution in the acid is colourless, we may conclude that it contains no metallic oxide, or only a very small portion; if its colour is purplish red, it contains manganese; if brownish-red indicates the presence of iron; and golden yellow the presence of chromium.

This solution is to be poured into a capsule of porcelain, covered with paper, and evaporated to dryness in a sand-bath. When the evaporation is finished towards its completion, the liquor assumes the form of jelly. It must then be stirred constantly with a glass or porcelain rod, in order to facilitate the separation of the acid and water, and to prevent one matter from being too much, and another not sufficiently, dried. Without this precaution, the silica and alumina would not be completely separated from each other.

When the matter is reduced almost to a dry powder, a large quantity of pure water is to be poured on it; and, after exposure to a slight heat, the whole is to be poured on a sieve. The powder which remains upon the sieve is to be washed repeatedly, till the water with which it has been washed ceases to precipitate silver from its solutions. This powder is the whole of the silica which the stone that we are analysing contained. It must first be dried between folds of blotting paper, then heated red-hot in a platinum or silver crucible, and weighed while it is yet warm. It ought to be a fine powder, of a uniform colour, not adhering to the fingers, and easily soluble. If it is coloured, it is contaminated with some metallic oxide; and shews that the evaporation to dryness has been performed at too high a temperatute. To separate this oxide, the silica must be precipitated repeatedly, till it is washed and dried as before. The acid solution must be added to the water which passed through the filter, and which we shall denominate A.

The watery solution A is to be evaporated till its quantity does not exceed 30 cubic inches, or nearly an English pint. A solution of carbontat of potassa is then to be poured into it, till no more mater precipitates. It ought to be boiled a few moments to enable all the precipitate to fall to the bottom. When the whole of the precipitate has collected at the bottom, the supernatant liquid is to be decanted off; and water being substituted in its place, the precipitate and water are to be thrown upon a filter. When the water has run off, the filter with the precipitate upon it is to be placed between the plates of blotting paper. When the precipitate has acquired some consistence, it is to be carefully collected by an ivory knife, mixed with a solution of pure potassa, and baked in a porcelain capsule. If any alumina...
or glucina is present, they will be dissolved in the potass; while the other substances remain untouched in the form of a powder, which we shall call B.

Into the solution of potass as much acid must be poured as will not only dissolve the potass, but also completely redissolve any precipitate which may have at first appeared. Carbonate of ammonia is now to be added in such quantity that the liquid shall taste of it. By this addition the whole of the alumina in the precipitate will be rendered precipitate in white flakes, and the glucina will remain dissolved, provided the quantity of carbonate of ammonia used is not too small. The liquid is now to be filtered; and the aluminium which will remain on the filter is to be washed, dried, heated red-hot, and then weighed. To see if it is really alumina, dissolve it in sulphuric acid, and add a sufficient quantity of sulphat of acetat of potass; if it is alumina, the whole of it will be converted into crystals of alum.

Let the liquid which has passed through the filter be boiled for some time; and the glucina, if it contains any, will be precipitated in a light powder, which may be dried and weighed. When pure, it is a fine, soft, very light powder, which does not concret when heated, as alumina does.

The residuum B may contain lime, magnesia, and one or more metallic oxides. Let it be dissolved in weak sulphuric acid, and the solution evaporated to dryness. Pour a small quantity of water on it. The water will dissolve the sulphat of magnesia and the metallic sulphats; but the sulphat of lime will remain undissolved, or if any portion dissolves, it may be thrown down by the addition of a little weak alcohol. Let it be heated red-hot in a crucible, and weighed. The difference of the weights will give the weight of the lime.

Let the solution containing the remaining sulphats be diluted with a large quantity of water, and let a small excess of acid be added; and after being heated, let the liquid be decanted off. Let the precipitate, which consists of the oxides of iron and nickel, be washed with pure water; and let this water be added to the solution of the nitric acid and potass. That solution contains the chromium converted into an acid. Add to this solution an excess of muriatic acid, and evaporate till the liquid assumes a green colour; then add a pure alkali. The chromium precipitates in the state of an oxide, and may be dried and weighed.

Let the precipitate, consisting of the oxides of iron and nickel, be dissolved in muriatic acid; add an excess of ammonia; the oxide of iron precipitates. Let it be washed, dried, and weighed.

Evaporate the solution, and the oxide of nickel will also precipitate, or the whole may be precipitated by adding hydroxyluret of ammonia; and its weight may be ascertained in the same manner as before on the other ingredients.

The weights of all the ingredients obtained are now to be added together, and their sum total compared with the weight of the matter submitted to analysis. If the two are equal, or if they differ only by .03 or .04 parts, we may conclude that the analysis has been properly performed; but if the loss of weight is considerable, something or other has been lost. The analysis must therefore be repeated with all possible care. If there is still the same loss of weight, we may conclude that the stone contains some substance, which has either evaporated by the heat, or is soluble in water.

A fresh portion of the stone must therefore be broken into small pieces, and exposed in a porcelain crucible to a strong heat. If it contains water, or any other volatile substance, it will come over into the receiver, and the pure stone will remain unattainable.

If nothing comes over into the receiver, or if what comes over is not equal to the weight weighing, we may conclude that the stone contains some ingredient which is soluble in water.

To discover whether it contains potass, let the stone, reduced to an impalpable powder, be boiled five or six times in succession with very strong sulphuric acid, applying a pretty strong heat towards the end of the operation, in order to expel the excess of acid; but taking care that it is not hot enough to decompose the salts which have been formed.

Water is now to be poured on; and the residuum, which does not dissolve, is to be washed with water till it becomes tasteless. The watery solution is to be filtered, and evaporated to dryness, in order to drive off any excess of acid which may be present. The salts are to be again dissolved in water; and the solution, after being boiled for a few moments, is to be filtered and evaporated to a consisting proportion of the acid.

If the residuum cannot be dissolved, add a sufficient quantity of alumina; or if it is not sufficient, let it be redissolved, and then evaporated to dryness, and the residuum again dissolved in water, and evaporated.

Sulphat of potass will crystallize first; and by a second evaporation of the stone, contains potass and alumina, crystals of alum will be deposited.

STONES.

Soda, the presence of this alkali may be discovered by decomposing the solution in sulphuric acid, already described, by excess of ammonia. The liquid that is to be evaporated to dryness, and the residuum is to be calcined in a crucible. By this method, the sulphat of potass will be volatilized, and the sodas will remain. It may be redissolved in water, crystallized, and examined.

If sulphuric acid does not attack the stone, as it is often the case, it must be decomposed by fusion with soda, in the same manner as formerly directed with potass. The matter, after fusion, is to be diluted with water, and then saturated with sulphuric acid. The solution is to be evaporated to dryness, the residuum again dissolved in water, and evaporated. Sulphat of soda will crystallize first; and by a second evaporation of the stone, contains potass and alumina, crystals of alum will be deposited.

STONES, earthy. Crooked divided this order into nine genera, corresponding to nine earthly species, one of which had disposed the stones arranged under each genus.

The names of his genera were, calcarce, silicea, graminea, argillacea, mucedus, flores, asbestina, zeolithica, magnesia. All his earths were afterwards found to be compounds, except the first, second, fourth, and fifth. Bergman, therefore, in his Scagrophilia, first published in 1782, reduced the number of genera to five; which was the number arbitrary, which he wrote. Since that period five new earths have been discovered. Accordingly, in the latest systems of mineralogy, the genera belonging to this order are proportionately increased. Each genus is named from an earth, as follows:

2. Siliceous genus.
3. Calcareaous genus.
5. Baryte genus.
6. Argillaceaous genus.
7. Stonian genus.

Mr. Kirwan, in his valuable system of mineralogy, has adopted the same genera. Under each genus, the stones are composed chiefly of the earth which gives a name to the genus, or which at least are supposed to possess the characters which distinguish that earth.

A little consideration will be sufficient to discover that there is no natural foundation for these genera. Most stones are composed of two, three, or even four ingredients; and in many cases the proportion of two or more of these is nearly equal. Now, under what genus soever such minerals are arranged, the earth which gives it a name must form the smallest part of their composition. Accordingly, it has not been so much the chemical composition, as the external character, which has guided the mineralogist in the distribution of his species. The genera cannot be properly to have any character at all, nor the species to be connected by anything else than an arbitrary title. This defect, which must be apparent in the most valuable systems of mineralogy, seems to have arisen chiefly from an attempt to combine together an artificial and natural system.

The order of the substances enter into the minerals belonging to this order, in such quantity as to deserve attention, are the following:
Slate, sand. Under this arrangement are comprehended all the minerals which have an earthy basis combined with an acid. The minerals belonging to it are of course salt and as such have been described under their respective names. But as they occur naturally in states which cannot always be imitated by art, it will be necessary to take a view of them as they are found in the earth. They naturally divide themselves into five general as only five earthy bases have hitherto been discovered native in combination with an acid. These genera, and the species belonging to them, are the following:

I. Calcareous Salts.
1. Carbonate of lime,
2. Sulphate of lime,
3. Phosphate of lime,
4. Fluorescent of lime,
5. Arsenate of lime.

II. Barytic Salts.
1. Carbonate of barytes,
2. Sulphate of barytes.

III. Iron Salt.
1. Carbonate of iron,
2. Sulphate of iron.

IV. Magnesium Salts.
1. Sulphate of magnesia,
2. Carbonate of magnesia,

V. Aluminous Salts.
1. Alum,
2. Mellat of aluminia,

The minerals belonging to this order are distinguished without much difficulty from the last. All of them are soluble in water; but soluble in nitric acid, or in hot sulphuric acid. Most of them melt before the blowpipe. Their specific gravity varies; but it is often above 3.5 when the mineral is too soft to make a glass. None of them have the metallic lustre.

Stonehenge, in antiquity, a famed pile or monument of huge stones on Salisbury Plain, six miles distant from that city. It consists of the remains of four ranks of rough stones, ranged one within another, some of them, especially in the outermost, and third rank, twenty feet high, and seven broad: sustaining others laid across their heads and fastened by mortises, so that the whole must have answeringly lain together. Antiquaries are now pretty well agreed that it was a British temple; and Dr. Langwith thinks it might easily be made probable at least, that it was dedicated to the sun and moons.

Stone Ware. Under the denomination stone ware are comprehended all the different artificial combinations of earthy bodies which are applied to useful purposes. These vary in their names according to their external appearance, the manner in which they are manufactured, and the purposes to which they are applied. Thus we have porcelain, stone ware, pots, crucibles, &c., and these substances, however, are formed on the same principles, nearly of the same materials, and owe their good qualities to the same causes.

These combinations have been known from the remotest ages of antiquity. They were well known to the Jews, as we learn from the Old Testament, long before the Babylonish captivity. Porcelain, or the finest kind of stone ware, was first made in China and Japan; but the discovery of the art of making it in Europe is of much later date. Specimens of it were brought first from China and Japan to modern Europe. These were admired for their beauty, were eagerly sought after, and soon became the ornaments of the tables of the rich. Various attempts were made to imitate them in different countries of Europe, but the greater number were without success. Accident led to the discovery in Germany about the beginning of the 18th century. A chemist in Saxony, during a set of experiments in order to ascertain the best mixtures for making earthenware, stumbled upon a compound which yielded a porcelain similar to the eastern. In the course of this discovery, Saxony soon produced porcelain scarcely inferior to that of Japan in beauty, and superior to it in solidity and strength: but its composition was kept secret; nor were there any accurate ideas respecting the component parts of porcelain among men of science, till Reaumur published his dissertations on the subject in 1727 and 1729. He examined the porcelain of Japan, and the different imitations of it which had been produced in France and other parts of Europe. The texture of the first was compact and solid, but that of the imitations was porous. When both were exposed to strong heat, the first remained unaltered, but the others melted into glass. From these experiments he drew the following ingenious conclusions:

Porcelain owes its semi-transparency to a kind of semi-vitrification which it has undergone. Now it is produced in two ways:
1. Its component parts may be so easily vitrified when sufficiently heated; but the degree of heat given may be just sufficient to occasion the commencement of vitrification. This porcelain when thus heated with great ease melted. Such, therefore, was the composition of the European imitations of porcelain.
2. It may be composed of two ingredients; one of which easily vitrifies, but the other is not altered by heat. When a porcelain composed of such materials is baked in a sufficient heat, the fusible part melts, envelops the inelastic, and forms a semi-transparent substance, which is further altered by the same degree of heat. Such therefore must be the porcelain of Japan. Father Entrecolles, a missionary to China, had sent an account of the Chinese mode of making porcelain, which coincided exactly with this ingenious thought of Reaumur. The ingredients, according to him, are a hard stone called petusum, which they grind to powder, and a white earth called kaozin is intimately mixed with it. Reaumur found the petusum fusible, and the kaozin inexpressibly resistant, but not separately to a violent heat. See Porcelain.

Stone ware is not formed by mixing together the pure earths, which would be a great deal too expensive; but natural combinations or mixtures of earths are employed. These combinations have the following properties: 1. They must be capable, when reduced to powder, of forming with water a paste sufficiently ductile to be made into any form which is required. 2. This paste, after having been exposed to a sufficient heat, or after being baked as it is termed, must acquire such a permanent degree of hardness as to be able to resist the action of the weather and of water. 3. The vessels formed of it must in that state be capable of enduring changes of temperature. 4. They must be strong and tenacious, and not require a strong heat without being melted. 5. They must not be permeable to liquids, nor liable to be acted on by chemical agents.

Common clay possesses a good many of these qualities. When finely ground, it may be formed into a very ductile paste; heat makes it hard enough to strike fire with steel, and capable of resisting the action of most chemical agents; and it is not liable to be melted by heat. Clay accordingly was the first substance employed, and it is still employed for a variety of purposes.

Bricks, for instance, are always made of this substance. The clay is dug out of the earth, and after it has been exposed to the air, reduced to powder, and mixed with water, the mixture is formed into bricks, and allowed to dry; when it is soaked in water, and then burnt in a large furnace constructed of bricks which are employed for covering houses are formed in the same way. The clay, however, is finer, and it is usually ground in a mill.

Bricks and tiles should be impervious to water; they should be capable of withstanding the action of heat, and not be subject to moulder. It is obvious that these qualities must depend upon the nature of the clay of which they are formed, and on the degree in which they have been burnt. Clay is a mixture of alumina and silica in various proportions. When the proportion of alumina is great, the brick contracts much in its dimensions, and is apt to crack during the burn; but clay containing much silica, being less fusible, is capable of holding together the particles of the clay, and tiles are made contains some oxide of iron, hence the red colour which it acquires when burnt.

But though the addition of lime may be proper in some cases in the manufacture of bricks and tiles, it would be exceedingly improper in other cases. Lime ought to be carefully excluded from the clay destined for making pots, and every other utensil which is to be exposed to a violent heat, as it renders the clay fusible. Now lime enters not unfrequently into the composition of clays. It is evident therefore that all clays are not proper for the manufacture of stone ware. They must be free from lime, barytes, and all other ingredients which renders them fusible. They must also be free from metallic oxides, which not only render them fusible, but also injure the colour of the porcelain. The clays must be refractory, as the following is composed of a mixture of alumina and silica. These are known by the names of potters' clay, tobacco-pipe clay, porcelain-clay, &c., according to
the purposes to which they are applied. It is necessary to mix the clay with fine sand and colour to prevent the vessels from contracting too much during the baking.

Thus stone ware is composed of two materials, pure clay and sand; and the mixture depends upon the purity and fineness of these two materials. What is called English stone ware is composed of tobacco-pipe clay and powdered thite; della ware is composed of clay and fine sand; and the coarsest wares of still more common clay and sand.

The materials are ground very fine in a mill, then mixed together, and formed into a paste. The different vessels are carefully modeled on the potter's wheel, and allowed to dry till they can bear handling. After this they receive their destined form completely; and when they are sufficiently dry, they are covered with the requisite enamel, and then put into the furnace and baked.

The ware of coarse vessels is formed by covering their surface while hot with a little litharge, which has the property of running into an opaque glass at a moderate heat when spread thin upon an earthen vessel. The colour is yellow or red. It is seldom perfect; hence these coarse vessels are frequently porous, and incapable of resisting the action of corrosive substances. Common salt is sometimes employed by the potter. It facilitates the fusion of the surface of stone ware, and occasions a kind of vitrification.

The glazing of fine vessels consists of white enamel. This is made as follows: one hundred parts of lead are melted with from 15 to 40 parts of tin, and the mixture oxidized completely, by exposing it to heat in an open vessel. One hundred parts of this oxide are mixed with 100 parts of a fine white sand composed of three parts silica and one part of talc, and with about 25 parts of common salt. This mixture is melted, then reduced to powder, and formed into a paste, which is spread thin over the porcelain vessel before it is baked. The excellence of a good enamel is, that it easily fuses into a kind of paste at the heat which is necessary for baking porcelain, and spreads equally on the vessel, forming a smooth glassy surface, without losing its opacity, or being completely turned to glass. Its whiteness depends upon the proportion of the tin, its fusibility upon the lead.

Porcelain is always covered with a glass composed of earthy ingredients, without any mixture of metallic oxides. Hence the high temperature necessary to fuse it, and the property which porcelain vessels have of resisting the action of the most corrosive substances, appear to be connected. The only common substance commonly employed is felspar, a mineral of a fine white colour and foliated texture, which is found abundantly in the mountains.

It is usual to paint both stone ware and porcelain of various colours. These paintings are excellent, both in elegance of workmanship and in brilliancy of colour. The colours are given by means of metallic oxides, which are mixed up with other ingredients proper to constitute an enamel, and applied in the usual manner with a pencil.

On this subject much light has been thrown by the experiments of Wedgwood; and Briquart has lately published a general account of the processes at Sevres, of which he is the director.

The process differs a little according to the substance on which the colours are to be applied. When the vessels are covered with enamel, less flux is necessary, because the enamel melts at a low heat, and the colours readily incorporate with it; but this renders them more dilute, and makes it often necessary to retouch them. The colours on enamel generally appear brilliant and soft, and are not liable to scale. The flux is either a white or a tint of black, mixed with felspar, nearly the same as those applied on enamel, but more flux is necessary. They are not liable to dilution, as the felspar glass does not melt at the heat requisite for fusing the colours properly. Their cohesion is liable to scale of when repeatedly heated.

Colours are sometimes applied over the whole surface of the porcelain; the flux in that case is porcelain. But such colours are not numerous, because few oxides can stand the heat necessary for fusing felspar without being altered or volatilized.

1. Purple is given by means of the purple oxide of gold precipitated by the smallest possible quantity of muriatic acid. This oxide is mixed with a proper quantity of powdered glass, borax, and oxide of antimony, and applied with a pencil. It cannot bear a strong heat without losing its colour.

2. Red is given by oxide of iron. A mixture of two parts of sulphate of iron and one part of alum is calcined slowly, till it acquires a deep red colour when cold. This powder is mixed with the usual flux, and applied with a pencil.

3. Yellow is given by the oxide of silver; or, by oxides of lead, antimony, and sand; green, by the oxide of copper; blue, by the oxide of cobalt; and violet, by the oxide of manganese.

STO, in music, a word applied by violin and violoncello performers to that pressure of the strings by which they are brought into contact with the finger-board, and by which the pitch of the note is determined. Hence a string, when stopped, is said to be stopt.

Strokes of an organ. A collection of pipes similar in tone and quality, which run through the whole, or a great part, of the compass of the instrument. In a great organ the stops are numerous and multifarious, commonly consisting of several strokes.

Open-dispasion stop. A metallic stop which commands the whole scale of the organ, and which is called open in contradistinction to the stop dispassion, the pipes of which are closed at the top.

Stop-dispasion stop. A stop, the pipes of which are generally made of wood, and its base up to middle C always of wood. They are only half as long as those of the open dispasion, and are stopped at the upper end with wooden stoppers or plugs, which render the tone more mellow and gentler than that of the open dispasion.

Principal stop. A metallic stop originally distinguished by that name, because holding the pitch, the middle of which is generally between the dispassion and fifteenth, it forms the standard for tuning the other stops.

Twelfth stop. A metallic stop so denominated from its being tuned twelve notes above the dispassion. This stop, on account of its pitch, or middle, can never properly be used alone. The open dispasion, stop dispassion, principal, and fifteenth, are the best qualified to accommodate to the ear.

Fifteenth stop. A stop which derives its name from its pitch, or scale, being fifteen notes higher than that of the dispassion. This stop and the twelfth, mellowed and embodied by the two dispassions and principal, form a proper compound for accompanying chord parts in common choirs and parochial churches.

Sesquialtera stop. A mixed stop running through the scale of the instrument, and consisting of three, four, and sometimes five ranks of pipes, tuned in thirds, fifths, and sometimes an small organ pipe, which is stopped at the middle station between the dispassion and fifteenth, it forms the standard for tuning the other stops. The pipe is divided at middle C, when the lower part is called the sesquialtera, and the upper part the cornet. The whole of the stop lies above the fifteenth; the first rank being a seventeen, the second to a twenty-first, and the third rank a twenty-second, above the dispassion.

Mixture or furniture stop. A stop comprising two or more ranks of pipes, similar than those of the sesquialtera, and only calculated to be used together with that and other stops. The mixture is nearly the same as the sesquialtera, and greatly enriches the instrument.

Trumpet stop. A mixed metallic stop, so-called because its tone is imitative of the trumpet. In large organs it generally extends through the whole compass. The mouths of its pipes are not formed like those of the pipes of other stops, but resemble that of the real trumpet. At the bottom of each of the pipes of this stop, in a cavity called the trumpet, is fixed a brass reed, stop at the lower end, and open in front; it is furnished with a tongue, or brass ring, which covers the opening, which, when the wind is impelled into the pipe, is thereby put into a vibratory motion, which produces the imitative tone peculiar to this stop. The trumpet stop is the most powerful in the instrument, and im-

...
proves the tone, as much as it increases the peal of the choruses. Unisonous with the disquisitions, it strengthens the foundation, subdues the disorders of the thirds and fifths of the sequiquia, and imparts to the compound a richness and grandeur of effect adequate to the subordinate subjects.

Climax or octave trumpet stop. A reed stop resembling the tone of the trumpet, as may be inferred from its name; but the scale of which is an octave higher than the trumpet stop. This stop forms a brilliant supplement to the chorus, and is judiciously employed on occasions which require every power of the instrument; but should not be commonly opened; or, indeed, ever without the other stops.

Thrice stop. A stop which is tuned a major third higher than the quintet, and only employed in the full organ.

Larghetto, or slower tremolo. A stop, the scale of which is an octave above the tremolo. Only used in the full organ.

Cercat stop. A stop consisting of five pipes to each note, tuned somewhat in the manner of sesquialtera, having beside the union of the diapason, its third, fifth, eighth, and seventeenth. The cornet being only a treble stop, it is employed in parvis-churches, &c. in conjunction with the diapason in interludes, and of giving out of the psalms.

Dalcroze stop. A stop in the choir organ of a peculiar sweetness of tone, which it chiefly derives from the bodies of its pipes being longer and smaller than those of the other stops. It is in union with the diapasons, and equals them in compass upward, but only descends to G gamut.

Flute stop. A stop imitative of the common flute, or flagello. It is in union with the principal, but of a much softer tone than that stop.

Basso-suite stop. A reed stop imitative of the instrument from which it derives its name. This stop, so far as it extends upward in the scale, is in union with the diapasons, in company with which it only ought to be used.

Fox hunting stop. A reed stop, the tone of which, as its name implies, resembles the human voice in the quality of this stop. It is in union with the diapason, and with which it is in union.

Hunting stop. A reed stop voiced in imitation of the hunting. It is in union with the diapasons, with which it only should be used.

Cremora stop. A reed stop in union with the diapasons. The name of this stop has induced most organ-builders erroneously to suppose that it was originally meant as an imitation of the Cremora violin; but the writers best informed upon the subject inform us, that it was designed to imitate an ancient instrument called a krummhorn, which word has been corrupted into cremona.

STOOGSTAGE, for the subsistence of the sick. In the regulations for the better management of the sick in regimental hospitals, it is said, legally laid down, under the head subsistence, page 16, that sufficient funds should be established for the support of the sick without any additional charge to government; and at the same time, that the sick soldier should be provided with every reasonable comfort and indulgence that can be afforded. The sum of four shillings per week from the pay of each soldier will, under proper regulations, and with strict economy, be sufficient for this purpose; which sum is to be retained by the paymaster of the regiment.

The sick are to be furnished with bread made of the finest wheat-dour, and fresh meat, perfectly good and wholesome.

That the greatest economy may be used in laying out the money for the sick, every article ought to be paid for, by the surgeon, who is required to keep a book, in which he is to enter the amount of the weekly consumption of each man according to the diet table; and this book, with the diet table, is to be laid before the commanding officer and paymaster every week, to be examined and signed by each.

STOPPAGE, in a military sense, deductions from a soldier's pay, the better to provide him with necessaries, &c. A soldier should never be put out of the service, unless purchased by the surgeon, from his pay, than what will afterwards leave him a sufficiency for meaning. Since the abolition of arrears a regulation has taken place, by which soldiers are directed to be stopped one shilling per week, or as much as the expense per week in the infantry, and to be accounted with on the 24th of every month.

STORAX. See STORAX, and RESINS.

STORES. If any person who has the charge or custody of any of the king's armament, ordnance, ammunition, shot, powder, or habiliments of war, or of any victuall for victualling the navy, shall, to hinder his majesty's service, embezze, purloin, or convey away the same to the value of 20s. or shall real or embezze any of his majesty's sails, cordage, or any other materials of war, to the value of 20s. he shall be adjudged guilty of felony without benefit of clergy. 22 Car. II. c. 5.

The treasurer, comptroller, surveyor, clerk of the acts, or any commissioner of the navy, may act as justices in causing the offender to be apprehended, committed, and prosecuted for the same. 9 G. III. c. 30.

If any person shall wilfully and maliciously set on fire, or shall wilfully, presume, or in any manner, hinder his majesty's military, naval, or victualling stores, or other ammunition of war, or any place where any such stores or ammunition shall be kept, he and his attornets shall be guilty of felony without benefit of clergy. 12 Geo. III. c. 24.

STORK. See ABEA.

STOKE, in gardening. See HOT-HOUSE.

STRANGER, among seamen, is a man of a ship that is driven ashore by a tempest, or whom a ship, missing the proper course, runs on shore; it also signifies into what places. Where any vessel is stranded, the justices of the peace are empowered to command the constables near the sea-coast to call assistance, in order to preserve the same if possible.

STRANGURY. See MEDICINE.

STRAP, in a ship, is a rope spliced about any block, or made with an eye, to fasten an object to any other occasion.

STRATA, in the history of the earth, the several beds or layers of different matters, which eave the body of the earth is composed. See Earth, structure of.

SUTURE, of the earth. Scarcely any of the natural phenomena have been slightly treated of by the philosophers of the present and past ages, as the strata of the earth. Few, if any, among the writers on this curious and interesting subject, have distinguished between the undisturbed or regular strata, forming the solid matter of the earth, and the strata violently moved, and worn substances, which are found upon its surface; while these, again, in their observations, have been in too many instances confused with the alluvial deposits. Nevertheless, we have been formed in modern times, or since they have been confined nearly to their present limits. The effects of vegetation, in accumulating peaty matters, and, in conjunction with frost, alternate wetting and drying, the atmosphere, and cultivation, in gradually changing the surface of almost any of the stratified matters, to a soil or mould fit for the growth of some kind of vegetables, have in a great degree been over-cast, and accordingly we find a great number of writers, confidently mentioning different series of substances, which they assert, on observations entirely local, to be the order of the strata on proceeding downward, or upward, in modern times.

Notwithstanding that Mr. Hanksbee many years ago, at the instance of the Royal Society of London, carefully examined a succession of thirty strata, in the shaft of a col-pit, and found that strata specifically heavier, were frequently found lodged above lighter strata; yet, a large portion of the writers since to the present time, have contended that the strata are found deposited in the order, or nearly, of their specific gravities.

John Stracey, esq. a writer in the Philosophical Transactions (No. 391), started an opinion, that the strata were at first formed while in a soft state, as so many wedges, each pointing to and terminating in the centre of the earth; and that by the diurnal revolution of the earth from west to east, these became bent into spirals (as represented in fig. 223, Plate Miscell.), in which case, says he, "there needs no specific gravitation to cause the heavier stratum to be overthrown by the lighter one in its turn, in some place of the globe or other, it will be uppermost," this last remark, made in the year 1725, we do not remember to have been noticed by any subsequent writer or observer, although, from a series of minute observations made within the last fifteen years by a gentleman formerly resident at Mitford near Bath, and now in London, Mr. William Smith, there is great reason to think that this is really the case with all the strata composing the surface of the British islands, and perhaps of the whole earth, in what manner soever the strata in the inner parts of the earth may be disposed.

We do not understand that Mr. Smith was at all acquainted with the above remark of Mr. Stracey; but that in the exercise of his profession of a land-surveyor, superintendent of some coal-mines, and engineer for the cutting of the Somerset coal-canal, he saw ample reason to conclude that the several strata in the section he had described, were laid down successively, and not likewise contemplicably.
STRAWBERRY. See Fragaria.

STRAWBERRY-tree. See Arborus.

STRELITCHIA, a genus of the class and order pentandria monogynia. The spathes are universal and partial; the calyx; corolla are three-petalled; perianth three-leaved; capsule three-celled; fruits many-seeded. There are two species of this magnificent plant, natives of the Cape.

STRENGTH. See Timber, strength of.

STREPTIUM, a genus of the didynamia angiosperma class and order. The calyx is five-toothed; stigma two-lipped; drupe two lobed. There is one species.

STRIE, a measure of capacity, containing four hundred cubic feet. See Measure.

STRIE, among seamen, is a word variously used. When a ship, in a fight, or on meeting with a ship of war, lets down or lowers her topsails, at least half the deck high, they say she strikes. If the vessel, meaning the ship, or submit, pays respect to the ship of war. Also, when a ship touches ground, in shoal-water, they say she strikes. And when a topmast is to be taken down, the word of command is, strike the topmast, &c.

STRIX, the owl, in ornithology, a genus belonging to the order accipitres. The bill is hooked, but has no crest or wax; the nostrils are covered with setaceous feathers; the head and whole body finely variegated with lines, spots, and specks of black, brown, cinnereous, and ferruginous; wings long; tail short, marked with dusky bars; legs thick, covered to the very end of the toes, with a claw; the plumage of a testaceous colour; claws great, much hooked and dusky. It has been shot in Scotland and in Yorkshire. It inhabits inaccessible rocks and desert places, and preys on hares and

3. The estrich, or ostrich, weighs 19 ounces. This is a landier species than the former; and the young will feed on any dead thing, whereas those of the white owl must have a constant supply of fresh meat. It is the strix of the Hindus. The screech-owl, to which the foible of superstition has given the power of preying death by its cries.

4. The ulula, or brown owl, agrees with the former in its marks, differing only in the subjection of the black, but differs in the size of the head and neck. It is found in the United States, and in the black, or brown owl, with the small black head and neck. It is found in the United States, and in the

5. There the say, two species inhabit one, or two eggs, of an elliptical form, and of a whitish colour.

6. There the say, two species inhabit one, or two eggs, of an elliptical form, and of a whitish colour. They destroy numbers of little leavers, as they say, two species inhabit one, or two eggs, of an elliptical form, and of a whitish colour.

7. There the spectacles in Cayenne, which is accurately described by Dr. Latham, is 21 inches in length; the upper part of the beak is of a reddish colour; the lower parts of a russet white; the head and neck are white, and not so full of feathers as those of the beak. They destroy numbers of little leavers, as they say, two species inhabit one, or two eggs, of an elliptical form, and of a whitish colour.

8. There the spectacles in Cayenne, which is accurately described by Dr. Latham, is 21 inches in length; the upper part of the beak is of a reddish colour; the lower parts of a russet white; the head and neck are white, and not so full of feathers as those of the beak. They destroy numbers of little leavers, as they say, two species inhabit one, or two eggs, of an elliptical form, and of a whitish colour. The Malays use these eggs to decoy small birds to the lined twigs; the method of which is exhibited in Olina's Uccellaria.

9. There the spectacles in Cayenne, which is accurately described by Dr. Latham, is 21 inches in length; the upper part of the beak is of a reddish colour; the lower parts of a russet white; the head and neck are white, and not so full of feathers as those of the beak. They destroy numbers of little leavers, as they say, two species inhabit one, or two eggs, of an elliptical form, and of a whitish colour. The Malays use these eggs to decoy small birds to the lined twigs; the method of which is exhibited in Olina's Uccellaria.
SUBSTANCES. It is sometimes transparent and colourless, but generally has a tinge of yellow or green. Its specific gravity varies from 3.4 to 3.726. Its texture is generally fibrous; but, in a few cases, it is almost like glass, and crystallized in slender prismatic columns of various lengths.

Strontian is found abundantly in different places of the world, and always combined with carbonic acid or sulphuric acid.

1. The carbonic acid may be expelled from the carbonat, and the strontian obtained pure by mixing the mineral with charred wood, and boiling it to a heat of 140° Wedgewood; or by dissolving the mineral in nitric acid, evaporating the solution till it crystallizes, and exposing the crystals in a crucible to a red heat till the nitric acid is driven off.

2. Strontian thus obtained, is in porous masses, of a greyish white colour; its taste is acid and alkaline; and it converts vegetable blues to green. Its specific gravity, according to Hasselratz, is 1.647. It does not act strongly on animal bodies as barytes, nor is it poisonous.

3. It does not melt when heated like barytes: but before the blowpipe it is penetrated with light, and surrounded with a flame so white and brilliant that the eye can scarcely be held.

4. When water is sprinkled on strontian it is slackened, becomes hot, and falls to powder exactly like barytes; but it is not so soluble in water as that earth. One hundred and sixty-two parts of water, at the temperature of 60°, dissolve nearly one part of strontian.

The solution, known by the name of strontian water, is clear and transparent, and converts vegetable blues to a green. Hot water dissolves it in much larger quantities; and as it cools, the strontian is deposited in colourless transparent crystals. These are in the form of thin quadrangular plates, generally parallelograms, the largest of which seldom exceeds one-fourth of an inch in length. Sometimes their edges are plain, but they often consist of two facets, meeting together, and forming an angle like the roof of a house. These crystals generally adhere to each other in such a manner as to form a thin plate of an inch or more in breadth. Sometimes they assume a cubic form. They contain about 68 parts in 100 of water. They are soluble in 51.4 parts of water, at the temperature of 60°. Boiling water dissolves nearly half its weight of them.

When exposed to the air, they lose their water, attract carbonic acid, and fall into powder. Their specific gravity is 1.46.

5. Strontian is not acted on by light; neither does it combine with oxygen.

6. Sulphur and phosphorus are the only simple combustibles with which it unites.

The sulphuret of strontian may be made by fusing the two ingredients in a crucible. It is soluble in water, and is called strontian sulphur, which is evolved. When the solution is evaporated, hydrosulphuret of strontian is obtained in crystals, and hydrogenated sulphuret remains in solution. These compounds resemble almost exactly the sulphide, sulphuret, and hydrogenated sulphuret of barytes; and, do not therefore require a particular description. The same remark applies to the phosphuret of strontian, which may be prepared by the same process as the phosphuret of barytes.

7. Strontian has no action upon metals; but it combines with several of their oxides, and forms compounds which have not hitherto been examined.

8. It does not combine with alkalies nor with barytes. No precipitation takes place when barytes and strontian water are mixed together.

9. Strontian has the property of tingling flame of a beautiful red, or rather purple colour; a property discovered by Dr. Ash in 1757. The experiment may be made by fusing a little of the salt composed of nitric acid and strontian into the wick of a lighted candle; or by setting fire to alcohol, holding muriat of strontian in solution. In both cases the flame is of a lively purple. In this case the sulphuret of strontian was tried in the same way is found to comminute a blueish yellow tinge to flame.

10. The affinities of strontian, as ascertained by Dr. Hope and Mr. Vauquelin, are as follows:

- Sulphuric acid, Muratic acid, Oxalic acid, Tartaric acid, Acetic acid, Fluoric acid, Boracic acid, Nitric acid, Carbonic acid.

Barytes and strontian resemble each other in their properties as closely as potash and soda: hence, like these two alkalies, they were for some time confounded. It is in their combination with acids that the most striking differences between these two earths are to be observed.

STRUMPFIA a genus of plants belonging to the class of Syngenesia, and to the order of Monogonnia. The calyx is quinquedentate and superior; the corolla is pentapetalous; and the seeds monospermous. There is only one species, the maritima, a shrub of Curacao.

ST RUTTHIO, in natural history, a genus of birds belonging to the order of Grallae, and to the family of Lignores. It includes, The ostrich, has a bill somewhat conical; the wings are so short as to be unfit for flying; the thighs and sides of the body are naked; the feet are formed for running, having two toes, one only of which is furnished with a nail. The head and bill somewhat resemble those of a duck; and the neck may be likened to that of a swan, but that it is much longer; the legs and thighs resemble those of a hen, though the whole of its body bears a strong resemblance to that of a camel. But though usually seven feet high from the top of the head to the ground, from the back it is only four; so that the head and neck are above three feet long. From the top of the head to the rump, when the neck is stretched out in a right line, it is six feet long, and the tail is about a foot more. One of the wings without the feathers, is a foot and a half; and being stretched out, with the feathers, is three feet in length. Its plumage is much alike in all; that is generally black and white; though some of them are said to be grey. There are no feathers on the sides, nor yet on the thighs, nor under the wings. The lower part of the neck, about half-way, is covered with still smaller feathers than those on the belly, and back; and those also are of different colours.

At the end of each wing there is a kind of spur almost like the quill of a porcupine. It is an inch long, being hard and of a horn-like substance. There are two of these on each wing; the largest of which is at the extremity of the bone of the wing, and the other a foot lower. The neck seems to be more slender in proportion to that of other birds, from being further furnished with feathers. The skin in this part is of a livid flesh-colour, which some improperly would have to be blue. The bill is short and pointed, and two inches and a half at the beginning. The external form of the eye is like that of a man. The upper eyelid is adorned with eye-lashes which are longer than those on the lid below. The tongue is small, very short, and composed of cartilages, ligaments, and membranes, intermixed with fleshy fibres. In some it is about one inch long, and very thick at the bottom; in others it is but half an inch, being a little forked at the end.

The ostrich is a native only of the torrid regions of Africa, and has long been celebrated by those who have had occasion to mention the animals of that region. Its flesh is proscribed in scripture as unfit to be eaten; and most of the ancient writers describe it as well known in their times. Like the race of the elephant, it is transmitted down without mixture; and has never been known to breed out of that country which first produced it. It seems formed to live among the sandy deserts, and is altogether unlike the poult. In some measure it owes its birth to its general infirmity, so it seldom migrates into tracts more mild or more fertile. The Arabs assert that the ostrich never drinks; and the place of its habitation seems to confirm this assertion. In these formidable regions owls and vultures are seen in large flocks, which to the distant spectator appear like a regiment of cavalry, and have often alarmed a whole caravan. There is no other feathered bird of such bulk: they are so heavy that they cannot fly, but run at the rate of thirty miles an hour. They devour leather, grass, hair, iron, stones, or any thing that is given. Those substances which the coats of the stomach cannot soften, pass whole; so that glass, stones, or iron, are excluded in the form in which they were devoured.

In their native deserts, however, it is probable they live chiefly upon vegetables, where they lead an inoffensive and social life; the male, as Thernovius assures us, assorting with the female with fidelity. They are said to be very much inclined to venery, and the make of the parts in both sexes seems to confirm the report. It is probable also they copulate like other birds, by compression of the ventricle. Their eggs are inbo in diameter, and weighing above fifteen pounds. These eggs have a hard shell, somewhat resembling those of the crocodile, except that those of the latter are less and rounder.

The season for laying depends on the climate where the animal is bred. In the north-
struthios. all known animals, the ostrich is by far
the swiftest in running; upon observing itself,
therefore, pursues, at a distance, he begins to
run at first but gently; either insensible of
his danger, or sure of escaping. Unfortunately
for the silly creature; instead of going off in a
straight line, he takes his course in circles:
while the hunters still make a small course
within, relieve each other, meet him at unex-
pected turns, and keep him still employed,
still followed, for two or three days together.
At last, with fatigue, and finding all power of escape impossible, he
endeavours to hide himself from those enemies
he cannot avoid, and covers his head in the
sand or the first thicket he meets. Some-
times, however, he attempts to face his pursuers;
and though in general the most gentle
animal in nature, when driven to desperation
he defends himself with his beak, his wings,
and his feet. Such is the force of his motion,
that a man would be utterly unable to with-
stand him if he was not wounded:
the Struthophagi have another method
of taking this bird; they cover themselves
with an ostrich's skin, and passing up an arm
through the neck, thus counterfeit all the mo-
tions of this animal. By this artifice they
make the bird believe the ostrich, and
himself an easy prey. He is sometimes also taken by dogs
and nets; but the most usual way is that men-
tioned above.

When the Arabians have thus taken an or-
strich they cut its throat; and making a liga-
ment below the opening, they shut the bird
as one would rim a barrel; then taking off the
ligature, there runs out from the wound
in the throat a considerable quantity of blood
mixed with the fat of the animal; and this is
considered as one of their dainties.

They next lay the bird; and of the skin,
which is strong and thick, sometimes make a
kind of vest, which answers the purposes of
a corseus and a buckler.

There are others who, more compassionate
or, perhaps, more curious to kill their captives,
but endavour to tame it, for the purposes of
supplying those feathers which are in so great
request. The inhabitants of Daara and Lybia
breed up whole flocks of them, and they are
taken for the sake of their feathers; it is not
for their feathers alone that they are prized in
this domestic state; they are often ridden
upon and used as horses. Moore assures us,
that at Jorf, he saw a man travelling upon an
orstrich; and Addison asserts, that at the fac-
tory of Podere he had two ostriches, which
were then young, the strongest of which ran
swifter than the best English racer, al-
though he carried two negroes on his back.
As soon as the negroes perceived that it was
thus loaded, it set running with all its force,
and made several circuits round the village;
 till at length people were obliged to stop it by
barring up the way. How far this strength
and swiftness may be useful to mankind, even
in a polished state, is a matter that perhaps
deserves inquiry. See Plate Nat. Hist. fig. 359.

2. the casowary (the casaurina of Lin-
neus; and galeated casowary of Dr. Latham)
was discovered by Europeans on Java in the
Dutch about the year 1597. It is nearly
equal in size to the ostrich, but its legs are
much thicker and stronger in proportion.
This conformation gives it an air of strength
and force, which the gaveness and singularity
of its countenance conspire to render
formidable. It is five feet and a half long from
the point of the bill to the extremity of the
claw. The legs are two feet and a half high
from the ground to the tips of the claws.
The head and neck together are a foot
and a half; and the largest toe, includ-
ing the claw, is five inches long. The claw
alone of the least toe is three inches and a
half in length. The wings are so small that it does
not appear, it being hidden under the fea-
theers of the back. In other birds, a part of
the feathers serve for flight, and are different
from those that serve merely for covering;
but in the casowary all the feathers are of
the same kind, and outwardly of the same colour.

They are generally double, having two long
shafts, which grow out of a short one, which
is fixed in the skin. Those that are double
are always of unequal length; for some are
fourteen inches long, particularly on the rump,
while others are not above three.
The boards that adorn the stem or shaft
are about half-way to the end, very long, and
as thick as a horse-hair, without being divided
into fibres; the board, it is flat, shining, black, and knotted below;
and from each knot there proceeds a board;
likewise the beak at the end of the large
feathers are perfectly black, and tapers
from the root of a grey fawny colour; shorter,
more soft, and throwing out fine fibres like
down; so that nothing appears except the ends,
which are hard and black; because the other
part, composed of down, is quite cover-
ted. There are feathers on the rump and
neck; but they are so short and thinly shorn,
that the bird's skin appears naked, except to-
wards the hinder part of the head, where
they are a little longer. The feathers which
adorn the rump are extremely thick; but do
not differ in other respects from the rest,
except in their being longer. The wings,
when they are deprived of their feathers, are
but three inches long; and the feathers are
like those on other parts of the body; the ends
of the wings are adorned with five
prickles, of different lengths and thickness,
which bend like a bow: these are hollow from
the root to the very points, having only that
part of the blade that is in the middle,
which is known to have. The longest of these
prickles is eleven inches; and it is a quarter of an
inch in diameter at the root, being thicker there
than towards the extremity; the point seems
broken off.

The part, however, which most distinguishes
this animal is the head; which, though small,
like that of an ostrich, does not fail to inspire
some degree of terror. It is bare of feathers,
and covered with a kind of horn, which is
formed of a kind of horny substance, that covers it from the root
of the bill to near half the head backwards.
This helmet is black before and yellow be-
hind. Its substance is very hard, being form-
ined by the elevation of the bone of the skull;
and it consists of several plates one over an-
other, like the horn of an ox. The neck is of
a violet colour, inclining to that of slate; and
its red behind in several places, but chiefly
in the middle. About the middle of the back,
the largest feathers, these are the two process
formed by the skin, which resemble somewhat the gills of a cock, but
that they are blue as well as red. The skin
which covers the fore part of the breast,
which this bird bears and rests, is hard, callous, and without feathers.

The same degree of voracity which we perceive in the ostrich obtains as strongly here. The cassowary swallows every thing that it can find, without regard to the capacity of the gullet. The Dutch assert, that it can devour not only glass, iron, and stones, but even live on burning coals, without testifying the smallest fear of feeling the least injury. It is said, that the Cassowary can cut through the beams of a house in this manner. These birds have been known to swallow whole eggs which it has swallowed whole, and even the very eggs which it has swallowed whole, pass through it unbroken in the same form they went down. In fact, the alimentary canal of the Cassowary, as observed above, is extremely short; and it may happen, that many kinds of food are indigestible in its stomach, as wheat or currants are to a man when swallowed whole.

The cassowary's eggs are of a grey ash-colour, inclining to green. They are not so large as that of the domestic fowl, as the size of the female. They are marked with a number of little tubercles of a deep green, and the shell is not very thick. The largest of these is found to have fifteen inches round one way, and about twelve in the other way.

The southern parts of the most eastern Indies seem to be the natural climate of the cassowary. His domain, if we may so call it, begins where that of the ostrich terminates. The latter has never been found beyond the Ganges; while the cassowary is never seen nearer than the islands of Banda, Sumatra, Java, the Molucca islands, and the corresponding parts of the continent. Yet even here this annual seems not to have multiplied in any considerable degree, as we find only one of the kings of Java making a present of one of these birds to the captain of a Dutch ship, considering it as a very great rarity.

The casuarus Nova Hollandiae, or New Holland cassowary, differs considerably from the common cassowary. It is a much larger bird, standing higher on its legs, and having the neck longer than in the common one. Total length seven feet two inches. The bill is not greatly different from that of the common species; but the lower appendage or helmet on the top of the head in this species is totally wanting: the whole of the head and neck is also covered with feathers, except the throat and fore part of the neck about half-way, which are not so well feathered as the rest; whereas in the common cassowary the head and neck are bare and carenunculated as in the turkey.

The plumage in general consists of a mixture of brown and grey, and the feathers are somewhat curved or bent at the ends in the natural state: the wings are so very short as to be totally useless for flight, and indeed are scarcely to be distinguished from the rest of the plumage, was it not for their standing up a little. The long spines which are seen in the wings of the common sort are in this not observable, nor is there any appearance of a tail. The legs are stout, formed much as in the ga- lopin. With the addition of their being jaggied or sawed the whole of their length at the back part.

This bird is not uncommon in New Hol- land, as several of them have been seen about Botany Bay and other parts. Although it cannot, it runs so swiftly, that a greyhound can scarcely overtake it. The flesh is said to be in taste not unlike beef.

STRUTHIOLA, a genus of plants belonging to the class of tetrandria, and order of monogynia. The corolla is wanting: the calyx is tubous, with eight glandules at its smooth mouth. In order to judge, and monospermous. The species are 2, shrubs of the Cape.

STYRCHINOS, a genus of plants belonging to the class of pentandria, and order of monogynia; and in the natural system ranging under the 37th order, lianum. The calyx is simple; the style is simple, with a quinqued stigma; the apple is without juice, oval, smooth, monospermous, bursting open with a spring, &c. There are two species, foreign plants.

STUCCO, in building, a composition of white marble pulverised, and mixed with plaster of lime; and the whole being sifted and wrought up with water, is to be used like common plaster: this is called by Pliny mar- moratum opus, and albarium opus.

STUM, in the wine trade, denotes the unfermented juice of the grape, after it has been several times raked off, and separated from its grains.

STURGEON, See Accipenser.

STURNUS, the starking, a genus of birds belonging to the order of passerine. The back is subalutated, depressed, and somewhat blunt; the superior mandible is entire, and somewhat open at the edges; the nostrils are margnated above; and the tongue is sharp and emarginated. There are 13 species, according to Dr. Latham. The vulgaris, capen- sis, ludoviciana, militaris, celtis, carunculat, gallinaceus, securis, viridis, olivaceus, mortinartus, lynca, dauricus, Junerti, and mexicanas.

The vulgaris, or common starking, is the only species of the sturnus that is indigenous. The weight of the male of this species is about three ounces; that of the female rather less. The length is eight inches three quarters. The whole plumage is black, very resplendent, with changeable blue, purple, and copper; each feather marked with a pale yellow spot. The lesser covers are edged with yellow, and slightly glossed with green.

The starks breed in holes in trees, evergreen houses, towers, ruins, cliffs, and often in high rocks over the sea, such as that of the Isle of Wight. It lays four or five eggs, of a pale greenish-yellow color; and makes its nest of straw, small fibres of roots, &c. In winter, starks assemble in vast flocks; they collect in myriads in the fens of Lincolnshire, and do great damage to the men by roosting on the reeds, and breaking them down by their weight; for roots and the like trees of the country, and are laid up in harvest with great care. These birds feed on worms and insects; and it is said, they will get into pigeon-houses, for the sake of sucking the eggs. Their flesh is so bitter as to be scarcely eat- able. They are fond of following oxen and other large cattle, as they feed in the mea- hows, attracted, as it is said, by the insects which flatter round them, or by those, perhaps, which swarm in their dung, or in mea- dows in general. From this habit is derived the Government of the Cape, which lived seven or eight years, or even longer, in the domestic state. The wild ones cannot be des- oyed by the cull, because they regard not the scream of the owl. A method has been discovered of destroying entire families, by laying to the walls and the trees where they lodge pots of earthenware of a convenient form, which the birds often prefer to place their nests in. Many are also caught by the gin and draw-net.

The starks, it is said, can be taught to speak either French, German, Latin, Greek, &c, and to pronounce phrases of some length. Their plant throat accommodates itself to every in- lation and evolution, &c. It can readily ar- ticulate the letter R, and imitates a sort of warbling which is much superior to its native song. This bird is spread through an extensive and extensive, &c. range in the antient continent.

STURNUS, See Plate Nat. Hist. fig. 380, inhabits Europe, Asia, and the northern parts of Persia; frequents waters, and feeds on aquatic insects and small fishes. It is very solitary, and breeds in the holes of banks; the very nest is composed of hay and roots, lined with dead leaves, and having an en- trance of green moss.

STYLO, a word of various significations, originally derived from stylos, a kind of rod-kin, wherein the ancients wrote on plates of lead, or on wax, &c. and which is still used to write on ivory leaves, and paper prepared for that purpose, &c.

STYLE. See DIALLING.

STYLE. See BOTANY.

STYLE, in matters of language. See RHETORIC, and POETRY.

STYLISALPHONY, a genus of fishes of the order apodes. The generic character is: eyes pedunculated, standing on a short thick cylinder; snout lengthened, directed up- wards, retractor towards the head by means of a cæcum, with a great diameter without teeth; branchio three pair beneath the throat; fins, pectoral small, dorsal of the length of the back, caudal short, with spiny rays; body very long, compressed. This highly singular gen- era was first described in the year 1788, by a specimen then introduced into the Leverian Museum, and figured in the first volume of the Linnaean Transactions, see Plate Nat. Hist. fig. 381.

CHONRATODON stylophorus. The head of this extraordinary animal bears some distinct resemblance to that of the genus stylophorus, and its structure cannot so easily be described in words as conceived by the figure. The rostrum or narrow part, which is terminated by the mouth, is connected to the back part of the head by a flexible leathery duplication, which permits it to be either extended in such a manner that the mouth points directly forwards, or to fall back, so as to be received into the Nurse of this tree, as the upper part of the head. On the top of the head are placed the eyes, which are of a form very nearly approaching to that of the genus cancer, except that the columns or parts on which eye is placed, and which are much broader and
The resinous drug called Styrax oregia in a fluid state from incisions made in the trunk or branches of the tree. Two sorts of this resin have been commonly distinguished in the shops: 1. Styrax in the tear, is scarcely, if at all, fit for medicinal purposes, as, sometimes composed of whitish and pale reddish brown tears, and sometimes of an uniform reddish yellow or brownish appearance; unctuous and soft like wax, and free from visible impurities. It is supposed to be the sort which the patients received from Pamphylia in reds or cakes, and which was thence named calamina.

2. Common Styrax: in large masses, consider a lighter and less compact than the former, and having a large admixture of woody matter like saw-dust. This appears to be the kind intended by the London college, as they direct their styrrax calamina to be purified, for medicinal use, by boiling it with boiling water, and pressing it out from the trees by means of warm irons; a process which the first does not stand in need of; and indeed there is rarely any other than this impure Styrax to be met with in the shops.

Styrax, with some of the antecedents, was a familiar remedy as a resolvent, and particularly used in catarrhal complaints, coughs, asthma, menstrual obstructions, &c. and from its affinity to the balsams, it was also prescribed in ulcerations of the lungs, and other sorts of pulmonary consumption. And our pharmacopoeias formerly directed the pilae styrrae; but this odorous drug has now no place in any of the official compounds; and now as a medicine with a reputation to promise some efficacy in nervous debilities, yet by modern practitioners it is almost totally disregarded.

The Styrax benzoin, see Plate Nat. Hist. fig. 393, has been characterized by oblong acuminated leaves, which are downy underneath, and nearly of the length of the racemose flower. This tree, which is a native of Sumatra, is deemed in six years of sufficient age for affording the benzoin, or when its trunk acquires about seven or eight inches in diameter, for the bark is then longitudinally, or somewhat obliquely, at the origin of the principal lower branches, from which the drug exudes in a liquid state, and by exposure to the sun and air soon concretes, when it is scraped off the bark with a knife or chisel. The quantity of benzoin which one tree affords never exceeds three pounds, nor are the trees found to sustain the effects of these annual incisions longer than ten or twelve years. The benzoin which issues first from the wounded bark is the purest, being soft, extremely fragrant, and very white; that which is less esteemed is of a brownish colour, very hard, and mixed with various impurities, which it acquires during its long continuance upon the tree.

The benzoin which we find here in the shops is in large brittle masses, composed partly of white, partly of yellowish or light-brown, and often also of darker-coloured pieces; that which is clearest, and contains the most white matter, called by authors benzoe amygdaloideus, is accounted the best. This resin has very little taste, impressing on the palate only a slight sweetness; its smell, especially when reduced or heated, is extremely fragrant and agreeable. It totally dissolves in rectified spirit (the impurities excepted, which are generally in a very small quantity) into a deep yellowish-red liquor, and in that state discovers a peculiar, sweet and aromatic odour, as well as sweetness. It imparts, by digestion, to water also a considerable share of its fragrance, and a slight pungency; the filtered liquid, gently exhaled, leaves not a resinous or nihiloglous extract, but a sweetish fluid, or rather, seemingly of a saline nature, amounting to one-tenth or one-eighth of the weight of the benzoin. Exposed to the heat in proper vessels, it yields a quantity of a white saline concrete, called styrax benzoes, of an acridulous taste and grateful odour, soluble in rectified spirit, and in water by the assistance of heat.

The principal use of this fragrant resin is in perfumes, and as a cosmetic; for which last purpose, a solution of it in spirit of wine is mixed with so much water as is sufficient to render it milky, as twenty times its quantity or more. It promises, however, to be applicable to other uses, and to approach in virtue, as in fragrance, to Styrax, and balance of the latter. It is said to be of great service in disorders of the breast, for resolving obstructions of the pulmonary vessels, and promoting expectoration: in which intentions the flowers are sometimes given from three to four grains to be dissolved in water, precipitated by water from solutions of the benzoin in spirit, has been employed by some as similar and superior to the flowers, but appears to be little other than the pure benzoin in substance; it is not the saline, but the resinous matter of the benzoin, that is most disposed to be precipitated from spirit by water. The flowers, sniffed up the nose, are said to be a powerful emetic.

SUBALTERN, a subordinate officer, or one who discharges his post under the command and subject to the direction of another: such as lieutenants, sub-lieutenants, cornets and ensigns, who serve under the captain; but custom has now appropriated the term to those of much lower rank, &c.

We also say subaltern courts, jurisdictions, &c. such are those of inferior lords, with regard to the lord paramount; hundred-courts with regard to county-courts, &c.

SUBLAVIAN. See Anatomy.

SUBCOSTAL MUSCLES. See Anatomy.

SUBDUPLE RATIO, is when any number or quantity is contained in another twice: thus 3 is said to be subduple of 6, as 6 is double of 3.

SUBDUPlicate RATIO of any two quantities, is the ratio of their square roots.

SUBER. This name has been introd. into chemistry by Fourcroy, to denote the outer bark of the queucus suber, or the common cork, a substance which possesses properties different from all other vegetable bodies.

It is exceedingly light, soft, and elastic: very combustible, burning with a bright white flame, and leaving a light black bulky charcoal; and when distilled it yields a little ammonia. Nitric acid gives it a yellow colour, corrodes, dissolves, and decomposes it, converting it partly into blue and partly into a substance resembling wax.
SUBERATS, salt formed with the sebamic acid, which see.

SUBERIC ACID may be formed by pouring six parts of nitric acid of the specific gravity 1.2 into one part of cork grated down or simply broken down into small pieces, and distilling the mixture with a gentle heat as long as red vapours continue to escape. As the distillation advances, a yellow matter like wax makes its appearance on the surface of the liquid. While the matter contained in the retort is hot, it is to be poured into a glass vessel, placed upon a sand-bath over a gentle fire, and constantly stirred with a glass rod. By this means it becomes gradually thick. As soon as white vapours, exciting a tickling in the throat, begin to disengage themselves, the vessel is removed from the bath, and the mass continually stirred till it is almost cold.

By this means an orange-coloured mass is obtained of the consistence of honey, of a strong and sharp odour; while hot, but having a peculiar aromatic smell when cold. On this mass twice its weight of boiling water is to be poured, and heat applied till it becomes a liquid that part of it which is insoluble in water is to be separated by filtration. The filtered liquor becomes muddy; on cooling it deposits a powdery sediment, and a thin pellicle forms on its surface. The sediment is to be separated by filtration, and the liquor reduced to a dry mass by evaporating in a gentle heat. This mass is suberic acid. It is still a little coloured, owing to some accidental mixture, from which it may be purified either by saturating it with potassa and precipitating it by means of an acid, or by boiling it along with charcoal powder.

Suberic acid thus obtained is not crystallizable, but when precipitated from potassa by an acid it assumes the form of a powder; when obtained by evaporation it forms thin irregular pellicles.

Its taste is acid and slightly bitter; and when dissolved in small quantity of boiling water it acts upon the throat, and excites coughing.

It reddens vegetable blues; and when dropped into a solution of indigo in sulphuric acid, as it is called in this country), it changes the colour of the solution, and renders it green.

Water at the temperature of 60° or, even 70°, dissolves only 1/5 part of its weight of suberic acid; and if the acid is very pure, only 1/24th part; boiling water, on the contrary, dissolves half its weight of it.

When exposed to the air, it attracts moisture, especially if it is impure.

When exposed to the light of day, it becomes at last brown; and this effect is produced much sooner by the direct rays of the sun.

When heated in a muffle, the acid sublimes, and the inside of the glass is surrounded with zones of different colours. If the sublimation is stopped at the proper time, the acid is obtained on the side of the vessel in small points formed of concentric circles. When exposed to the heat of the blowpipe on a spoon of platinum, it first melts, then becomes sublunent, and at last sublimes entirely with a smell resembling that of sebamic acid.

It is not altered by oxygen gas; the other acids do not dissolve it completely. Alcohol develops an aromatic odour, and an ether may be obtained by means of this acid.

It converts the blue colour of nitrate of copper to a green; the sulphate of copper also to a green; gas of iron to a deep yellow; and sulphate of zinc to a golden yellow.

It has no action either on platinum, gold, or nickel; but it oxidizes silver, mercury, copper, lead, tin, iron, bismuth, arsenic, cobalt, zinc, antimony, and palladium, but not molybdenum.

With alkalis, etca, and metallic oxides, it forms compounds known by the name of suberates.

Its affinities are as follows: Barytes, Potas, Soda, Lime, Ammonia, Magnesia, Alumina.

SUBLIMATION, a process by which certain volatile substances are raised by heat, and again condensed by cold in a solid form. Flowers of sulphur are made in this way. Soot is also an instance of sublimation. See CHEMISTRY.

SUBNORMAL, in geometry, is a line which determines the point in the axis of a curve, where a normal, or perpendicular, raised from the point or contact of a tangent to the curve, cuts the axis. Or the subnormal is a line which determines the point where the axis is cut by a line falling perpendicularly on the tangent in the point of the contact.

SUBPENA, a writ by which all persons under the degree of a peer are called to chancery, in such case only where the common law fails, and has made no provisions; so as the party who in equity has wrong, can have no other remedy by the rules and course of common law. But the peers of the realm in such cases are called by the lord chancellor, or lord keeper, and is, giving notice of the suit intended against them, and requiring them to appear. There is also a subpoena ad testificandum for the summoning of witnesses as well in chancery as other courts.

There is also a subpoena in the exchequer, as well in the court of equity there, as in the office of pleas.

SUBROGATION, or Subrogation, in the civil law, the act of substituting a person in the place, and entitling him in the rights, of another; but, in its general sense, subrogation implies a succession of any kind, whether of a person to a person, or of a person to a thing. There are two kinds of subrogation, the one conventional, the other legal.

Conventional subrogation is a contract, whereby a creditor transfers his debt, with all appurtenances thereof, to the proot of a third person. Legal subrogation is that which the law makes, in favour of a person who discharges an antecedent creditor, in which case there is a legal translation of all rights of the antient creditor to the person of the new one. This the civilians more usually call succession, as being wholly the work of the law, and to distinguish it from the conventional subrogation, which they also call cession.

SUBSIDY, in law, signifies an aid or tax granted to the king, by parliament, for the necessary occasions of the kingdom; and is to be levied on every subject of ability, according to the rate or value of his lands or goods; but this word, in some of our statutes, is the reference made with that certain persons, to be levied upon account, till their accounts are made up, which is generally once a year, and then they are paid their arrears.

SUBSTITUTION, in the civil law, a disposition of a testament, whereby the testator substitutes one heir for another, who has only the usufruit, and not the property of the thing left him. Substitution is only a kind of fiduciary inheritance, called also idei commissio, in regard the immediate inheritor has only the use or produce of the thing; the body thereof being assigned and appropriated to certain persons, who are likewise to have the usufruit in their turns, but are never to have the property.

Substitution, in algebra, &c. is the putting, in the room of any quantity in an equation, some other, which is equal to it, but expressed in another manner.

SURTANT of a curve is the higher geometry, is the line which determines the intersection of the tangent with the axis; or, that determines the point wherein the tangent cuts the axis prolonged.

In any equation, if the value of the subtangent comes out positive, it is a sign that the points of intersection of the tangent and axis fall on that side of the ordinate where the vertex of the curve line lies, as in the parabola and paraboloids: but if it comes out negative, the point of intersection will fall on the contrary side of the ordinate, in respect of the vertex, or beginning of the abscissa; as is illustrated with the hyperbolic figures. And universally, in all other conic and hyperbolic figures, the subtangent is equal to the exponent of the power of the ordinate, multiplied into the abscissa.

If CB is an ordinate to AB, in any given angle, terminating in any curve AC, and AB = a, BC = y, and the relation between x and y, that is, the nature of the curve, is expressed by this equation, \( x = 2axy + bx^2 - by^2 + cy = 0 \); then this will be the role of drawing a tangent to it: multiply the terms of the equation by an arithmetical progression; suppose, according to the dimensions of y, \( \frac{x^3}{2} - 2axy + bx^2 - by^2 - cy = 0 \)

as also according to the dimensions of x, \( \frac{y^3}{2} - 2axy + bx^2 - by^2 - cy = 0 \)

and the former product shall be the numerator, and the latter, divided by x, the denominator, of a fraction expressing the length of the subtangent; which, in this ease, will be

\( \frac{y^3}{2} - 2axy + bx^2 - by^2 = \frac{y^3}{2} - 2axy + bx^2 - by^2 \)

SUBTENSE, in geometry, the same with the chord of an arc. See CHORD.

Hence, the subtense of an angle is a right line supposed to be drawn between the two extremities of the arc that measures that angle.
Subtraction. See Arithmetic, and Algebra.

Subularia, rough-leaved alison, or arrawort, a genus of plants belonging to the class of tetranymada, and order of silicious; and in the natural order ranking under the 30th order, which the subclass is placed in. The flowers are ovate, concave, and contrary to the partitions. The style is shorter than the stigmas. There is only one species, the aquatica, which is a native of Britain.

Subulated. See Botany.

Succculents. See Succulent plant.

Succinic Acid. Amber is a well-known brown, transparent, inflammable body, pretty hard, and susceptible of polish, bound at some depth in the earth, and on the sea-coast of several countries. It was in high estimation among the ancients both as an ornament and a medicine. When this substance is distilled, a volatile salt is obtained, which is mentioned by Agricola under the name of salt; but its nature was unknown. Boyle was the first who discovered that it was an acid. From succinum, the Latin name of amber, this acid has received the appellation of succinic acid.

It is obtained by the following process: Fill a retort half-way with powdered amber, and cover the powder with a quantity of dry sand; lute on a receiver, and distill in a sand-bath without employing too much heat. There passes over first an inodorous phlegm; then a weak acid, which, according to Scheele, is the acetic; then the succinic acid attaches itself to the neck of the retort; and if the distillation is continued, there comes over at last a thick brown oil, which has an acid taste.

The succinic acid is at first mixed with a quantity of oil. It may be made tolerably pure by dissolving it in hot water, and putting upon the filter a little cotton, previously moistened with oil of amber: this substance retains most of the oil, and allows the solution to pass through. The acid is then crystallized by a gentle evaporation, and this process is to be repeated till the acid is sufficiently pure. Guyton Morveau has discovered that it may be made quite pure by distilling off the insufficient quantity of nitric acid, taking care not to employ a heat strong enough to sublime the succinic acid.

2. The crystals of succinic acid are transparent, white, shining, and of a foliated triangular, prismatic form: they have an acid taste, but are not corrosive: they retain the tint of turmeric, but have little effect on that of violets.

They sublime when exposed to a considerable heat, but not at the heat of a water-bath. In a sand-bath they melt, and then sublime, and condense in the upper part of the vessel; but the coal which remains shows that they are partly decomposed.

3. One part of this acid dissolves in 96 parts of water at the temperature of 30°, according to Sjipeinan; in 24 parts at the temperature of 80°; in two parts of water at the temperature of 212°, according to Storckar de Neuflorn; but the greatest part crystallizes as the water cools. According to Roux, however, it still retains more of the acid than cold water is capable of dissolving.

Two hundred and forty grains of boiling alcohol dissolve 177 of this acid; but crystals again shoot as the solution cools.

4. The compounds which this acid forms with alkalies, acids, and metallic oxides, have received the name of succinates. Scarcely any of them have been examined with attention.

5. When combined with soda, it crystallizes in four and six-sided prisms. When this salt is distilled in a retort, the succinic acid is completely decomposed. There pass over into the receiver an acid liquid, which is the acetic much diluted, and a quantity of brown oil. At the same time carbonic acid gas, and carburetted hydrogen gas, are dispersed, and there remain in the retort soda and charcoal. Hence it follows that this acid, like the others of the same class, is decomposed by heat, and that it is composed of oxygen, hydrogen, and carbon.

6. The affinities of succinic acid, according to Morveau, are as follows:

<table>
<thead>
<tr>
<th>Barytes</th>
<th>Lune</th>
<th>Potass</th>
<th>Soda</th>

Succinum. See Amber.

Sudorific. See Materia Medica.

Suffrance. Tenant at suffrance is he who holds over his term at first lawfully granted. A person is tenant at suffrance who continues after his estate is ended, and wrongfully holds against another, see 1 Co. Inst. 57.

Tenants holding over, after determination of their term, and after demand made in writing to deliver possession, are rendered liable to pay double the yearly value. And tenants giving notice of their intention to quit, and not accordingly delivering up the possession at the time in such notice contained, are rendered liable to pay double rent. And it has been held, that under this act, the notice need not be in writing, and that the landlord may levy his double rent by distress. Bur. 1653.

Sugar, which at present forms so important an article in our food, seems to have been known at a very early period to the inhabitants of India and China. But Europe probably owes its acquaintance with it to the conquests of Alexander the Great. For ages after its introduction into the West, it was used only as a medicine; but its consumption increased very greatly: and during the time of the crusades, the Venetians, who brought it from the East, and distributed it to the northern parts of Europe, carried on a lucrative commerce with sugar. It was not till after the discovery of America and the extensive cultivation of sugar in the West Indies, that its use in Europe, as an article of food, became general.

Sugar was formerly manufactured in the southern parts of Europe; but at present almost all our sugar comes from the East and West Indies. The plant from which it is procured is the saccharum officinarum (see Saccharum), or sugar-cane. Other plants indeed contain it, but not in such abundance. In North America, however, it is extracted from the acer saccharinum, or sugar-maple. Attempts have been lately made to extract it from the beet.

The method of making sugar practised in Indostan is exceedingly simple, and requires little or no expensive apparatus. The soil chosen is a rich vegetable mould, in such a situation that it can be easily watered from above. About the end of May, when the soil is reduced to the state of soft mud either by rain or artificial watering, slips of the cane, containing one or two joints, are planted in rows about four feet from row to row, and eighteen inches in the rows. When they have grown to the height of two or three inches, the earth round them is loosened. In August small trenches are cut through the field to drain off the rain, if the season proves too rainy, and to water the plants if the season proves too dry. From three to six canes spring from each slip set. When they are about three feet high, the lower leaves of each cane are carefully wrapt round it; and then the whole belonging to each slip are tied in strong bundles. These are raised high, and stuck into the earth in the middle of them. They are cut in January and February, about 9 months after the time of planting. They have now reached the height of eight or ten feet, and the naked cane is from an inch to an inch and a quarter in diameter. They have not flowered. When this happens, the juice loses much of its sweetness. The canes are now put through the rollers of a mill, and their juice collected into large iron boilers; where it is boiled down slowly to a proper consistence, the scum being carelessly taken off. The fire is then withdrawn, and the liquid by cooling becomes thick. It is then stirred about with sticks till it begins to take the form of sugar; when it is put in mats made of the leaves of the palma-tree (bozasus stelliformis), and the stirring continued till it is cold. This process yields a raw or powdered sugar; but it is clammy, and apt to attract moisture from the atmosphere, because the acids in the juice have not been removed. By the addition of quicklime to the juice, in the proportion of about three spoonfuls to every gallon of boiling, the sugar may be made to acquire that solid property. The impure sugar prepared by this method is called jagary. Every three quarts of juice, or every six pounds, yields about one pound of sugar. From an acre of ground about 3500 pounds of sugar, and consequently about 30,000 pounds of juice, are obtained.

2. In the West India islands the raising of sugar is much more expensive, and the produce much less, owing to the high price of labour; or, which is increased, to the presence of the labourers, and to the inferiority of the soil. The juice is put into large boilers, mixed with quicklime, and boiled to a proper consistence of the scum in the mean time being carefully taken off. When it ceases to beropy, it is drawn off into another vessel, where it is allowed to concret, and the liquid impure part called molasses to separate from it. The more completely this separation is allowed to be, the better is the sugar. The sugar thus obtained is in small hard grains of a brownish-white colour, and is imported to Europe under the name of raw sugar.

3. In North America the farmers procure sugar for their own use by a still simpler pro-
Sugar.

When heat is applied to sugar it melts, swells, becomes brownish black, emitte-sulphur, and exhaunts a peculiar smell, known to the French by the name of caramel. At a red heat it instantly bursts into flames with a kind of explosion. The colour of the flame is white with blue edges.

6. Sugar, as far as known, is not acted upon by oxygen gas. The effect of the simple combustion it has not been described but it does not appear to be great. Azotic gas or the metals have no sensible actions on it.

The lower compartment of Plate Saw-mill, Sc represents a mill for squeezing the juice from the canes. After Wenzel, a strong frame of wood, the lower part D of which is a large block: the upper surface of this is cut out into a basin, to collect and receive the juice of the canes which is expressed by the three rollers FG, whose lower pivots work in sockets in the block D, and the upper sockets are fixed in the beam E. The sockets of the middle rollers are fixed in the beams D and E. The sockets of the other are held between two wedges cut out in contrary directions, the small end of one wedge being on the same side with the large end of the other. By this means the rollers can always be set nearer together, or farther from each other.

When the juice is drawn near the middle roller, drive out that wedge which is nearest the middle roller, and drive the other in; and the contrary when they are wanted farther apart. The rollers are usually of cast iron, and each end has a cog-wheel, as J, on its upper end, which causes them all to turn together, the power of the first mover being applied to the middle one by a shaft K.

When the machine is in work, a man stands on each side of it. The one in the front takes the cans, and puts them in between the rollers FG, which, as they turn, draw the cans through, and express their juice. The man behind them directs the ends of the cases back between the rollers GI, which are somewhat nearer together than the others; and as they come through, a third man carries them away. The juice runs down the rollers into the reservoir, and is conveyed by a pipe to the boiler D. It must be observed, that the reservoir in the top of the block D must be only cut in channels round the outside of the rollers; being left the full height near the centres, to prevent the sugar running down, and getting out between the wedges ab.

When a sugar-mill is worked by wind, the shaft K is connected with the vertical shafit of the mill. If by horses, the levers they work from are fixed to the shaft K, and either the horse-or the man have ground higher than the trough L, or the juice is conveyed by a pipe laid under the walk.

Sugar-mills that are worked by a water-wheel, or steam-engine, have a beaved wheel fixed on the end of the engine shaft which turns it.

The earth proper do not seem to have any action whatever on sugar; but the alkaline earths unite with it. When lime is added to a solution of sugar, and the mixture boiled for some time, a combination takes place. The liquid still indeed retains its sweet taste; but it has acquired also a bitter and astringent one. A little alcohol added to the solution produces a precipitate in white lakes, which appeared to be a compound of sugar and lime. Sulphuric acid precipitated the lime in the state of sulphate, and restored the original taste of the sugar. When the compound of sugar and lime was evaporated to dryness, a smoke transparent tenacious syrup resulted. A very small addition of sugar and alcohol, the sweet taste is completely restored. When alcohol is agitated with the compound of sugar and potash dissolved in water, it reduces to it, but swells on the top in a state of purity.

The acids are capable of dissolving sugar, and those which are concentrated decompose it. Sulphuric acid very soon acts upon it; water is formed, and perhaps also acetic acid, which is evolved in great abundance, and gives the liquid a black colour, and a considerable degree of consistency. The charcoal may be easily separated by dilution and filtration. When heat is applied, sulphuric acid is rapidly converted into sulphurous acid.

Nitric acid dissolves it with an effervescence, occasioned by the evaporation of nitrous gas, and converts it into malic and oxalic acids. 430 grains of sugar, treated with six ounces of nitric acid diluted with its own weight of water, and cautiously heated, separating the crystals as they formed, yielded 250 grains of oxalic acid; so that 160 parts of sugar yield by this treatment 58 parts of oxalic acid. When liquid oxymuriatic acid is poured upon sugar in powder, it is dissolved, and immediately converted into malic acid; and the oxymuriatic acid is converted into common muriatic acid.

Sugar absorbs muriatic acid gas slowly, and assumes a brown colour and very strong smell. The vegetable acids dissolve it; but seemingly without producing any alteration on it.

The action of the oxides of carbon and azote upon sugar has scarcely been examined.

Sugar is soluble in alcohol, but not in so large a proportion as in water. According to Wenzel, four parts of boiling alcohol dissolve one part of sugar. It unites readily with oils, and renders them miscible with water. A moderate quantity of it prevents, or at least retards, the coagulation of milk; but Scheele discovered that a very large quantity of sugar causes milk to coagulate.

The hydrate sulphates, sulphurates, and phosphates of alkalies and alkaline earths, seem to have the property of decomposing sugar, and of bringing it to a state not very different from that of gum. Mr. Cruckshank introduced a quantity of syrup into a jar standing over mercury, and then added about an equal quantity of phosphorus of lime. Phosphorised hydrogen gas was immediately extracted. In eight days the syrup was withdrawn: it had lost its sweet taste, and acquired a bitter and astringent one (the taste of phosphorus of lime). From this solution alcohol threw down white flakes, very much resembling those of mucilage separated from water by the same liquid. A little sugar was
41 ounce-measures of carbo nic acid gas. The carbo nate hydrogen, according to the ex periments of Goe ring, was composed of five parts carbon and one hydrogen.

These experiments are sufficient to show us, that sugar is composed entirely of oxygen, carbon, and hydrogen. It is of course a vegetable oxide. Lavoisier has concluded, from a series of experiments, that sugars, after fermentation, that these substances enter into the composition of sugar in the following proportions:

<table>
<thead>
<tr>
<th>Oxygen</th>
<th>Carbon</th>
<th>Hydrogen</th>
</tr>
</thead>
<tbody>
<tr>
<td>64</td>
<td>28</td>
<td>100</td>
</tr>
</tbody>
</table>

But these proportions can only be considered as very distant approximations to the truth.

8. From the experiments of different chemists, especially of Proust and Getling, it appears that there are different species of sugar found ready-prepared in the vegetable kingdom; distinguished from each other by the figure of their crystal, and other variations in their properties. The species hitherto examined are three in number, namely, common sugar, sugar of grapes, and sugar of beets. As far as is known at present, there is no difference between the sugar of the maple and common sugar.

9. That grapes contain abundance of sugar has been long known. The Duc de Bouillon first extracted it from the juice of grapes, and Proust pointed out the difference between it and common sugar. The juice of grapes, according to him, yielded from 30 to 40 per cent. of this sugar.

10. Margraf discovered sugar in the root of the beta vulgaris; but it is to Achard that we are indebted for the first attempts to extract it from that plant in a large way. The experiments of that philosopher, of Lampadius, of the committee appointed by the national institute, and of Goebling, have thrown more light on this interesting subject. The method which succeeded in the hands of the last, was to boil the beet-roots (deprived of the heart) till they became so soft as to be easily pierced by a straw. They are then cut into slices, and the juice forced out by pressure. What remains is left for twelve hours in water, and the whole subjected to the press a second time. The liquids thus obtained are filtered through flannel, boiled down to two-thirds, filtered a second time, reduced by boiling to one-third of the original liquid, filtered a third time, and then evaporated to the consistency of syrup. The crystalline crust which forms on the surface is to be broken from time to time, and the spontaneous evaporation continued till the surface becomes covered with a tough coat instead of crystals. The whole is then to be thrown into woolen bags, and the mucilaginous liquid separated from the crystals by pressure.

The sugar obtained by these processes, has much the appearance of raw sugar; but it may be refined by the common processes, and brought into the state of common sugar. From the experiments of Goebling, it appears that the sugar is distinguished by a certain degree of a nauseous bitter taste; owing, it is supposed, to the presence of a bitter, extractive matter, which Lampadius has shewn to be one of the constituents of the beet.

11. The plants containing sugar are very numerous. The following are the chief of those from which it has been actually extracted by chemists:

- The sap of the acer saccharinum, betula alba, aslepias syriaca, hericium spondiulon, cocus nucifera, juglas alba, agave americana, fucus saccharinus, fucus carica.
- The juice of arundo canariensis, the roots of pastinaca sativa, siun sisarum, beta vulgaris and cicis, fucus carolis, aegium pepterniuum.

Parranter has also ascertained, that the grains of wheat, barley, &c. and all the other similar seeds which are used as food, contain at first a large quantity of sugar, which gradually disappears as they approach to a state of maturity. This is the case also with peas and beans, the leguminous seeds; and is one reason why the flavour of young peas is so much superior to that of old ones.

SUIT, in law, is used in different senses, as, 1. Suit personal. 2. Suit of court, or suit service, is an attendance that tenants owe to the court of their lord. 3. Suit covenant, is where the ancestor has covenanted with another, to sue to his court. 4. Suit custom, when a man and his ancestors have been seized time out of mind, of his suit. 5. Suit real, or regal, when men come to the sheriff's tomb or feet. 6. Suit signifies the following one in chase, as fresh suit. 7. It signifies a petition made to the king or any great person. Covel.

SUKOTYRO, a genus of quadrupeds of the order brute; the generic character, born on each side near the eyes. There is but a single species, viz. the indicus··man up right, short, narrow, reaching from the top of the head to the rump. It inhabits Java and feeds on leaves.

SULPHIATS, salts formed with the sulphuric acid, which see.

SULPHITES, salts formed with the sulphurous acid, which see.

SULPHUR, distinguished also in English by the name of brimstone, was known in the earliest ages. As it is found native in many parts of the world, it could not fail very soon to attract the attention of mankind. It was used by the antients in medicine, and its fumes were employed in bleaching wool. See Pliny, Lib. xxxv. c. 15.

1. Sulphur is a hard brittle substance, commonly of a yellow colour, without any smell, and of a weak though perceptible taste. It is a non-conductor of electricity, and of course becomes electric by friction. Its specific gravity is 1.990.

Sulphur undergoes no change by being allowed to remain exposed to the open air. When thrown into water, it does not melt as common salt does, but falls to the bottom, and remains there unchanged. It is therefore insoluble in water.
2. If a considerable piece of sulphur is exposed to a soldering-iron, it will become red without any flaring or volatilization. If a piece of sulphur is heated in a dish to a temperature of about 170° C, it will become red without any flaring or volatilization. If a piece of sulphur is heated in a dish to a temperature of about 219° C, it will become red without any flaring or volatilization.

SULPHURIC ACID is a very important and versatile substance. It is the acid of most importance in the manufacture of many other acids, and is used in the preparation of many important chemicals. It is a strong oxidizing agent and is used in the production of many important chemicals, such as nitric acid and perchloric acid.

SULPHURIC ACID is prepared by the action of water on a red-hot piece of sodium peroxide. It is a strong oxidizing agent and is used in the production of many important chemicals, such as nitric acid and perchloric acid.

SULPHURIC ACID is a transparent, colourless liquid. It is a strong oxidizing agent and is used in the production of many important chemicals, such as nitric acid and perchloric acid.

SULPHURIC ACID is a powerful oxidizing agent and is used in the production of many important chemicals, such as nitric acid and perchloric acid.

SULPHURIC ACID is a very important and versatile substance. It is the acid of most importance in the manufacture of many other acids, and is used in the preparation of many important chemicals. It is a strong oxidizing agent and is used in the production of many important chemicals, such as nitric acid and perchloric acid.
compound of sulphuric acid and lime, subphat of lime, &c.

It absorbs a very considerable quantity of nitrous gas, and acquires by that a purplish colour. Its affinities are as follows:

Barytes, Ammonia,
Strontian, Glaucia,
Potash, Vitriol,
Soda, Alumina,
Lime, Zirconia,
Magnesia, Metallic oxides.

This is one of the most important of all the acids, not only to the chemist but to the manufacturer also; being employed to a very great extent in a variety of manufactures, especially in dyeing.

Sulphuric acid. Though some of the properties of this acid must have been known in the remotest ages, as it is always formed during the slow combustion of sulphur, Stahl was the first chemist who examined it and pointed out its peculiar nature. His method of procuring it was to burn sulphur at a low temperature, and expose to its flames cloth dipped in a solution of potash. By this method he obtained a combination of potash and sulphuric acid; for at a low temperature sulphur forms by combustion only sulphuric acid. Schede pointed out, in 1771, a method of procuring sulphuric acid in quantities. Dr. Priestley, in 1774, obtained it in the gaseous form, and examined its properties while in a state of purity.

1. Sulphuric acid may be procured by the following process: Put into a jar, two parts of sulphuric acid and one part of mercury, and apply the heat of a lamp; the mixture effervescs, and a gas issues from the beak of the retort, and may be received in glass jars filled with mercury, and standing in a mercurial trough. This gas is sulphuric acid.

2. Sulphuric acid, in the state of gas, is colourless and invisible like common air. It is insensible in quantity; put into a dry glass jar, it can animals breathe without death. It has a strong and suffocating odour, precisely the same with that exhaled by sulphur burning with a blue flame: sulphur, by such a combustion, being converted into a sub- phlogistic acid. Its specific gravity, according to Bergman, is 0.00246; according to Lavosser, 0.00251. It is therefore somewhat more than twice as heavy as air. One hundred cubic inches of it weigh nearly 63 grains.

3. This acid reddens vegetable blues, and gradually destroys the greater number of them. It exercises this power on a great variety of vegetable and animal colours. Hence the use of the fumes of sulphur in bleaching wool and in whitening linen stained by means of fruits.

4. Dr. Priestley discovered, that when a strong heat is applied to this acid in close vessels, a quantity of sulphur is precipitated, and the acid is converted into sulphur. Berthollet obtained the same result; but Four- croy and Vauguien could not succeed.

5. Water and salt with avidity. According to Dr. Priestley, 1000 grains of water, at the temperature 54.5°, absorb 30.6 grains of this acid. Fourcroy, on the other hand, affirms that water at 40° absorbs the third of its weight of sulphuric acid gas.

Ice absorbs this gas very rapidly, and is instantly melted. With this, all that remains is a mixture of liquid sulphuric acid, or sulphuric acid, is of the specific gravity 1.046. It may be frozen without parting with any of the acid. When this mixture has been saturated with this acid at the freezing temperature, its specific gravity is equal to 1.0625, and it is filled with a vast number of bubbles, which continuously increase and rise to the surface. These bubbles are a part of the acid separating from it. It freezes a few degrees below 0°.

6. When liquid sulphuric acid is exposed to atmospheric air or to oxygen gas, it gradually combines with oxygen, and is converted into sulphurous acid. This change takes place more completely if the acid is combined with an alkali or earth. When a mixture of sulphuric acid gas and oxygen gas is made to pass through a red-hot porcelain tube, the two bodies combine, and sulphuric acid is formed.

7. Of the simple combustibles, sulphur and phosphorus have no action on it whatever; but when hydrogen gas and charcoal do not alter it while cold, but on being heated they decompose it completely; water or carbonic acid is formed, and sulphur deposited.

8. Neither azeote nor maritiate acid produces any change on it.

9. Sulphuric acid does not seem capable of oxidizing or dissolving any of the metals except iron, zinc, and manganese.

10. It combines with alkalies, earths, and metallic oxides, and forms salts known by the name of sulphates.

11. Sulphuric acid absorbs this gas in considerable quantity. It acquires a yellowish-brown colour, a penetrating odour, and the property of smoking when exposed to the air. When this mixture is distilled, the first vapour which comes over, and which is a compound of the two acids, crystallizes in long white prisms. This singular compound, formerly known by the name of glacial sulphuric acid, is, when the air is dry, a white powder; but when the atmosphere is moist, melts with effervescence. When thrown into water, it hisses like a red iron.

It has the colour of sulphuric acid. The ethics of the court have lately demonstrated, that this is a compound of sulphuric and sulphurous acids.

12. The affinities of sulphuric acid, as far as they have been investigated, are as follows:

<table>
<thead>
<tr>
<th>Barytes</th>
<th>Magnesia</th>
</tr>
</thead>
<tbody>
<tr>
<td>Lime</td>
<td>Ammonia</td>
</tr>
<tr>
<td>Potash</td>
<td>Glaucia</td>
</tr>
<tr>
<td>Soda</td>
<td>Alumina</td>
</tr>
<tr>
<td>Strontian</td>
<td>Zirconia</td>
</tr>
</tbody>
</table>

13. As this acid is formed by the combustion of sulphur, it cannot be doubted that it is composed of the same ingredients with sulphuric acid; and as it is evolved from sulphuric acid by the action of sulphur, and likewise by some of the metals, it cannot be doubted that it contains a smaller proportion of oxygen. But no precise set of experiments has yet been made to determine the proportion of its component parts. Fourcroy affirms that it contains:

| 85 sulphur |
| 15 oxygen |

1000

But he does not inform us upon what evidence he assigns these proportions. SUM, in sums, signifies the quantity that arises from the addition of two or more magnitudes, numbers, or quantities together.

The sum of an equation is, when the absolute number being brought over to the other side of the equation, with a contrary sign, the whole becomes equal to 0; thus, the sum of the equation $x^2 - 12x + 41 = 0$, is $x^2 - 12x + 41 = 0$. See Algebra, and Arithmetic.

S. MACH. See A. Rh. S. See Astronomy. SUNDAY. See Lord's Day.

SUPERcargo, a person employed by merchants to go on a voyage, and oversee their cargo, or lading, and dispose of it to the best advantage.

S. P. S. E. D. A. a writ that lies in a great many cases, and signifies in general, a command to stay proceedings, on good cause shown, which ought otherwise to proceed. By a supersedeas, the doing of a thing, which ought not otherwise have been done, is prevented; or a thing that has been done, is (notwithstanding it was done in a due course of law) thereby made void. 4 Bac. Abr. 667.

A supersedeas is either expressed or implied; an express supersedeas is sometimes by writ, sometimes without a writ; where it is by writ, some person to whom the writ is directed, is thereby commanded to forbear doing the thing thereby directed, or if the thing has been already done, to revoke, as that can be done, the act. 4 Bac. Abr. 667.

Super Statuto de Articulis Cleri, is a law, a writ that lies against the sheriff, or other officer that detain in the king's highway, or in the lands antiently given to the church.

Super Statuto Pacto S. Sch. Et Marshall de Roy, &c., a writ against the subsidy or subsidy, for holding plea of freedom in his court, or for trespass, or contracts not made within the king's house.

Supplies, the sums granted by parliament for defraying the ordinary expenses of the current year. The known or probable amount of the different branches of the year's expences, is stated to the house of commons in a committee of supply, by the chancellor of the exchequer; and after they have been voted by the committee, are formally granted by act of parliament. The granting of the annual supplies as well as permanent taxes, is a peculiar privilege of the house of commons, who never permit any alteration or amendment to be made by the lords, in the bills passed for this purpose.

The grants of parliament were originally considered, merely as temporary aids, to assist the sovereign in defraying such extraordinary expenses as he was subject to for the benefit of the public; and unless the commons happened to entertain at the time, any particular jealousy of the crown and its ministers, the same grants were only left entirely to their disposal. But after the restoration of Charles II., not only more frequent grants were demanded, but, in consequence of the property to which the crown
73 2

this

might be expressed in a more simple form, by
multiplying both numerator and denominator
by that surd which, multiplied into the denominator, gives a rational product thus,
;


\[
\sqrt[3]{20 + \sqrt{12}} + \frac{20 + \sqrt{12}}{\sqrt{5} + \sqrt{3}} - \frac{20 + \sqrt{12}}{\sqrt{5} - \sqrt{3}} = 5 - 3 = 2
\]

\[
\sqrt[100]{2 + 50 + 6} + 6 = 12 + 6 + 6 = 24 + 6 = 8 + 2\sqrt{15}
\]

To do this generally, see Macaulain, lvi. cit. p. 113.

When the square root of a sum is required, it may be conveniently approximated by the root of a rational quantity that approximates to its value. Thus to find the square root of \(3 + 2/3\), first calculate \(\sqrt{2} = 1.41421\). Hence \(2 + 5/6 = \frac{5}{3} + \frac{5}{6}\), the root of which is found to be nearly \(2.41421\).

In like manner we may proceed with any other proposed root. And if the index of the root, proposed to be extracted, is great, a table of logarithms may be used. Thus \(\sqrt[3]{5 + \sqrt{17}}\) may be most conveniently found by logarithms.

Take the logarithm of 17, divide it by 3; find the number corresponding to the quotient; add this number to 5; find the logarithm of the sum, and divide by \(\sqrt[3]{10}\), and the number corresponding to this quotient will be nearly equal to \(\sqrt[3]{5 + \sqrt{17}}\).

But it is sometimes requisite to express the roots of surds exactly by other surds. Thus, in the first example, the square root of \(3 + 2\sqrt{2}\) is \(1 + \sqrt{2}\), and \(3\sqrt{2} + 2\sqrt{2} = 5\sqrt{2}\). For the method of performing this, the curious may consult Mr. Macaulain's Algebras, where also rules for trinomials, &c. may be found.

**SURETY.** In law, generally signifies the same with bail. See Bail.

**SURETY of the peace.** A justice of the peace may, according to his discretion, bind all those to keep the peace, who in his presence shall make any affray, or shall threaten to kill or beat any person, or shall contend together in hot words; and all those who shall go about with unlawful weapons or attendance to the terror of the people; and all such persons as shall be known to him by his common barator; and all who shall be brought before him by a constable, for a breach of the peace in the presence of such constable; and all such persons who, having been before bound to keep the peace, shall be convicted of having forfeited their recognizances.

When surety of the peace is granted by the court of king's bench, if a supersedeas comes from the court of chancery to the justices of that court, their power is at an end; and the parties to as discharged. If security of the peace is desired against a person, the safest way is to apply to the court of chancery, or king's bench. 1 H. 127. If the person against whom security of the peace is demanded is not present, the justice of the peace may commit him immediately, unless he offers sureties; and a constable he may be commanded to find sureties, and be committed for not doing it. 10.

**SURETY of the good behaviour.** Includes the peace; and he that is bound to the good behaviour, is therein also bound to the peace; and yet a man may be committed to find sureties both for the good behaviour and the peace. Dall. c. 129. See Good Behaviour.

**SUREFET.** See Medicine.

**SURGERY.** is the art of cutting or alleviating diseases by local and external applications, manual or instrumental. As a science it may be defined, that department of medicine which treats of maladies thus susceptible of alleviation or cure.

This, like other parts of medicine, must necessarily have been practised in the medical writers of the antients; and hence the authority of history, both sacred and profane, that the whole of the healing art was for some time restricted to the treatment of external injuries; and that consequently, surgery has not merely been coeval with, but antecedent to, the other branches of medical science.

The history, however, of surgery, among the early Asiatics, and even as cultivated and practised by the Greeks, is involved in fable, and obscured by fiction. Hippocrates was in a manner the founder of surgery as of medicine; and it was not indeed until after the time of this author, that the science was divided into separate branches. This division was effected in the time of Ptolemy Philopator, king of Egypt, and has continued with some modifications, but without precise limits, down to the present day.

Among the Romans, Celsus is the first author, in whose writings we meet with any account of surgery. The first of the antients, whose works were exactly translated into this art. In the works of Celsus, we find a minute statement of all its improvements, from the time of Hippocrates; and by many among the moderns, an examination of the works of Celsus, has been earnestly recommended to the student. The Latinity, however, of this medical classic, is greatly preferable to his surgery.

After Celsus, lived the celebrated Galen, whose authority for so long a period influenced the language and practice of physic, and who, although his works are principally medicinal, wrote likewise on surgery. Galen was the last writer of consequence among the Romans.

About the year 500, Aetius added many observations to those of Celsus and Galen. Aetius was succeeded and much excelled by Paulus Egucera, whose surgical writings have been pronounced superior to those of all the other antients; this last author, together with Celsus, were employed as text-books by Fabricius ab Aquapendente, a writer of celebrity in the sixteenth century.

Among the Romans and Asiatics, Fabricius and Avicenna are the principal writers who treated of surgery. The Canon Medicine of the latter, a compilation principally from Galen and Rhazes, was for a number of years held in such estimation, that it was not, however, until the time of Albucasis, that surgery was much in repute among the Arabs; and from this period to the 14th century, its history is extremely barren. Even at the commences of the 16th century, "surgery was held in contempt in this island, and was practiced indiscriminately by barbers, farriers, and surgery-gilders. Barbers and surgeons combined for 200 years afterwards to be incorporated in one company, both in London and Paris. In Holland and some parts of Germany, even at this day, barbers exercise the razor and lancet alternately."

We find no surgical work worthy of notice in the history of Celsus. A system published by the above-mentioned Fabricius, shortly afterwards attracted much notice, and has been highly commended by Boerhaave; about this time likewise, a French surgeon, made several bold and very important inno-
anatomy, structure, relative connections, and functions, of the parts concerned; for the sword or the bullet may, by the smallest diffe-
rence in its effect, occasion continuo-
us death; give rise to tedious, intractable, and ultimately fatal diseases; or penetrate and even pass through the body, almost with im-
punity.

Wounds of the breast and lungs. Extreme difficulty of breathing, coughing up of blood, a discharge of air from its external orifice, or the sudden formation of emphysema or windy tumour, &c. are described by authors, among the signs indicating a wound in the thoracic substance. If, together with these symptoms, "the patient is oppressed, tossing, insen-
sible; his face ghastly, and his extremities cold; his condition is doubtful; it looks much like a wound of some vessel near the root of the lungs, and if so, he is surely gone. If the oppression comes on more slowly, the pulse only hurried and fluttering, and the extremities not so cold, there is reason to hope that though it is merely in the edges of the lungs; and as it is at a distance from the great veins and arteries, he may escape."

(J. Bell on Wounds.) If, when the breast is wounded, there is no emphysema, no splitting of skin; indeed, of that of the skin, an inspection, which proves that the blood is pouring either into the proper air-cells of the lungs, or the cellular texture of these organs, it may be concluded, that the wound-making instrument has not passed into the thoracic cavity, but is merely in the external part of the chest. To ascertain whether the suffocative oppression just noticed, proceeds from extravasation of blood into the air-cells, or merely into the thoracic cavity, we are directed, that the finger be thrust into the wound, and some blood let out; which opera-
tion, if it is attended with very sensible relief, proves, that the air-cells or proper cavity of the lungs are uninjured; and the danger in this last case, it much less than if these cells had been wounded.

Wounds of the belly. Wounds of the belly are for the most part mortal; and this, when it does not arise from an injury to any of the great vessels or great organs, principally depends upon the extreme suscepti-
bility to peritoneal inflammation. "Wounds of the head are deadly, from the oppression of the brain, and there delirium or coma are the characters. Wounds of the breast are fatal by the oppression of the lungs; and there difficult breathing, tossing, coughing of blood, coldness of the extremities, and a fluttering, pulse are the mortal signs. Wounds of the abdomen are mortal by the inflammation and gangrene; and the signs of danger are, swelling of the abdomen, intense pain, vomitings, costiveness, hiccup, faint-
ings; then an interval of deceptual case, which is merely a sign of intellectual gan-
grene, and of the near approach of death. The wound-making instrument, however, may penetrate or pass through the liver or the spleen, and prove mortal in another way be-
side that of inducing peritoneal inflamma-
tion; viz. by occasioning a sudden and co-
pious extravasation of blood, and in these last cases the fatal symptoms present themselves with more rapidity. In wounds of the liver, the patient immediately sinks; and faints, languishes in a slumbering state, insensible almost and without pain, lies cold and dead-like for perhaps twenty-four hours, and then ex-
pires."

When the spleen or vena cava is wounded, the signs and consequences of the internal bleeding are nearly the same as in wounds of the liver. "A wound," says Mr. J. Bell, "of the spleen, liver, or vena cava, is as deadly as a wound of the heart, so full are they of blood." To this rule, however, there are some very few exceptions.

The inward bleedings from smaller vessels, as of the mesentery, the kidney, the emul-

gent veins, &c. for the most part prove mortal, in the secondary manner above allu-
ded to, viz. by inducing inflammation; in these last instances then, the progress and nature of the symptoms are different. "And here it may be noticed, that if there are immediate fainting on receiving the wound, and coldness, accompanied with a con-
tinued fainting, swelling of the belly, and oppressed breathing, most likely there is blood extravasated, and in dangerous quan-
tity, from the great vessels; but if the patient has lain easy, and there come pain, swelling, fever, and other threatening signs on the sixth or seventh day, with a tumour in one part of the belly, it is most likely a bloody peritonitis has begun to exist by that inflammation. If there are pain and swelling on the first or second day, it is from wounded intestine; if there are pain and swelling, but not till the sixth day, it is from blood; if there be no pain, the patient dies on the fifteenth day, our patient is almost safe."

When the stomach is wounded, a burning sensation is experienced at the pit of this organ, then follow heat, thirst, an acceler-
ate pulse, and violent vomiting, which are succeeded by fainting, extreme prostration of the vital powers, an extremely rapid and fluctuating pulse, swelling of the abdomen, hiccup, and death.

If the wound is in the intestines, the faces often escape from the orifice; fever, pain, irritable pulse, swelling of the belly, faintings, mortification state.

We have hitherto spoken of peritonitis inflammation, as occasioned by an extrav-
asation of blood; frequently, however, the irritating cause by which it is induced, consists of the viscera or viscid matter that may be wounded. Thus, when the gall-
bladder is the seat of the injury, the bile is poured out; when the urinary bladder is wounded, the urine; when the stomach, the food; and when the intestines, the faces are discharged, and excite this fatal inflammation.

It is scarcely necessary to add, that be-
side the symptoms already enumerated, jaun
cicle will almost invariably be attendant upon a wound of the gall-bladder or ducts; and an incontinence or suppression of urine, of the urinary bladder.

Further, a large wound penetrating the cavity of the belly is generally attended with a protrusion of some of the viscera; and even when the wound does not penetrate through the
dominant cavity, the peritonitis sometimes protrudes and occasions hernia. Wounds likewise of the belly, which do not pierce the cavity of the abdomen, often prove dis-
abling to those whose condition is the most fatal, by occasioning serious ulcers among the mus-
cles, and caries of the bones, and hectic fever.

This is frequently the case in gun-shot wounds, where, the bullet being lodged about the loins and in the heart of the muscles, the patient may have escaped the first danger, and yet, by the constant and fatal action of the victim of tedious suppurati on, and lingering wasting hectic.

Respecting the symptoms which succeed to injuries of the head, we shall defer our remarks till we come to notice the surgical operations on the skull; and shall now go on to consider the treatment of wounds.

Treatment of wounds. It will first be ne-
cessary to consider the management of what are called simple wounds, without supposing the injury to have extended to the internal organs; to state the circumstances which may interfere with the orderly course of healing of such wound; and then to notice the more particular treatment of wounds in the breast or belly.

In conducting the cure of simple wounds, the surgeon will find "his duties happily reduced within the narrowest bounds, viz. of saving the patient from immediate bleed-
ing, and of laying the wounded parts so clearly, so neatly, and so evenly in contact with another, that the rest we leave to nature." "I fear," says the author from whom we have taken the above extract, "that from my announcing a rule of conduct so simple as this is, you will sup-
pose, that I mean to speak only of the slightest and more trivial wounds; while I do really mean to include, under this general view, the greatest and the smallest wounds; and to establish but one rule for all, from the ampu-
tation of a limb, or the extirpation of a tu-
mour, to the most trivial cut of the cheek or hand.

"What is amputation but a wound? the greatest wound, clean and fair, made care-
fully by the hand of the surgeon, disposed to heal in the easiest way; and in this great wound, which a fortress includes the doctrine of every lesser wound, what is there to at- tend to but the procuring of adhesion, or the stopping of the flow of blood? What were we told concerning the amputation of a limb that the surgeon knew not how to procure this adhesion? that he had no means by which he could stop the bleeding? The lambrorrhage fatal to most of those who needed to suffer this operation; and the few who sur-
vived lingered through all the miseries of a nine-months cure, tedious and imperfect, with conical, ulcerated, and tender stumps. What indeed is the chief perfection of modern surgery, or the excellence of our operations, but that in bleeding from great vessels we trust nothing to compression, cauteries, or astringents, but tie our arteries firmly; and that we talk no longer about muddying, the edges of a cut, or clearing away the fat of the wound. We never dress the cut surfaces as distinct wounds, but put the sides or lips in close contact, and keep them so. We boast no-	hing of our own powers, but trust all to na-
ture; whose business it is, to make those sur-
faces adhere which will adhere; or reunite by the slower process of suppuration and granulation, those parts among which there has been a loss of substance." (J. Bell on Wounds at other times, however, some months after.)

We have thus taken the liberty of copying the masterly and impressive language of this
ed or hair-lip suture, from its being principally had recourse is in order to unite the cut edges of a hair-lip. The manner of using this suture is the following: The broad edges of the wound are brought as nearly and neatly as possible in contact, and transfixed with the needle employed for the purpose. In the hair-lip operation, two of these pins are inserted, one at the edge of the lip, and one in or above the middle of the cut; we then twist a thread from one to the other pin, in the form of a figure of 8. (See fig. 9 in the Surgical Plates.)

In long and deep wounds among muscular substance, stitching will generally be requisite, and in proportion to their length must the stitches be multiplied. We are commonly directed by authors to make “for each inch of the wound, one stitch of the needle,” passing, according to the extent of the wound, so many separate ligatures, which, after being all passed, are to be tied each over the surface, first by a single, then by a slip-knot. In this manner is the interrupted suture of the antients formed; which they distinguished from the continued suture, from the latter the suture is made, and the edges are sewn all along the wound. In each interstice of the interrupted suture, it will be necessary to lay one strip of adhesive plaster.

When the wound is still deeper, so that the stitches cannot go to the bottom, the compression, and what is called the uniting bandage, must be applied after stitching. This is formed by putting a double-headed roller round the part, passing one head through a slip in the bandage round the roller at once.

"If the wound is pretty deep among the muscular flesh, so that the several stitches of the interrupted suture would make (if tied by the common knots) an awkward and painful suture, likely to excite inflammation, we then convert the interrupted suture into what is called the quilted suture; which is made by splitting each end of the ligature (after the stitches are made) into two threads; then laying a quill or bougie along each side of the wound, we tie all the ligatures each side round one bougie; then draw that bougie tight down, by pulling the ligatures from the other side; then tie the ligatures also on the other side, round the opposite bougie; so that the two bougies, like two large rolls, keep the sides of the wound neat and even." This suture is not often employed.

After describing these different methods of effecting union between the divided edges of a wound, it is necessary to caution the reader further against using them indiscriminately in very deep muscular wounds. "Stitches after all can support only the edges of the wound, while it is the compress and the uniting bandage that must support all below." Thus stitches carried to a great depth have not only failed of their object, but have too often been the immediate occasion of convulsions, inflammations, and their long and dreadful train of consequences.

Stitches must also be employed cautiously if the patient, previous to the accident, has suffered from slight inflammation, or has been exposed during the cure to the contaminted and deadly atmosphere of a crowded, filthy, and unventilated hospital.

With respect to the manner of arresting the bleeding, when one principal, or several ramifications of an artery are divided in a wound, so that profuse hemorrhage takes place, the application of the tourniquet (fig. 10) is called for. The arteries are afterwards to be taken up, and secured in, the following manner: The tourniquet is so long little loosened in order to discover the artery, which makes a noose on the ligature to be employed: this being placed over the tuniculum (see fig. 11), the sharp point of this instrument is passed through the sides of the artery vessels and wound of it taken out from the surrounding flesh, as is sufficient to afford surface for a secure knot, which the assistant makes upon it.

If, from the depth of the wound, the tension has relaxed, the crooked needle is to be employed instead; and it is to be passed under the artery, as little of the muscular substance as possible to be included in the ligature. If the artery to be secured is superficial, and lies against bone, as in the temple, in the hand, or the forearm, it may be secured by a firm compress. If it is convenient to make this compress within the wound, it may be formed of a piece of sponge, cork, folded leather, or linen. Such application will necessarily for a time interrupt the cure by adhesion.

When the wound has been sewed, the ends of the ligatures that are round the arteries are to be left hanging from its corners.

Such then is the immediate business of the surgeon, viz. to arrest hemorrhage; and to bring out as speedily as possible the divided edges of the wound into contact, in order to secure the commencement of that adhesive process already spoken of. But with the closing of the wound, the surgeon's business is not finished. For the part, indeed, if the junction has been duly effected, if the patient is in health and properly managed, a certain degree of union will be shortly formed, the ligatures that have been employed will come away on the fourth or fifth day, and the adhesive action that is going on will not amount either to actual inflammation (although it is called the adhesive inflammation), or be accompanied by any systematic irritation of capital progress, however, of cure, in all wounds that have been closed by ligature, some degree of actual inflammation is always produced; and for this reason, that the ligatures themselves cannot but act as local irritants. Now if the tendency in the system is to inflame; if the stitches have been carried too deep, or the ligatures are too tightly pulled; if there is blood poured out under the skin, by which it is separated from the parts below; if, in a word, any cause has place of either generation or undue irritation; instead of the kindly progress of this adhesive natural and healthy action, pain, inflammation, and swelling of the parts, will ensue and if this arise to any extent, "you must immediately undo your bandage, draw out your pins, or cut your stitches, and take away every thing that is like structure upon the wound; these sudden occurrences may abate the ensuing inflammation, and prevent the total separation of the skin; while you may still endeavour to keep the wound tolerably close by the more gentle means of sticking-plasters."

"But should the inflammation rise still higher, and should you perceive that a total
Surgery.

If gun-shot or bruised wounds cannot be made to heal directly, or by adhesion, it follows that the treatment will have to be found in some measure peculiar; we are, therefore, now to discuss the question of such peculiarity, and in so doing we shall for the present limit the consideration of wounds which have not penetrated the thoracic, or abdominal cavities. The symptoms of wounds in the breast and belly, we have already enumerated; on their management, medical and surgical, we shall shortly enlarge.

Treatment of gun-shot wounds.

In gun-shot wounds which have neither penetrated the two great cavities of the chest and abdomen, nor have been made upon the head, the principal points of consideration are; the direction or place of lodgment of the ball, whether one or more bones have been splintered or broken, whether any considerable artery has been torn up, whether the wound has reached any of the joints, and lastly, by what means any foreign matter, such as the patient's clothes. These points are to be determined by an acquaintance with the anatomy of the parts; by probing, scarifying, or dilating the wound; and the surgeon, from the marks taken of the symptoms which the injury has occasioned.

"All probing should be done at the time of the wound," while the parts are still by the finger, and be gentle. The irritation and inflammation have come on. The finger is the best probing-instrument; "it is not apt to catch upon tendons or nerves; it does not so much as the probe endanger the arteries; and by feeling with the finger, we judge most accurately of the condition of the wound. The finger both directs our operations, and instructs us what is to be done. Perhaps we feel the ball, and then we cut directly upon it; perhaps we feel the wound making a crooked or spiral turn, and we follow it with our incisions; perhaps we are sensible that it touches a great artery, and in working with our bistoury we are careful of that artery; or we know that there is a splinter in a joint, or broken any bone; accidents which not only increase the danger, but which may even incline us in certain circumstances to cut off the limb. In short, all that we receive, is from the information that we have through the finger, and it directs all our operations."

What are these operations? Either to scarify or dilate the wound, as circumstances demand, to make a counter-opening when necessary, and to extract balls, clothes, or splinters of bone. The purposes of scarifying are, "to open the vessels that they may bleed, to enlarge the wound that when it inflames it may have room to swell," and to enable the surgeon when requisite to take up the bleeding vessel, and expel the ball, the splinters of bone, or any other foreign and irritating material.

Every gun-shot wound which is deep and penetrating, with a narrow opening, and with a tense fascia (ven if no foreign body is to be extracted), requires immediate scarification; the incision, it must be carefully remembered, is "to pass through the fascia as well as the skin; the wound must have vent, as the older surgeons were wont to express themselves, in other words "it must have room to swell" during that inflammation which inevitably precedes its cure. The incision, as in strangulated hernia, must be taken off. So far then all is plain and simple. But the practice is too often in the cure of such wounds not so. Counter-openings are sometimes made, or splinters, or other foreign matters are to be searched for and taken out, and great vessels to be secured. When the ball has passed entirely through which it has formed by its exit is called the counter-opening; when it has passed a considerable way, but not entirely through, it becomes the business of the surgeon to make this counter-opening in order to extract the ball. This practice is advised by the generality of surgeons; "when the ball has only passed two-thirds through the limb." Such direction is for the most part to be followed, and the operation should be performed as speedily as possible.

But there is also another kind of counter-opening, which is especially attended to, which the surgeon is at times obliged to practise. The opening which he must afterwards make in the middle of a long wound, when the track of the wound swells, or when the ball leaves the skin, or molten, the sloughs, and the fistulous, seem to be confirmed. For example: a man is wounded by a ball, which breaks one or two of the fingers, pierces the hand, runs up the fore arm, rakes along the bones, and goes out far from its entrance, as at the elbow or shoulder-jooint. Here we can hardly prevent a long suppuration, and too often an exfoliation or spoiling of the bones; and three openings are required; one where the ball entered, another at the counter-opening or that by which the ball passed out, and if the swelling, pain, irritation, or perhaps nervous symptoms, come on, then there will be required also another opening in the middle of the wound. Such an opening will ease the swelling, and prevent a suppuration of the wound. It will prevent gangrene, bring on a good suppuration, and allow a free vent for the matter; it will also prevent the pus from lying in the arm, and it will save us from the severe or rather cruel practice of the older surgeons, who were accustomed, in such cases, to run a large septic through the tube of the longest wound. To make this opening deeper when the wound has become entirely callous, and pours out a thin gleydis discharge; or when, from the adherence of some piece of cloth which prevents its healing, healthy action cannot otherwise be expected.

So far then with respect to the scarifications which are required in gun-shot wounds; we now proceed to treat of the extraction of balls, cloth, or splinters of bones.

Here dilations rather than scarifications are useful: for there is this difference between scarifying and dilating; that scarifying is that same practice which we perform in the mouth of the wound by which we relieve the tension of the fascia or the structure of the skin; but dilating is that deeper incision which we make by pressing our finger deep, and to the bottom of the wound, and pressing it with the bistoury, to make a free way for getting at the bleeding artery, or extracting the fractured bone. When we wish then to extract the ball, we are to employ free incisions.
The fingers are to be used more than the forceps; these when the ball is found are to be introduced, and made to grasp it. Sometimes the ball will have been stopped by a bone and flattened, with a splintering or splintering of such bone; at other times, however, the bone by the force with which the ballhas struck it will be shattered: in this case the splinters of bone are to be all carefully taken out, and the ball removed as of fractured bone. If the ball has entered and sticks in the bone, so that it cannot be extracted in the common way, then a more free incision must be made, and the trepan applied; "or if it is a narrow and firm bone, Mr. L. was ordered to cut the bone burrow above and below, so as to cut away that part in which the ball is fixed."

But it is principally on account of fractured bones, wounded art-ribs, or pieces of cloth, that these dilatations of a wound are called for. It is only the openness of the wound, and the nearness of the ball, that tempts us to search for it; for a bullet sometimes works its way outward through the cellular substance, and comes to the surface with little pain, or often it lies without danger buried in the flesh for years. If there be another occasion for opening the wound, we should never give the patient pain on account of the ball, since it seldom itself gives him pain."

It must, however, be carefully kept in mind, that wounds, even though fair and promising for a short time, will never heal kindly while the foreign matters above-mentioned are suffered to remain. When there is much blood spouting from a gun-shot wound, it will be concluded that a great artery is involved, and if the patient is a case for a surgeon, guided by his knowledge of the anatomy of the limb, will make free dilatations from the mouth of the wound, until he finds the vessel, which he will tie up or secure. He must not, however, if the bleeding artery is of a large size, trust to compress or bandage. A piece of lint dry, or with some simple ointment, is then to be laid over the orifice of the wound, its sides are to be brought as possible, without occasioning much irritation, and adhesive plaster or bandage to be placed over the whole. But there is another kind of hemorrhage from gun-shot wounds still more dangerous, which is the secondary hemorrhage. This often occurs eight or nine days after the injury was first received, and the patient has often fallen a victim to it, even when "at the first the wound was scarcely stained with blood." This hemorrhage is occasioned by the loosening of the eschar of the mortified and bruised parts, leaving a breach in the sides of a great artery. In the course then of healing a wound, the proximity of which to a considerably artery is known, the patient ought to be attentive and incessantly watched: and in some cases it is necessary to keep constantly a tourniquet round the limb.

We conclude this part of our subject by repeating the motives for sacrificing and for diluting gun-shot, as well as the necessity for the purpose "of opening the vessels that they may bleed," and in order thus to reduce the wound as nearly as may be to one made by a cutting instrument. The dilatation of a wound is for the purpose of enabling us to secure any great artery that may have been divided, and to extract splinters of bone, or any other foreign material, the ball itself being that which, on account of its shape and smooth surface, we are the least solicitous.

Of tubular or penetrating wounds.

But there is further another kind of wound which is different in its nature and treatment from that made by a plain and fair division of parts, viz. a penetrating or tubular wound, such as is made by the bayonet or sword; and in this last case it is the surgeon's duty to bring it as much as possible into that condition in which its sides may, by being applied to each other, adhere. "Suppose," says Mr. J. Bell, "a young man is fighting a duel with the sword, is wounded in the sword arm, his antagonist's weapon goes in at the wrist, and out at the elbow. If in such case it injects the arm with blood, forming a proper aneurism, so that we are forced to cut up the fore arm, and tie the wounded artery; but if it is merely a flesh wound, it is no worse than being deep and penetrating; but still it is so different from a common and open wound, that we could bring the sides of this tube-like wound fairly in contact with each other, it is the more uncertain that it does not happen so is plainly this, that the blood which exudes from the very small arteries is sufficient to fill the tube of the wound: it only fills it, but the bleeding practice followed by a compress and close bandage from getting out, the tube of the wound is not only filled but diluted with blood, and therefore cannot adhere, just for the same reason as the healing of an illapatant stump is delayed because where the arteries, not being fairly tied, have bled after the dressing so as to fill the basin of the stump, and separate the flaps from each other. This not only prevents adhesion and brings on suppuration, but produces a gangrenous stump filled with foul and stinking matter, partly purulent, and partly filled with blood."

The obvious inference from all this is, that the best practice in each of which we are now speaking, is principally to be facilitated, nay, is alone to be effected, by cleansing it of this blood (when no important artery is divided), by closing the mouth of the wound with a slight compress, and "laying its sides together with a slight bandage." It was in thus cleansing these wounds of blood previously to closing them, that the remarkable success attended what was denominated some time ago "the secret dressing," this used to be performed by men who were denounced suckers, one of whom was present at every sword-duel. "The encounter ended the instant that one of the combatants received a wound; the sucker immediately applied himself to suck the wound, and continued sucking and discharging the blood till the wound ceased to bleed; and then, the wound being clean, he applied a piece of chewing paper on the wound, tied up the two with a tight bandage, and then the patient walked home."

This mode of treatment has proved successful even in wounds which have pierced, or passed through, some of the cavities, when there have been no veins, nor any great blood-vessels wounded.

In a deep and penetrating wound, therefore, the method of cure consists in purging it of its extraneous load, and conveying its sides to adhere. We do not here need to make incisions or scarifications, as in gun-shot wounds, unless for the purpose of securing some great artery that may have been divided.

Having thus gone over the surgical treatment of wounds, fair, angular, bruised, lacerated, and penetrating, we now proceed to lay down some rules respecting the medical management of patients under these injuries, and which is still more important than the surgery itself of wounds; "for if the connection is not understood between the particular wound and the general health; if the army or hospital surgeon (and the same remark applies with modifications to private practice) does not know with a glance the constitution of a patient, or the true state of his sore; if he is not careful to retain some general principle, which, like a mystic clue, may lead him through this labyrinth, he will see thousands dying around him without knowing the cause, like the fables of the Greek camp falling under the invisible shafts of Apollo."

Among the very many mistakes and unmeaning prejudices which have crept into the practice of both medicine and surgery, that of indiscriminate blood-letting has, perhaps, proved the most pernicious. This practice, so long held up, as it is now shown can possibly be more preposterous, or more dangerous. The writer of this article not many days since heard of an instance (an extreme case it must be confessed, yet, as such, more especially illustrative of the injudicious conduct now referred to) of a superannuated lady, by some accident having been literally scorched to death; the surgeon who was summoned found himself preceded by another "practitioner," who was actually, while the writer's friend entered the room, unheathing his lanceet in order "to take some blood." In like manner, with more colour of propriety, it must be admitted, when a wounded patient is first brought in, and the doctors are called, numbers, even to this day, deemed a necessary preliminary to further proceedings, to bleed the patient. "The sovereign cordial of the landlady" is often more appropriate; and many lives have, perhaps, been saved by the absence of the village surgeon.

Let the following invariable rules be treasured in the mind of the young practitioner, not as dogmas to force, but as principles to regulate, his practice. They are more directly drawn up for the use of army and navy surgeons, but will be found highly important to surgeons in general.

1st. "When your wounded patient is first brought to you, he is in great confusion; there is a tremor, a tonic stiffness, or almost a convulsion of the whole frame; there are coldness, fainting, and nervous affection; but it is merely a nervous affection, and it must be treated as such. You must expect it to subsist in time, and therefore should give him a good warm cordial, and large opiates to quiet the commotion. This is no time for bleeding, whatever the nature of the wound may be. If the stupor continues, you should give commulsions, draughts, and wine."

Vol. II.
2d. "If this nervous commotion being quieted, a sharp fever should come on, still do not bleed, but rather be upon the reserve; for perhaps this, which at first seems to be a pure inflammatory fever, may turn out to be a fit of an ague, to which the patient is subject; it is therefore a low and malignant fever; it may be an attack of some camp disease; and if a diarrhoea, great weakness, and low musing delirium, should come on immediately after you have bled your patient freely, there is no doubt at all of what you had done, and you would indeed have much to answer for.

3d. "Reserve your bleedings for those more dangerous cases, where high inflammation is so often fatal, and do not bleed in wounds of the lips, shoulders, or limbs. Reserve bleeding for wounds of the breast or belly, or great joints; for in all wounds of cavities, inflammation, which can hardly be escaped, is the great danger.

4th. "If a man is wounded after a full meal, there can be no doubt that a gentle vomit will be most useful, where it is allowed by the circumstances of the wound. The old physicians found their advantage in it, and ascribed the good effects of vomiting to the preventing of crude and ill-concocted chyle from entering into the system, so as to kindle up a fever. There is no doubt that a meal which was no load during health, will be a great oppression upon a disordered system, and the carrying it off must be a great relief, although the old physicians, by talking this useless jargon about ill-concocted chyle, might almost provoke us to reject both the doctrine and the practice. The system cannot be weakened by a gentle emetic; and if the system should fall low after vomiting, it were easy to substitute a fitter support, and better excitement, than that of an oppressed stomach and loaded intestines, by first discharging these crude meats, and giving, when the stomach was emptied, food of easy digestion, and cordials suited to the condition of the system.

5th. "But in every wound there comes a period of weakness, in which we repent of every thing we have made, even when it was really needed; a period in which, by confinement and pain, occasional fever, diarrhoea, profuse suppuration, or colliquative sweat, the patient falls so low that it is not easy to support him through the cure: and thus there are two great principles in the treatment of gun-shot wounds: that even at first we should be sparing of blood; and that the period of weakness which is to succeed, is the great danger; on this single point hangs all the practice.

The author afterwards adds, that in mere flesh-wounds we are not entitled to bleed; for if there is no wound of a joint, or fractured bone, the first inflammation never runs to a crisis.

By due attention to the above rules, the surgeon will never find himself at a loss with regard to the immediate requisitions of the wounded, either in army, navy, hospital, or private practice. It will scarcely be necessary to observe, that where immediate bleeding is judged necessary (and this is always the case, as above stated, in wounds of cavities and joints), it may be employed most freely in the young, full-fed, vigorous, and phthisic, in dry and healthy situations, in the spring of the year, when no epidemic disorder prevails, and when the patient is afterwards to enjoy all the advantages of cleanliness, air, and a suitable diet.

In the progress of the cure, the surgeon is still not to lose sight of the intimate connection between the condition of the general system, and the state of the wound. Still fever is to be distinguished from inflammation: and the two opposite kinds of inflammation treated of in the article Medicine, vol. ii. p. 230, are likewise to be sedulously discriminated: the one will require a low diet, evacuating medicines, and, as it is expressed, a cooling antiphlogistic regimen; the other as loudly calls for bark, wine, opium, elixir of vitriol, and above all pure air, and (so as not to overload or oppress the weakened organs of digestion), rich or rather nourishing food. Here, instead of further reducing the system, "you must trust to air and cleanliness, and bark and wine."

We now proceed to speak of the treatment of wounds in the two cavities of the chest and belly.

The first and great danger in a wound which has penetrated the thoracic cavity, is that of suffocation from blood poured into the air-cells, or towards the trachea. The first and principal object then of the surgeon is to obviate this consequence as speedily as possible; and here immediate and sometimes frequently-repeated bleedings are called for, even should the patient be in a condition unfavorable to the discharge of blood. To this end, it is your duty to keep the patient low, and to drain his system so thoroughly of blood, that none shall pass towards the lungs to suffocate him, and that there may not be blood enough in the system to serve as fuel for that inflammation which sooner or later must come on."

When the blood is merely poured into the cellular membrane or cavity of the breast, without entering the air-cells, the finger, as already mentioned, is to be introduced into the wound; or if this wound is too high for the necessary discharge of the extravasated blood, a fresh wound may be made lower down upon the breast, and this so that the surgeon may find it in his power to reach and tie the intercostal artery, if this artery has not been divided.

For the emphysema or windy swelling, which is often so alarming to the bystanders, but which is in reality the most trivial symptom, scarifications are to be made in order to discharge the collected air.

If, during the cure of a breast-wound, there comes on a pricking in the side; if the cough is aggravated, or the putrid matter comes more copious, and the systematic irritation increased, there will be reason to suspect the remains of some irritating material, as a splinter of bone; in this case, the wound is to be probed, injected, and every endeavour made to extract the irritating cause.

"Sensible, at every turn, how slight a matter will irritate the pleura and lungs, the surgeon will never allow himself to do so unnatural a thing, as to cut into the pleural cavity across the chest, when this is thus easily irritated by the most trifling piece of bone or rag of cloth; but he merely lays a bit of oiled cadis gently within the wound, with a large emollient poultice over all."

To conclude. In the wounds we are now describing, the surgeon must in the first day bleed copiously, and repeatedly; he must again bleed should bloody expectation recur, weakening the system in order to prevent the lungs from being shut up with the air; of which the oppression is forgotten, and the danger of suffocation, and the bleedings from the lungs, are over, he begins to support his patient's strength with opium and bark, and promotes his health and strength.

Wounds in the abdomen. While the danger from wounded lungs is chiefly of suffocation, in wounds of the abdomen, as before stated, we have principally to fear either sudden death from internal hemorrhage, or peritonitical inflammation, when the bleeding has been too profuse. Against this internal bleeding, bleeding from the ari is the great preservative; and this, as in wounded lungs, must be done with a very liberal hand. When the peritonitical inflammation has come on, the patient must be assiduously preserved from all motion and irritation; oysters of a mild gentle kind must be injected, the belly forment, and opiates administered.

No food is to be given for the first ten or twelve days; nourishment is to be conveyed by elysor, or if any thing is taken by the stomach, it must be extremely mild and gelatious. If the wound has not penetrated the intestine, but part of the sound gut is protruded, it must be gently returned with the finger, and the outward wound stitched over it.

When, from the passing out of the faces, it is evident that an intestine is wounded, this is not to be searched for with the finger, but suffered to remain; and from the universal pressure among the parts, the outward and inward wound will be brought opposite to each other. If, however, the wounded intestine is protruded, it is to be connected by a single stitch to the external wound, in order that the faces may be thrown out from this line, and the adhesive process encouraged.

When, through a narrow wound, a sound bowel is obstrued, and becomes inflamed, this pressure is to be relieved by opening the wound a little wider, the intestine is to be carefully returned, and then the outer wound stitched.

Before we quit this subject of wounds, an apology may be thought necessary for enlarging disproportionately on this division of the article. We have done so for the purpose of illustrating the advantage that practical surgery has received from the natural, as opposed to the artificial cure of wounds, of which the learned author will find it necessary to impress on his mind as a directory in every step of his practice, whether operative or medicinal. We shall conclude this section by an extract from an author to whose incomparable treatise on wounds we have been principally indebted for what information the preceding observations may have conveyed.

To it is an old, but it is becoming more and more difficult, that in our profession we are but as the ministers of nature; and, indeed, the surgeon, still more than the physician, achieves nothing by his own immediate power, but does all his services by observing and managing the properties of the living.
the body; where the living principle is so strong and active in every part, that, by that energy alone it regenerates any lost substance, or re-unites, in a more immediate way, the more simple wounds." J. Bell's Discourses on the Nature and Cure of Wounds.

Of aneurism.

Wounded arteries cannot always be secured. Very often, as we have above stated, a large vessel is divided or punctured at a considerable distance from the surface of the wound, or in situations where the artery cannot be commanded: the blood is by consequence immediately and profusely poured out, spreads among the contiguous parts, and produces an aneurismal tumour. This is the false or diffused aneurism of authors, and the manner in which it is formed is sufficiently obvious.

The progress of this aneurism varies according to the situation and size of the artery that has been wounded. In the course of a few hours, the blood has been known to diffuse itself through the whole extent of a limb; at other times a very small tumour has been noticed, growing to great length of the same size for some weeks. As the increase of the tumour in false aneurism is generally occasioned by a diffusion of blood among the surrounding parts; it does not, like the true aneurism immediately to be noticed, become more prominent as it enlarges. In the first stages of the disease, a pulsation is almost always perceived in the tumour. This gradually lessens, and often at length becomes imperceptible. After some time, more or less according to the depth and magnitude of the wounded vessel, the skin becomes of a livid appearance, the member becomes stiff, painful, and the contiguous joint immovable, the integuments at length give way, and if the artery is large a fatal hemorrhage ensues.

When an artery has been accidentally punctured by the transfusing of a vein, an accident which sometimes happens sometimes between blood-lotting at the arm, the extravasated blood either diffuses itself into the surrounding cellular substance, or, when the vein and artery are more immediately in contact, the portion between the vessels is preserved; the vein, by the consequent impetus of blood comes to be dilated, and what has been denominated varicose aneurism occurred.

This kind of tumour may be recognized by the tremulous kind of motion which attends it, accompanied by a peculiar hissing noise, and by the tumour entirely disappearing for a time upon pressure.

When from accident or disease the coats of an artery lose in any particular point their ordinary power of resistance to the blood's impetus, and the diameter of the artery becomes in consequence dilated, the true or encysted aneurism is formed. It was, indeed, to this dilatation of arteries, without the rupture of their coats, and extravasation of blood, that the term aneurism was originally and is more properly applied.

In this manner it may be situated near the surface, the outer skin at first is of a natural appearance, the tumour is compressible, and a pulsation may almost always be observed in it. As the swelling increases, the skin becomes paler than ordinary, parts of the tumour are often firmer than others, and the pulsation cannot be discovered at all points upon pressure. Pain now comes on, the skin becomes discoloured as in false aneurism, an oozing of bloody matter is perceptible around the wounds, and if the seat of the disease has been a large artery, in one of the cavities of the body where compression cannot be applied, death is the inevitable consequence. Sometimes the fatal termination is occasioned by the gradual destruction of surrounding parts. Even bones have become carious in consequence of their proximity to a large aneurism.

Besides these three species of aneurismal tumours, the false, the varicose, and the encysted, Mr. J. Bell describes another disease, which he calls aneurism from anastomosis. This, our author observes, is constituted not by the dilatation of any branch of an artery, but by a mutual enlargement of the smaller arteries and veins; it proceeds from a trivial size to a large and formidable tumour; it is characterised by perpetual throbbing, which at length becomes a constant and distinct pulsation. It beats strongly when the circulation is unusually accelerated; in spring and summer, its pulsatory motions become fuller and more acute; it goes on to form sacs among the cellular parts, like the true aneurismal tumours. These enlarge, become at length livid, and burst from time to time; and then, as in other aneurisms, the tumour pours out its blood, and, according to its extent, reduces the patient.

Diagnostic marks. The existence of an aneurismal tumour is not always to be pronounced with decision, for although pulsation might be regarded as a true diagnostic character of the disease, it is not absolutely so; for other tumours may be situated so near a large artery, as to be regularly affected by its pulsations. When there is any doubt of the nature of the swelling, pressure should be made on it; and if it disappears or lesseis, and immediately recovers its size upon the pressure being taken off, it may be considered as an aneurism. In these cases, however, even of an aneurism, the reduction cannot always be effected.

Causes. The simple statement of the mode in which the two first species of aneurism above noticed are occasioned, is a sufficient account of the causes producing them. The true or encysted aneurism appears for the most part to depend upon a diseased disposition; often, indeed, it is brought on by violence or accident, but even then the predisposition is generally to be supposed. Women are less obnoxious to aneurism than men, especially the large aneurism of the thigh; and this Mr. J. Bell ascribes to their exemption from the hard labour of the other sex. To this conclusion, however, it has been objected, that even where the labour of females is greater than that of the men, and where even their occupations are such as to occasion those exertions which principally endanger the artery, the immunity is still the same.

When aneurism is produced gradually and without violence, this disposed pre-disposition is more evident. In this case, likewise, the prospect of cure from operation will be more faintly marked than when the tumour has succeeded to external injury; for this reason a diffused and varicose aneurism promises to be remedied by operation, with more safety than the true or encysted aneurism.

Aneurism, likewise, are more or less dangerous according to the origin of the disease. When they are formed in large blood-vessels near the heart, they are not the subject of operation; and it had generally been conceived that even in the extremities, when they were seated high up, in the axilla, or near to the neck, this would be inadmissible on account of the complete stoppage to the circulation, which was imagined a necessary consequence of obliterating the great artery of the thigh or arm. By an anatomical and practical investigation of this subject, it has, however, been demonstrated that the insculating vessels are in either instance sufficient to supply the limb; and that when failure attends the operation for aneurism, it is to be ascribed to other sources. In this substitution of the collateral branches for the arterial trunk, consists, indeed, the cure of aneurism, when it is effected without operation.

Treatment. The cure of every species of aneurism has been attempted by continual pressure on the tumour. In the false, or diffused aneurism, however, no advantage can be derived from this treatment. In the true varicose aneurism, moderate pressure may be attended with benefit; and even the true aneurism, when the artery is so situated that pressure can be made, has been cured according to the accounts of authors by this mode. Indeed, from the nature of this kind do not seem to promise any benefit, the operation ought to be speedily performed.

When first the operation for aneurism was practised, it was invariably the rule to secure if possible the large artery leading to the tumour by the tourniquet; then to cut into the sac, lay the cavity of the tumour freely and fairly open, clear it of the clotted blood, secure the artery by ligature, and treat the wound according to circumstances. In some cases it is necessary still to pursue this plan, as in a large and spreading aneurism of the groin; but where the artery leading to the tumour can be divided without sacrificing it, even before it reaches the cavity of the sac, it has been proved that this mode of operating is the most expedient. Mr. John Hunter first proposed it, by directing, in popliteal aneurism, that the great vessel from which it was resected should be laid bare on the front part of the thigh, that the artery should be obliterated by ligature at this part, and that the tumour, now deprived of its nourishment, should be left to be disintegrated by the sores. This plan is now generally adopted. The surgeon dissects down upon the artery, in the part which is judged most convenient for the operation, ties the vessel at two places at half an inch or more distant from each other, cuts it across in the middle between the ligatures, and thus destroys its communication with the tumour; the blood is gradually solicited by the insculating vessels, which become at length fully to supply the place of the trunk.

In performing this operation, the surgeon is to dissect the artery very clean; it should be carefully tied by itself, without including the adjacent giving nerve; a firm waxed ligature, without any intervening substance, is to

Surgery.
be passed round it by means of a blunt needle, or crooked probe, and the wound treated in the common manner.

In the aneurism by anastomosis, Mr. Bell observes that the only radical cure is complete extirpation; we are not to cut into it, or in any way attempt the interruption of any particular vessels leading into it, but the whole group of vessels by which the tumour is supplied must be entirely extirpated.

Of fractures.

Fractures are not in all instances easy of detection. Pain, swelling, distortion, loss of power in the injured member, shortening of the limb, and a peculiar crepitation sound upon the part being handled, are described as the signs denoting a broken bone; these, however, are all, excepting the last, which cannot in every case be perceived, in a greater or inferior degree, common to bruises, sprains, dislocations, and injuries independent of fracture.

When a bone is simply divided, without any protrusion of its broken ends, lacerations of considerable blood-vessels, or any other circumstance to render the accident complicated, the practice of the surgeon is obvious and simple: by a gentle and firm pressure, we have seen, adhesion is insured by merely bringing their divided edges together; in like manner, though much more tardily, junction will be effected between the divided extremities of a fractured bone, by replacing and preserving them in even and steady contact. The healing of wounds is not accelerated, but on the contrary retarded, by the several contrivances and interferences of the older surgeons: so by the cruel practice of tight compressing, bandaging, and the use of machinery, in fracture, not only unnecessary pain is occasioned to the patient, but the process of cure, instead of being facilitated and hastened, is considerably impeded. Nature, in either case, will not be interfered with.

The time which bones take in uniting is proportioned to the age and health of the individual. In persons of middle age and fifteen years and upwards, simple fractures of the arm will for the most part be fully and firmly united in a little more than a month from the accident. Fractures of the shoulder and thigh-bone are, under the same circumstances, about six weeks or two months in healing; while the smaller bones, as the clavicle, the ribs, the ischia, and the bones of the hand, seldom occupy in their cure more than three weeks.

In simple fractures, provided the parts have not been unduly irritated, either by much motion after the accident, or by tight straining bandages, the symptoms of inflammation will subside in a few days. Sometimes, especially when the surgeon has been called late, it is necessary to subdue the local irritation by solution of lead, the application of linement, and other means used in common inflammation, and these it is often necessary to continue for several days. Now and then it will be found expedient to bleed from the arm. These requisitions must be determined by the good sense and judgment of the surgeon. It is impossible to lay down abstract rules for conduct. To bled, however, merely because a bone is broken, is a practice equally unmeaning and erroneous with that before alluded to, with regard to wounds in soft parts.

Before speaking of individual fractures, we shall present the reader with the following instructions to distinguish between those that are due to fracture, especially applied to a broken leg, will be found applicable with proper exceptions to fractures in general.

"In setting a broken limb," says our author, "there is no extension required but much of care and attention; suppose you were not a surgeon. Lay the patient in bed, and lay the limb upon a pillow; if you design to use splints, have two long troughs, or pieces of pasteboard, (in figure 60 is represented the usual splint employed) in a fractured leg bent into a hollow form, lined, or rather cushioned, with two or three piles of flannel, with tapes or rubands, four or five in number, attached to the outside of the splints, by which bones are to be held. After all is gently tied together with bow-knots, to be slackened or tightened according to the swelling of the limb. The pasteboard ought to be soaked and softened a little, that it may take a shape suitable to that of the limb."

A long splint of this kind being laid flat upon the bed by the side of the fractured leg, desire one of your assistants to apply his hands broad round the upper part of the limb, and grasp it gently and steadily; take the foot and ankle in the same manner in your own hand, slip your left hand under the broken part of the limb, and then sliding it gently along, lay it upon the pillow or its splints. The pillow should be like a mat-trass, flat and firm.

Begin then to lay the limb smooth; let your assistant again grasp it, by spreading his hands upon the thigh or below the knee, with the design of extending along with you, not by lifting the leg from the pillow; but rather by keeping it down, andstyled by your pressure, while you with both hands lift the foot and leg: press them gently, but very firmly; raise them a little from the pillow, and draw them gently and steadily towards yourself. You have thus extended and smoothed the broken leg, in a manner which you almost suppose agreeable rather than painful to the patient, press it down steadily and gently; keep it flat and pressed until it gets a seat and bed in the pillow. If splints are applied, the limb is to be pressed against the lower splint; the upper splint is then to be laid above it, and by grasping the soft and moistened splints, you must model them as little. When the whole has taken a form, take several tapes one after another; and after having tied them in a general way, go over them again one by one, and tie them a little closer, so as to keep the limb agreeably firm."

This author, in another place, remarks (when speaking of fracture in general), "when the limb by accident has been disordered or shortened, you are to venture, without fear of hurting the callus, to extend it anew, and lay it straight again."

"It may be proper to observe, that while much inflammation is present, we are to defer the application of splints, even in the gentle manner above advised, till such inflammation has in a considerable degree subsided."
SURGERY.

see the directions given above. When the bones of the tarsus, side, and toes, are fractured, it will be necessary to apply a splint to the fractured part, and in general a large one beside over the sole of the foot.

Fractures of the upper extremities. Fractures of the scapula are by no means common: they are ascertained by the touch, by the great palpitating clear part, and by an incapacity of moving the arm. It is with difficulty that the parts are retained after replacement: a long roller is to be used, with which the shoulder is to be supported, and the arms to be kept suspended, in order to relax the muscles.

A fracture of the humerus is generally easy of detection. When it has been reduced, two splints are to be employed, and a flannel or linen roller is to be applied gently over them. The arm is to be supported in a sling. In a few days, or a week, from the accident, it may be examined, to ascertain whether the broken ends have been properly adjusted. In fracture of the clavicle, one or both bones are broken, the joint of the elbow is to be gently bent. Two splints of pasteboard are to be used, one large and long, upon which the arm is to be laid, the other small and slender, which is to be secured by slight tapes, ribbons, rollers, or the twelve-tailed bandage. (See fig. 63.) The arm, during the cure, is to be supported in a sling, with the palm of the hand towards the head.

When the olecranon is fractured, the arm must be preserved in an extended state, by a long splint reaching from one way above the elbow-joint, down to the point of the fingers. The arm should be hung by, and connected to, the side. In little more than a week from the accident, the dressings are to be removed, and a slight motion given to the joints, in order to prevent ankylosis.

When the carpal bones are fractured, there is usually considerable inflammation, which must, as much as possible, be abated by local applications: splints are to be employed as in fractures of the fore-arm, and the arm is to be supported in a sling.

In fractures of the metacarpus, a firm splint should be placed over the palm of the hand, which should be made to reach from the points of the fingers to the elbow. When a finger is broken, a splint of pasteboard, moistened and moulded into the form, is to be used; and a large roller may be applied all over the hand, in order to prevent the motion of the fractured finger.

Of fractures of the clavicle, ribs, sternum, and spine. A fractured clavicle may sometimes be perceived by feeling along the course of the bone. The motions of the shoulder-girdle are likewise necessarily impeded. In reducing this fracture, the arm is to be raised, so as to bring the ends of the bones towards each other; and it is to be preserved in this position till union is accomplished.

When a rib is fractured, which may generally be ascertained by feeling with the fingers, if one portion rises over another it should be reduced by moderate pressure, and the bandage may be applied all round the chest, which should be continued for some weeks. If a portion of the rib is forced inwards, some surgeons direct that an opening be made over the depressed part, which is to be elevated by the finger or forceps. When the sternum is fractured, a similar treatment is said to be required. In this last case it is necessary sometimes to trepan.

When the vertebrae are broken, the accident is for the most part fatal, and by the fractured pieces pressing upon the spinal marrow, a palsy is occasioned in the parts below the injury. The surgeon, however, is to attempt the displacement of the vertebra, as when part is depressed, an incision has been advised, in order to raise the depressed portion.

Of compound fractures.

These fractures are called compound in which the external teguments are wounded, from the same accident by which the bone has been broken. These are necessarily of much more difficult management than cases of simple fracture. Some surgeons indeed have indiscriminately recommended amputation of the limb in every case of compound fracture; while others have cautioned the propriety of preserving the limb, even for the worst accidents of this kind. This question, like many others, has been agitated too much in the abstract. The propriety of immediate amputation, or a prior attempt to preserve a limb, will depend entirely on the extent of the injury, but on the age, habits, and constitution of the patient, as well as the circumstances which he shall be under during the cure. In the army of every practice, amputation is often necessary, where in private it would be premature and cruel.

When we are to attempt the cure of a compound fracture, the first object is to remove such pieces of bone as are intermingled in the form of splinters, as well as other extraneous bodies. If there is merely a protrusion of the bone through the wound, without any separated pieces, we are to attempt an immediate reduction, as in simple fracture. If this cannot be effected even by pretty strong extension, an endeavour must be made to force the bone by pressure. If, on account of the narrowness of the wound, it is impossible to reduce the fracture, the wound must be dressed in the form of a stuffed bandage. It is sometimes necessary to saw off part of the projecting bone, in order to effect the reduction. When this has been accomplished, the wound is to be closed as much as possible, and compressing lint placed over it, and the limb secured by an eighteen-tailed bandage. In order to encourage adhesion, and prevent suppuration of the wound as much as may be, the limb without inordinate pressure should be supported as firmly as possible. When suppuration has come on, the limb is to be carefully dressed every morning. Indeed the chief business of the surgeon will be to preserve the wound clean and clear by regular washing and sponging, by laying clean lint upon it, and by the occasional use of spiritual applications. It is scarcely necessary to add, that the patient's health must be supported with much care. While causes of irritation are avoided, a due excitement must be kept up. (See the section on wounds.)

Of Luxations.

Dislocations, like fractures, are sometimes difficult immediately to discover. An inca- pability of moving the limb, pain, tension, a lengthening, shortening, or other deformity, and often considerable inflammation, are the general symptoms attending a dislocated or luxated bone.

Endeavours to reduce luxations ought to be made, as speedily as possible; as they grow older, they grow more difficult of treatment. Indeed, after a bone has been a considerable time dislocated from its place, it often forms a new and artificial joint for itself among the contiguous muscles, and the subject of the accident is by consequence rendered irrecoverably lame. When, however, dislocation accompanies fracture, it is sometimes necessary to cure the latter before the reduction of the former is attempted. This is the case when the fracture is contiguos to the joint.

When much local inflammation accompanies luxation, it is to be carefully subdued by the common anti-inflammatory applications: and, according to circumstances, it will be sometimes requisite to bleed at the arm. When the luxation has been reduced, the parts must be retained in their situation, by placing the limb in a relaxed position, and by applying appropriate bandages.

Luxation of the superior extremities. Of the arm as humeri. The shoulder-joint may be luxated by the head being forced downwards and backwards. The more usual kind of dislocation, however, is by the head being forced downwards and forwards. An upward luxation cannot happen without a fracture of the upper arm bones.

The signs of a dislocated shoulder are inability to raise the arm, the head of the humerus being felt out of its proper place, while a vacancy is observed under the acromion.

This luxation is often extremely easy of reduction. The surgeon should be provided with assistants to extend the arm, by means, if necessary, of a belt, or any substitute for this placed round the arm, with long straps attached to it, by which to extend the limb; another assistant is to draw back the shoulder-blade, while the operator, standing on the outside of the arm, directs the extension according to the situation of the bone, and thus reduces it. When several assistants are not at hand, an arm-dislocation may be reduced by placing it on the knee, and thus acting as with a lever. The arm, especially if the patient has been subject to the accident, may be supported in a sling some time after the reduction.

Luxation at the elbow is not common; it is attended with a shortening of the fore-arm, a projection behind above the elbow; while in the bend of the elbow the extremity of the humerus may be felt.

It is to be reduced by gradually extending the fore-arm rather in an oblique direction, and gently increasing the curvature of the elbow, and by endeavours to disengage the ends of the bones. After the reduction, the muscles should be relaxed by preserving the elbow for some time rather in a bent position.

When the fore-arm is dislocated at the wrist, the rotatory motion of the hand is prevented. After the bones are replaced, a tight flannel roller should be bound round the wrist, and the arm supported in a sling.

When the bones of the wrist are luxated, which by no means is a rare accident, much pain and inflammation follows, and the
motion of the joint is destroyed. The arm is to be supported, and but very gently extended, and the bones pushed into their proper position, which is to be preserved by bandages or splints. The metacarpal bones when dislocated are to be managed in a similar manner. When the thumb or fingers are dislocated, the phalanx is to be held by an assistant, while the surgeon elevates the dislocated end, and replaces it.

Dislocations of the inferior extremities.

Dislocations of the thigh-bone are not very common. This bone is however susceptible of displacement in four different directions: upwards and obliquely backwards, downwards and a little forward, directly forward upon the pubes, and backwards over the ischiatic notch.

In the first the limb is shortened, and the knee turned inwards. When the neck of the thigh-bone is fractured (an accident which has been confounded with dislocation), the knee and foot are on the contrary directed outwards; this may also in case of dislocation be more difficult than when the neck of the bone is fractured.

This dislocation is to be reduced by extension downwards and forwards. The patient is to be laid on his back, and a double sheet may be placed under his thigh, which being attached to some fixed points, will serve to raise and support the limb during the proper extension.

In a dislocation downwards and forwards, the thighs are reversed; the head of the thigh-bone may here be distinctly felt in the perineum. The extension in this case must have an upward and outward direction; its reduction is easier than in the preceding case. In returning the ball of the bone into the socket, the surgeon must be careful to act cautiously; too precipitate a reduction is apt to push it again out of its place, and produce an upward dislocation.

When the dislocation is forward upon the pubes, we are directed by some surgeons to lay the patient on his side, and support the thigh by means of a pulley fixed to some point above the joint, and operated thus assisted draw the bone inwards. In the fourth kind of hip-dislocation (over the ischiatic notch) the length of the limb is not interfered with; but the accident may be ascertained by the disappearance of the trochanters. Here the reduction must be attempted, by giving the bone an upward direction, while the knee is pressed inwards. The limb should not be used for some days after the reduction.

The patella can only be dislocated upwards and downwards by a rupture of its ligament or tendons; in this case the bone will be drawn up, and assume the appearance of fracture. It may however be luxated to one or the other side. For reduction, the limb must be extended; and in lateral luxation the edge of the bone at the greatest distance from the joint may be depressed, by which the opposite edge is elevated, and may be returned into its place. The patella is seldom luxated at the knee-joint; when the accident happens, it is easily detected. In reducing such a dislocation, the limb should be gently extended, and the bones replaced by the hand. Inflammation of the joint, with much solicitude, to be guarded against.

Dislocations of the ankle-joint are very rare. Indeed they are scarcely possible without a fracture of the end of the tibia. In reduction an extension of the foot, even with the leg, should be the object; then the bones are reduced. Luxations of the tarsal bones are to be treated in a similar manner. When the metatarsal bones and toes are dislocated, the reduction is to be effected as in the metacarpus and fingers.

Luxation of the spine, coccyx, ribs, and clavicle.

In consequence of the firm ligamentous connection of the vertebral bones, dislocation seldom happens without fracture. When it does, it is almost invariably fatal. When the coccyx is displaced, it may be generally felt protruding. It is to be reduced by pressure with the fingers. This bone is sometimes forced inwards and causes much pain, tenesmus, and sometimes a suppression of urine. In this case the finger is to be introduced into the anus, and the pressure made upwards. Dislocations of the ribs are exceedingly rare. It may be expected that the reduction is to be bent the body backwards, in order to press out the ribs.

When the clavicle is dislocated the end projects forwards under the skin, near its common place of junction with the breast-bone. The reduction is to be made by pushing the protruded bone in with the fingers, while an assistant pulls back the arms and shoulders. The arm is afterwards properly supported in a sling.

Luxation of the bones of the head and face.

When the cranial bones are separated, the head must be supported by a bandage. If one of the nasal bones is luxated inwards, it is to be elevated and reduced by inserting a tube into the nostril covered with lint. If the lower jaw is outward, the bone is to be pressed in by the fingers, and a double headed roller applied round the face. To reduce luxations of the lower jaw, which are not very uncommon, the thumbs pressed against the operator, the patient is to be kept in, and by the appearance of the tongue, the distance should be as far as possible between the jaws, and then the fingers acting upon the outside of the angle of the jaw, attempts should be made to bring forward till it moves a little. It is then to be pressed forcibly down.

Of amputation.

Thus, as it is now performed, scarcely any operation in surgery is more simple and secure. In preserving the extremities, so that they can be fairly brought over the stump, and properly to tie, or otherwise secure the bleeding vessels, constitute the points of practice in amputation; and, as we have previously shown, rank among the most important improvements in modern surgical practice.

The following are the general directions for performing amputation: The tourniquet is first to be placed on the most convenient part of the limb for securing the vessels. The tourniquet: a circular incision is then to be made with the amputating knife (fig. 71) or common scalpel, which is to pass all round the limb, and go through the skin and cellular substance; there are next divided away from the muscles to such a distance as will allow the divided edges of the integuments to come into contact over the stump. The skin thus separated is to be drawn up from the muscles, or turned back upon them, and kept by an assistant till the operator has made an incision at the edge of the reflected skin, beginning from beneath, and cutting in a circular direction down to the bone. The muscles are then to be separated from the bone, as the skin before was from the muscles, to such a distance, as to enable them afterwards completely to cover the end of the bone. The whole mass of flesh is then to be kept up from the bone by retractors (fig. 72 and 73); the peritoneum is to be divided all round in the place where the saw is to be applied, but not at all taken up from the bone: the saw (fig. 74) is now to be used, and the bone divided with long firm strokes, taking especial care that during this part of the operation the assistant holds the limb with steadiness. If there have been any splinters of bone left, they should be immediately taken away with pincers (fig. 75). The tendon is then cut, the principal arteries drawn up, and the nerve divided free from the nerver. Some warm wine, or other cordial, is to be given to the patient. The wound is to be cleared of blood, the muscles pressed, the joint to be fairly laid together over the stump; adhesions are to be broken, the requisite bandaging applied, the patient taken to bed, and the wound treated in the common manner (see section on wounds). Unless any untoward circumstance arises, a complete cure will be thus made in the course of a few weeks.

After this general statement of the mode in which amputation is to be performed, we might now be expected, as in our accounts of fracture and luxation, to go over the separate parts which at different times come to be operated upon. Such minuteness, however, would be inconsistent with our plan and limits, and we shall merely observe, that in all cases of amputation the above rules apply; that the surgeon must be determined by his own judgment respecting the particular point at which a limb should be amputated; that it must be accurately performed, and that what is indeed is almost too obvious to require notice, that in general as much as possible of the limb should be preserved.

Of joints, are to be operated upon in the way of amputation, further directions are necessary. Amputation at the larger joints ought indeed, in every instance, if possible, to be avoided; for a wound in a joint is, as we have already seen, invariably hazardous. When, however, in consequence of abscesses in these parts, compound fractures at the union of bones, caries, or other diseases, it becomes necessary to amputate at the joints, it will be necessary, after first securing the artery, to make a circular incision, as in common cases of amputation; then on each side of the limb another cut is to be made in a longitudinal direction, from the joint to the incision, and passing through the skin and muscles, which are to be now divided, and the limb removed. If during the operation any branches of arteries have been divided, these are to be taken up or secured, the wound to be closed, the muscles and skin brought neatly and fairly together. The
SUTURE.

473.

Union is to be effected by adhesive plaster and by proper bandages.

Wounds or injuries of the head.

Among many erroneous and unfounded opinions, this is by no means the most uncommon; that wounds of the head are among the most dangerous in proportion to the degree and extent in which the skull is fractured. "It is the injury of the brain alone which is dangerous; and very often are so close, the connection and sympathy of all the external and internal parts, that the brain is hurt by the very slightest injury of the scalp or bone, while the skull may be extensively injured, and the accident be comparatively trivial. Actions of the brain from blows or wounds of the head are immediate or secondary; the last are those which do not directly follow the injury from which they proceed, but make their slow insidious progress in the form of a disease. They are insidious, because they frequently arise to an alarming extent in consequence of a hurt which was at first deemed slight, and scarcely deserving of notice. They are slow; for after receiving such an injury, shall perhaps continue in seemingly perfect health, or with only a few signs of moment, shall at length fall a victim to the disorder, which has all this time lain as it were in embryo. One soldier, for example, shall have his temple grazed with a ball, shall hardly know that he is hurt, or be sensible for some time that he is indisposed; shall walk about for six weeks apparently in perfect health, and then all at once shall drop and fall low, become sick and weak; shall fall into a sort of a most dreadful struggling delirium, and then expire: and it shall be found, that the pia mater is separated from the skull, the skull itself black, and the brain matter mingled and oppressed with pus. While, on the other hand, another soldier in the same battle shall be so wounded with a sabre, that the scalp, skull and all, shall be cut clean away with a wound even of the brain itself, and yet the patient accounts, or which a soldier, wounded with a musket-ball, which is left sticking in the skull, with much depression, and many fractures of the bone, shall come to the hospital walking about on crutches, and in the instant restoration of the bone, and all the incisions and pickings of the bone which such a case requires; and shall eat and drink heartily, sleep soundly, and suffer not one bad symptom during the cure.

Most commonly, however, even in these secondary affections of the brain, a certain degree of sickness, faintness, and stupor, immediately follows the stroke, the blow, or the fall, upon the head. This from the state the man revives very slowly; at length seems to have regained his health, but after the lapse of some weeks perhaps, the faintness, sickness, and giddiness, recur; then come on fever, delirium, weight or pain in the head, and even a sign denoting a low inflammation of the brain; this state at length comes to be succeeded by paralysis, insensibility, and death.

This disorder is a plain case of a diseased dura mater, and an abscess of the brain, almost sufficiently evidenced by the progress of the symptoms, but rendered doubtful when on the surface of the skull arises a small, soft, puffy, regularly circumscribed tumour, not of the ephipetal kind, for that denotes a mere affection of the scalp, nor a soft and fluctuating tumour, for this may proceed from blood poured out from one of the cranial arteries.

"The trepan is in this case almost a hopeless operation, and yet it is to be tried." The intention of operating under these circumstances is, to discharge that matter which collected either between the dura mater and skull, or between the meninges and the actual substance of the brain, gives rise to all the distressing and alarming symptoms. When this is the case, it will be found necessary, not merely to trepan the skull, but to pierce the membrane. Such an operation will usually for a time lessen the patient's sufferings; but often he is again oppressed, and sinks and dies; or if he lives, great lungs sooner or later shoot up through the openings, and as by blood or matter, or at last oppressed, and dies commonly in convulsions.

The danger in this last case seems to depend upon the exposure of the brain by the operation; the surgeon then will be careful not to multiply openings for the discharge of a matter, for oppression and inflammation of the brain is just proportioned to the delay in opening the head: and on the other hand the danger after the operation is just proportioned to the number of holes.

The immediate injuries of the brain, as opposed to the secondary affections above described, are divided by surgical writers into those of compression and concussion.

A man, for example, receives a violent blow upon his skull, which by its force shall press in part of the bony defence of the brain directly upon the substance of this organ: he immediately falls down in a state of stupefaction; his pulse and breathing are oppressed; but no signs follow result from compression.

Concussion is a kind of injury more obscure in its theory, but not less fatal in its consequences. It is an internal derangement of the brain, or of the nervous system, which disconnection cannot trace, and which appears to be a shock to the whole, rather than an injury to any particular part of the organization.

In the former case, that of compression, relief may be expected from operation, but there is neither motive nor use in operating for concussion. In some instances of the former, blood-letting is imperiously called for; in the latter, to bleed is inevitably to increase the disease.

It is therefore absolutely necessary to decide early and clearly upon the precise nature of the injury. This decision, however, is not in every case easy even to the surgeon who may have had frequent opportunities of comparative observation. Most of the symptoms which attend compression likewise accompany concussions; and the existence of depressed bone, which must form, at least in part, a case of compression, is not always to be detected by external examination.

In cases of an equivocal or undecided nature, where it is imagined that compression may exist, although it is not perceptible, it has been advised by a modern surgeon to trepan in many different parts of the skull, in order to ascertain and remove the cause producing the symptoms. "It often happens," says Mr. Benjamin Bell, "that no external mark is to be made with to lead to the seat of the injury; even after the whole head is shaved, and examined with the most minute attention, the skull will in various instances be found perfectly sound, without any appearance either of tumour or discoloration. A patient in such circumstances we suppose to be in great hazard, from the brain being compressed in one part or another; unless this compression is removed by an operation, he must, in all probability, die. In what manner then is a practitioner to conduct himself? The situation is distressing; but still, in my opinion, there should be no hesitation as to the line of conduct a surgeon ought to pursue, which should be quite the reverse of what is almost universally adopted." This author, in another place, adds, "it will be proper to perform the first perforation in the most interior part of the cranium, in which it can with any propriety be made; and to proceed to perforate every accessible part of the skull, till the cause of the compression is discovered." Ben. Bell's System of Surgery.

In cautioning against such practice as is here condemned, we were particular, to give the judgment of the reader, under the sanction of high authority. It is observed by the celebrated Potz, "that symptoms of oppression are no good reason for cutting the integuments." And Mr. J. Bell, in his comment upon the above observations, thus addresses his readers: "I must in a few words entreat you to consider whether this practice would lead you. A boy is struck by another boy with a stone, lies for months against the nose, contumacy, and with every bad symptom; his surgeons are all the while advising the operation, his friends are pleading for a respite, when the boy begins gradually to recover, and the head is perfectly restored." Consider, our author goes on to say, "if in any given case, the patient lying oppressed, and having no mark of injury outwardly upon the head, you should advise the trepan; while a man who had studied more the common sense of surgery than the authorities of school-books, should prevent this unmeaning operation; and if in the mean time the patient should be entirely relieved, what would become of the young surgeon, if you should be allowed to perform the operation, and were to find nothing wrong, what consolation would that be?"

Indeed while there is but one motive for applying the trepan, viz. to relieve the brain from compression, whether that is from inflammation, or depression, or disease, a principal care of the surgeon ought to be, not to perforate the cranium upon mere suspicion of something lying somewhere, but on the contrary, to be ever wary of doing too much, rather than of effecting too little, in the way of operation.
We cannot better conclude this subject, than by again extracting the rules of practice from an author, whom, from a sense of the rectitude and value of his doctrines and precepts, we have often taken so much pleasure in following. Mr. J. Bell says, 'if there be an injury in the scalp, a burst of the skull, an internal separation of the dura mater, or any injury which endangers inflammation of the brain; and if along with that kind of danger there are actually symptoms which mark inflammation of the brain; we try to prevent or moderate the inflammation by bleedings. If there is a concussion, and the patient lies oppressed, vomiting, with difficult breathing and a slow pulse, (and this, it may be observed, is the most frequent, direct, or immediate injury from a blow or fall on the head,) we give opium, wine, and all forms of stimulants. If there are along with this oppression external marks of injury after an accident, such as might cause extravasation of blood, or depression of the skull, in such case our duty is first to open the scalp, so as to examine the skull, and next to trepan, if it is to be done; and then, in hopes of relieving the brain. If there is blood, it is to be known only by guess, by having opened the scalp at the place of the blow, in the expectation of finding a fracture of the skull, and distempering the skull, in hopes of finding blood lying upon the surface of the brain. But still, if after opening the skull the patient lie comatose and oppressed, in being plain he must die if not relieved. Also from the tension of the dura mater we suspect there is blood within that membrane; we must venture to open it also, in hopes of relieving the brain. If matter lying upon the surface is the cause of compression, it will be known by the previous symptoms, by quickness of the pulse, headache, flushed face, turgescent eyes, corded feeling in the head, and all the other signs marking an inflammation of the brain. And if after all these symptoms, shivering, languor, faintings, signs of vomiting, and delirium come on, we are sure of the case. If there is found a fissure of the skull, that fissure is not itself the cause of danger, but it is the mark of that degree of injury which may have produced it. It also marks the place of the violence, and points out where we should apply the trepan. A fissure is not of itself a motive for trepanning the skull; but if with the fissure the patient lies oppressed, then the operation is the mark of danger, perhaps from extravasated blood, and the fracture or fissure of the skull marks the point on which we should apply our trepan.

When the bones are directly pressed down by the blow, our way of proceeding is very plain; if the bones are moveable, we raise them gently up; if they seem totally disengaged, we pick them away; if the bones are locked in with one another, and pressed under the sound skull, we cut one angle with the trepan, and that enables us to raise the depressed bone. In all this operation we should be gentle, and rather reserved; for when blood has covered the whole skull, from the sagittal division to the parietal bone, it has all been evacuated by one single opening, and the patient saved. When there has been pus generated in great quantity, and much of the dura mater detached, one single perforation has been sufficient. When pieces of skull have been apparently so detached from their membranes, that they have seemed irretrievably lost, they have notwithstanding lived and healed, especially in young patients; and often when the depression has seemed far from being proceeded from, it is inexpedient to raise it, or has been so difficult to raise that he has forsaken it, the patient has lived notwithstanding the great oppression, and been restored to perfect health.

Operation. The operation of trepanning will necessarily vary, according to the circumstances of the case; the following are given as the general rules of practice: After the head is shaved, an incision is first to be made through the integuments, in such a form as to enable the surgeon, when the operation is over, to bring the edges of the wound as nearly as possible together; when the part has been fixed upon for the application of the instrument, so much of the skull is to be denuded of its pericranium by a raspatory, (fig. 13) as will allow the trephine (fig. 14) to be inserted. If a trephine be used, the operator, of sufficient depth to fix the central pin of the trephine, that the saw may be prevented from slipping; when the saw works steadily and securely, the central pin of the trephine is removed; the saw is then, from time to time, to be taken out of the groove, and cleaned by the brush (fig. 15). During the progress of the operation, the depth of the groove ought to be examined; if one part be deeper than another, the pressure of the saw is to be made principally on the opposite side. The operator must often examine whether the piece is loose; when it is perceived so, it must be snapped away by the forceps (fig. 16) or lever (fig. 17), for the sawing should by no means be continued until it is quite detached. Let the membranes of the brain are injured. When, after the piece of bone is extracted, the inner edges of the perforation appear ragged, they are to be carefully smoothed by the lenticular (fig. 18). The depressed portion of the bone is now to be raised with the lever; if there are any parts of bone which are likely to remain, they are to be pieced away, extravasated blood let out; and, as above-mentioned, if blood or matter is contained under the dura mater, this membrane itself is to be punctured. From the extent of the perforation, it is absolutely necessary to make more than one perforation; in these cases they ought to be made to run into each other, in order to prevent the necessity of dividing intermediate spaces. After the objects of the operation are accomplished, a pledge of lint, either dry or with some simple ointment, is to be laid on the wound in the dura mater (provided that membrane may have been punctured): the edges of the scalp are then to be brought nearly as may be together, and another piece of lint laid along the outer wound; some fine linen is to be placed over the whole, and the parts secured by proper bandaging, or by a common night-cap.

At every dressing the purulent matter is to be carefully absorbed by a sponge: the wound to be treated upon the same principles as wounds in general; and should fungous arise out of its edges, we are, according to their nature and extent, to attempt their removal by cautery, by excision, or ligature.

Of inflammation, its characters and varieties. Inflammation may be divided into ordinary, constitutional, and specific; the first dependent for its production upon those susceptibilities which in a greater or inferior degree are common to every individual, the second arising from peculiar tendency to disorder in some constitutions, the last always arising from the application of a particular exciting cause. For example, To that kind of vascular irritation which constitutes the inflamed state, and which is the subject of inquiry in another place (see Membrane, etc. Sect. Plegmatic), all are obvious, provided the exciting cause acts with sufficient power: but those inflammations that are called scrophulous, which are immediately excited by the same powers which are produced of communis, will not in all individuals follow upon the application of such powers; such then furnish examples of constitutional inflammations. As an instance of the third or specific inflammation, we may adduce the venereal disease, either in its first introduction into the system, or in several of its secondary stages.

As all these disorders have something in common, while at the same time each is distinguished by its separate character, so the rules of treatment in relation to them are both general and particular. Thus the observations which apply to the management of a common abscess (the result of inflammation), apply likewise, to a certain extent, to one resulting from the venereal virus, although the requisitions of this last are further regulated by the peculiarity of its exciting agent. We shall first treat of common, secondly of constitutional, thirdly of specific, inflammations. For the symptoms, progress, termination, and medical treatment of inflammation, consult Medicine. It is the simple surgery of this disorder alone that remains to be noticed. The local applications suited to the region, or, as it is technically expressed, resolution of an inflamed surface, when the inflammation is of the active or ethereal kind, are the different preparations of lead dissolved in vinegar, mild expressed oils, or simple oil. The first of these is often most conveniently employed in the shape of castor, made by mixing the dissolved lead, Goulard's extract for example, with crumbs of bread. This application ought to be cautiously renewed, and kept on the part cool. Lead is sometimes applied in combination with simple ointment; this, however, is not in general eligible, as the action of the lead is in some degree blunted by uniting it with oily or unctuous substances.

Local blood-letting by leeches, or by cupping and scarifying, is sometimes necessary, in order to reduce the inflamed state; and all heating, or otherwise irritating applications to the part, are to be assiduously guarded against. In passive, asthenic, or indolent affections of the inflammatory kind, it is sometimes necessary, even while the inflammation continues in its first stage, to treat the complaint with local well-assorted stimuli. In these cases we avoid cold applications, leeches, saturnine preparations, &c. and order warm and large poultices, made with mustard and oil, frequently renewed, fomenta.
ions, the inflation of white poppy, or of chamois-leather flowers, and sometimes even volatile emulsions.

When the suppurrative stage of active inflammation has commenced, the repellant applications are likewise immediately to be employed. Action is now not to be checked, but encouraged; warm fomentations are to be applied; poultices made with bread and milk, with a small quantity of lard or simple ointment, are to be resorted to; those are to be laid upon the part soft and warm, and renewed very frequently, and to be renewed. Sometimes when the suppurrative process seems too tardy and indolent, it may be necessary to add to the poultices some of the heating or stimulating gums, such as galbanum, which may be made to unite with the poultice, by dissolving it in the white of an egg.

The completion of the suppurrative process, or the full formation of abscess, is known by the cessation of throbbing, and other symptoms of suppuration, and by the pointing of the tumour. The tumour now becomes more distinct, from a whitish or yellowish appearance. Sometimes when the tumour is not deep seated, the fluctuation of matter is evident.

The methods of opening abscesses are by caustic, by incision, or by seton: the first, although in some cases, as in the case of the tumour, is present by no means in common use; it is more painful and insidious than the mode by incision. When caustic is employed, a piece of sticking-plaster is to be laid upon the tumour, to be laid upon the tumour, and then to the action of the caustic is to be introduced, and retained by plaster and bandage, until it has made an opening through the integuments of the tumour, which, generally, will not be some hours after its application. When an eschar is formed, some emollient ointment is to be employed to soften and separate it.

When the knife is employed, all that is necessary to attend to is, to avoid any considerable blood vessels, to make the opening large enough to give free outlet to the matter, and as the most depending part of the swelling.

When a seton is used, such an instrument as represented in fig. 1, may be threaded with a thread of sufficient length to reach the tumour, and passed out at the under; and the matter of the abscess thus allowed gradually to discharge itself. Dry lint, changed once or twice a day, is the only dressing necessary in a common abscess.

When an inflamed part, instead of thus passing on into suppuration, becomes gangrenous, the external applications are required to be of a stimulating nature; such as solutions of sal-ammoniac, &c., in general, however, the dressing of gangrene is to be trusted to internal invigorating powers, and keeping the part clear and clean. When mortified parts lie deep, and are not thrown off by the living energy of the surrounding surface, it is often necessary to make incisions into the skin for the purpose of removing them.

Of ulcer. When the ischar or mortified part has been separated, the sore remains in the form of a simple sore ulcer, which is one of the most common objects of surgical practice, the treatment of which is entirely resolvable into the means of assisting nature in her endeavours to procure proper and healthy granulations of fresh flesh, in preventing morbid luxuriance, and disposing to an even and clear cicatrization. Various methods have been had recourse to, in order to accomplish these objects, such as turpentine, warm stimulating ointments, in conjunction with the use of the excitement of which, and as the best application of the kind, we may notice the common basilicon ointment of the shops, with the red-precipitate powder. But the management of obstinate ulcers has recently been abundantly facilitated by the employment of simple adhesive plaster, which is cut into strips, and laid carefully, firmly, and neatly, over the whole ulcerated surface; these, where it can be used, to be assisted by bandage. This practice was first generally introduced by Mr. Brynton, and has, with justice, been ranked among the highest improvements in modern surgery. At every dressing of an ulcer thus treated, the sore is first to be cleaned by sponge and warm water; if, notwithstanding the uniform pressure of the plasters, fungous excrescences arise, they may be touched, when dressed, with some kind of escharotic; the eschar which has been then to be brought up as near together as the loss of substance will admit of; and the strips of adhesive plaster separately passed over the sore, till it is entirely covered. Over this dressing common castor-oil may then be laid, and the bandages then applied. When the ulcer is attended with much inflammation and swelling, the management of it for a time is to be solely entrusted to the applications of these. One of the most efficacious materials of which these may be constituted, and one of the best applications to obstinate ulcers of the leg, which are often attended with crysipilateral inflammation, is the grounds of stale beer.

This far of ordinary inflammation and its consequences: we now proceed to treat of this state as connected with, or modified by, a peculiarity of constitutional disposition. Inflammation is peculiar in their nature, and confined to certain parts of the system. Thus, inflammatory disorders of a scrophulous kind invariably affect secretory surfaces and cancerous inflammations, which are always in glandular parts. Suppose, for example, the breast of a female to be subjected to the causes of inflammation, the operation of such causes, if applied at a certain time of life, or under circumstances of cancerous predisposition, will end in the production of true cancer; the nature of the inflammation from the first being peculiar: while under circumstances of freedom from the cancerous tendency, an equal degree of irritation in the breast, without having any peculiarity in its nature and progress, or without demanding a specific mode of treatment. Further, even in an individual predisposed to cancer, inflammation of a part which is not glandular, will, by consequence, not be cancerous. What, therefore, we have denominated constitutional inflammations; are inflammations of certain parts, and thus branch out into distinct diseases. We have distinguished the principal inflammations from a scrophulous diathesis, although every secretory surface is obvious to the affection; these are white-swelling of the knee joint, and lumbar, poas abscess.

**White-swelling.** This disorder is most frequent in the knee joint, and indeed the name is usually made to denote a disease of this part.

**Symptoms.** Pain in the joint, especially on motion, or, when it is in a bent position, swelling, which generally augments, with an enlargement and varicose appearance of the cuticular veins; while the joint swells, the parts below become either diminished or affected with a scleromatous enlargement, parts of the abscesses at different points; gradual decline of the patient's health, hectic fever. Sometimes the pain is more confined, and it is often then more acute; at other times the pain and swelling are: from the first diffused through the whole extent of the joint.

**Causes.** White-swelling is a scrophulous inflammation. In those cases in which the enlargement of the joint commences with the pain, the pain itself being more distended, the primary affection seems to be an inflamed state of the capsular ligament; in other cases the disease is perhaps originally seated in the bones. Mr. B. Bell has described these different species by the names of rheumatic and scrophulous; but the fact is, that they both depend upon the scrophulous diathesis; and it has been well observed by an able writer, "that between acute rheumatism and white-swelling there is no sort of analogy, neither as to their causes, their symptoms, their terminations, their proper method of cure, nor any thing else." Dr. Herdman on White-Swelling.

**Treatment.** Both in the medical and surgical treatment of all scrophulous inflammations, it must be recollected that they partake more of the atherine than the opposite character. Thus in white-swelling, however violent the inflammation, or urgent the pain, blood-letting, general or local, is seldom or never advisable. Blisters, warm fomentations, and bathing, volatile liniment, the counter irritation of icerous issues, mercurial purgation, are the only remedies which yield any good air. When suppuration has taken place, "soft and easy dressings," warm poultices, small doses of calomel with opium. Cinta? Amputation of the limb, which is often performed to save the patient from the protracted necessity of riding, is not indiscriminately advisable, on account of the patient being, in some instances, too feeble and diseased to admit of the operation.

**Of lumbar or poas abscess.**

**Symptoms.** Pain in the loins, which does not, as in lumbar, affect the muscles of the loins generally, but passes rather upwards in the direction of the spine, and downwards in an oblique direction, towards the inner part of the thigh. After the existence of this pain, for a longer or shorter period, marks of suppuration come on, and a tumour gradually appears in the groin. This is to be distinguished from hernia by a recollection of the preceding symptoms, and by the fluctuating and fluctuating feel of the swelling.

**Causes and seat.** This disease appears to be an inflammatory affection of the vertebral ligaments, occasioned by an acute diathesis, of temperature, blows, or any violence done to the part, and other causes of inflammation: it terminates in suppuration, which runs along the sheath of the poas muscle, and thus appears in the groin.
Treatment. This, to be effectual, ought to commence with the commencement of the disease. When the ulcer has formed to any extent, the malady is highly dangerous. Plisters to the loins, volatile embrocations; very small doses of calomel, with opium or barytous. When a tumour has formed in the thigh, which continues to increase, it is to be opened. During the subsequent discharge, the patient's strength is to be carefully supported, by nourishing diet, wine, opium, brand, and pure air.

Cancer. Cancers, previously to their appearing in the form of ulcers, are termed occult. An occult cancer is a scirrhouss swelling of a gland, attended with lancinating pains, which state of parts often exists for some time before ulceration or open cancer is produced; this last, however, sometimes appears without any previous scarcity. The symptoms of cancer will be best described by tracing the usual progress of a cancerous breast. A small knotty tumour is generally seen on some parts which attends a mamma; this continues nearly in the same state, perhaps, for some months; it at length increases, and a pain is felt to proceed from it towards the axilla; the integuments gradually become discoloured, and at length ulceration is formed.

Causes and peculiarities. There has been much dispute whether cancer be a disease of parts merely, or of the system: all, however, that ought to be understood respecting the general nature of cancer, is, that it is a sequelability, as we have above endeavoured to explain, exists in some habits, and especially at certain periods of life, to this malady, which in such habits may be induced by the same causes which occasion common inflammation. The usual time for the formation of cancerous mamma is when the menses disappear. Previous to this period, swellings of the breast assume more of the scirrhouss character.

Treatment. Cica is has been much extolled as a remedy for schirrous; faith in its virtues are, however, gradually declining. It may be combined with small doses of calomel. Mercurial ointment to the part, volatile embrocations; not too stimulating. Laxatives has been employed as a lotion in occult cancer with seeming benefit. If the disease advance, no cure can be expected but from operation, which should be had recourse to early, previously to the extension of the disease into the contiguous glands.

Operation. If the skin be sound, a longitudinal or transverse incision, according to the shape of the tumour, is to be made with the scalpel along its whole length, at a small distance from the nipple; this incision is to pass through the skin and cellular substance, and while the patient's arm is extended, the mamma is to be carefully dissected from the integuments and pectoral muscle; the glandular substance should be detached, although only a part be the seat of the disease. In closing the integuments after the completion of the operation, the twisted suture may be employed, assisted by strips of oxidized linen. A plan of simple admission is to be laid over the part, covered by soft linen or tow, and the dressings are to be retained by appropriate bandage.

When the operation is performed, after the existence of the disease for some time in an open state, it will often be necessary to cut away with a knife at the root of the operation, in order to remove the incision may, in this case, be made of an oval form; and if the axillary glands be found scirrhouss, the scapel should be carried on full into the arm-pit, and the imbricated body carefully dissected out. When the operation is over, the divided edges are to be brought up as nearly together as possible, and dressings and bandages applied, as in other similar wounds.

VENEREAL AFFECTION.

The venereal disease is an example of that species of inflammation which we have called specific. It appears in two forms. To the one is more generally applied the denomination of syphilis; the other is called gonorrhoea virulenta. These affections are imagined by some to originate from the same specific poison; by others, the cause productive of true syphilis, and that occasioning gonorrhoea, are supposed to be of a different kind. This last is perhaps the best founded opinion, viz. that the matter which, when inoculated in the urethra, produces a discharge from the urethra, called gonorrhoea, is not capable, under any circumstances, of producing true venereal chancre.

Symptoms of gonorrhoea. A peculiar itchiness and smarting sensation about the extremity of the urethra, attended with some reddening or tightness; this is succeeded by the appearance of mucus about the extremity of the penis, which soon increases in quantity; it is generally of a brown appearance, and is attended with some irritation and pain in the organ, and by discharging the urine, and with nocturnal erections. Sometimes the lymphatic glands of one or both groins become inflamed, enlarged, and this form bubo. The time at which the symptoms of gonorrhoea make their appearance is variable; sometimes the disorder will follow impure coition in the space of a few hours; at others it will be several days.

Treatment. In the first and inflammatory stages, demulcents largely drunk, such as decoction of linden, solution of gum arabic, tragacanth, & c. Mild purgatives, such as cascara, are useful. Opiate at night. Bathe the penis in warm milk and water. Situations and pungent lotions. If from the too precipitate or early use of astringent injections, or from other causes, the inflammation extends itself to the testicle, causing pain and swelling of this part (hermias seminie), the scrotum is to be supported by bandage. Leeches are to be applied should the inflammation be violent, and the testicles be to preserved constant moistened with a solution of sugar of lead, or some other astringent preparation. For the swollen glands, friction with mercurial or common ointment and camphor. Volatile embrocation. If the inflammation cannot be expelled, the stone or stone-like portion to be dissolved by bread and milk poultices. If every symptom of the disorder go off, with the exception of a white mucous discharge from the urethra, which continues notwithstanding the use of antiscirrhouss injections, give tincture of cantharides in grain doses, or the same in electua, which will be for the most part found more efficacious than the balsams generally employed for this purpose. Should still the discharge continue, and, from the unusual appearance in the stream of urine, a stricture in some part or parts be suspected, introduce some instrument into the urethra, and try to evacuate the stone.

Symptoms of syphilis. True syphilis is perhaps invariably introduced into the system through the medium of chance, unless in cases where it is transmitted from parents to children. Chancre is a small ulcerated sore, with a slightly raised or eroded. This, when it appears on the penis, is frequently followed by an inflammation and enlargement of one or both groins; these, if neglected, pass on to suppuration; ulcers on the tonsils, succeed, with eruptions of the skin, especially about the roots of the hair; at length come on pains in the bones, which are often highly excruciating, and although sometimes taken for, to be distinguished from, rheumatic swellings, by their being rather in the centre of the bones, and deep set, than in the joints, and superficial; by their not being accompanied with fever equivalent to the violence of the pain; by the absence of that general prostration of the system which attends rheumatism, and sometimes by a circumcised swelling extremely painful growing up from the bone. When any doubt exists respecting the nature of those ulcers in the parts named, limbs are suspected to be venereal, they may generally be decided such by their peculiar coppy appearance: they are likewise, in general, more circumscribed than other ulcers, and their edges have a peculiar callousy.

Treatment. Mercurials given in such a form, and in such quantity, that what is called an alternative kind of action shall be for some length of time maintained in the system, without occasioning salvation, is an effect from mercury, which appears always to defeat its own object. Chances on the penis may, if the application be made to them a very short time after their production, be totally destroy-ed by caustic, and the absorption of the vi-rus and consequent disease thus prevented. When the scrotum is first perceived, they are to be kept from enlarging by the vigorous application of mercurial ointment, which, if not inconvenient, is perhaps the best and surest mode of introducing this medicine into the tissue. For other preparations of mercury, see MATERIA MEDICA AND PHARMACY. With respect to the time of continuing mercury, it may perhaps be laid down as a general rule, not to continue the medicine until two or three weeks after the apparent discontinuance of the disorder. Secondary affections, from the venereal action not having in the first instance been entirely subdued, are extremely frequent, and are always formidable. Opium, saraparilla, and, recently, nitrous acid, have each been judged specific for venereal affection; but it is now pretty generally supposed that they merely act as auxiliaries to the disease.

There are some other affections that were not noticed in the article MEDICINE, which depend upon a specific poison, and which, though constituted by a species of cutaneous inflammation, are not, like the exanthemata,公认的 abscesses, accompanied by febrile irritation. The cutaneous eruptions, which require to be noticed here, are the annulus repens, the man, and psora.

Annuus repens, ring-norma. This is a...
Surgery.

Treatment. Metallc or vegetable astringents in solution, such as nut-galls or white vitriol. The white precipitate ointment is spoken of as a wonderfully efficacious, in the hands of the men, in this and the two following complaints; the head to be covered during the cure with an oil-skin cap.

Tinea, scald head. This eruption commonly breaks out over the roots of the hair; it appears in small ulcers, which at times spread over the whole head, and produce friable crusts.

The secretion of the contagious matter, upon which this disorder depends, is generally excited by poverty of diet, irritation, and other malnourishment of infants.

Treatment. Shave the head; wash the surface first with warm water and soap; white precipitate ointment; tar ointment; a solution of corrosive sublimate; generous diet, with cleanliness.

N. B. A milder disease than tinea often breaks out on the face and head of very young children: this (crusta lactis) is not infectious. It is to be treated by keeping the child clean, cool, and much in the air; and by sprinkling the eruption with calamine powder, if necessary, which is likewise the best application to those excoriations of the skin which are apt to break out about the gums of infants.

Pomata. "Small pustules with watery heads, appearing first on the wrists and between the fingers." "There are two kinds of itch, which appears between the fingers and the joints of the knees and elbows, and which is seldom seen in these places, but all over the other parts of the body. The latter is seldom thought to be the itch, as it does not easily infect even a bull-flow, and resists the usual means of cure by brimstone."

Darwin.

Treatment. Sulphur ointment; mercurial corrosive sublimate in a very weak solution; white precipitate ointment; sulphur taken internally.

Of indolent tumour.

Tumours which are not necessarily or in their origin attended by inflammation, are called indolent; these nodular enlargements of parts are principally seated in the cellular membrane: they are differently named, according to the nature of their contents. When the swelling is made up of a substance of the consistency of fat, it is denominated sebaceous or fatty; if of a firmer consistence, a sarcomatous tumour. When it is filled with a substance the consistence of honey, the enlargement has been called a medullary or medullary tumour. The mass arthromatous is applied to those swellings which consist of a substance of a harder kind. Sometimes the contents of tumours are formed of a coagulable fluid, when they are termed hydatid. Sometimes there are swellings in the bursae or sinuses of joints.

These tumours may be removed by making an opening with a lancet, if their contents be of a fluid nature, evacuating such fluid, and afterwards removing their se. If the contents of the tumour are solid, they are to be extirpated by making a longitudinal incision on the side of the tumour, and removing the tumour by the point of the finger, or any convenient instrument that is blunt.

Of nuxi mentalis, corns, warts, and polypi.

When those marks on infants which are fancifully attributed to impressions made on the mind of the mother during pregnancy, do not rise above the level of the skin, they are not of course the subjects of surgical operations. Sometimes, however, these appear in the form of sarcomatous tumours, firm, prominent, and fleshly: in these cases the swelling may be cut out. If any considerable arteries run into it, these are to be taken up, and the skin that remains, brought over and united by adhesive plaster. If the tumour be connected with the sound parts by a narrow neck, it will generally be advisable to destroy it by making a ligature round its neck.

Corns are formed by a thickening and hardening of the external skin from pressure. They are to be treated by first bathing the feet in warm water, and then paring off as much as possible, without giving pain. This operation is to be frequently repeated; some simple ointment may be laid over the corn, and all pressure avoided as much as possible.

Polypi are indolent tumours found in various parts of the body, as the nose, mouth, throat, vagina, uterus, and rectum. When, notwithstanding the use of astrangent solutions, such as of alum, vinegar, &c., they continue to grow, become painful and troublesome, they are to be extirpated by the knife or scissors, when the roots of the tumour can be commanded, otherwise by tearing them out, and cauterising the wound. This is much more painful, not so cleanly, or in such cases much less painful, while it is more secure, by ligature, of wire, of catgut, of silk, &c. The ligature is to be passed double over the tumour, and carried to the root by the fingers, split probes, fig. 4. or rings, fig. 5. The ends of the ligature are to be now introduced into a canula, fig. 6. which is to be pushed along the opposite side of the tumour, till its end reach the root of it, when the ligature is to be drawn with some tightness, and fastened to the canula, which is to remain in the passage; the ligature is to be daily tightened till the polypus drop off. When the polypus is in the throat, the ligature should be applied through one of the nostrils.

Diseases of the bones.

Bones, like the soft parts, are subject to inflammation, which often terminates in caries, or a kind of gangrene, forming the disease called spina ventosa, or ganaeus ossis. This seems to be a septicacious affection.

Symptoms of spina ventosa. Dull heavy pains in the part, or originating without any perceptible exciting cause; lameness and sensation of weight in the affected limb; after the continuance of these symptoms for some time, without any appearance externally to indicate disease; the intermitten eruptions, suddenly perhaps, will become pitiable and unsightly. This arises from the matter having issued in a way that has become curious. Unfortunately attend to the restoration and preservation of the constitutional excitement and health. Bark, steel, very small doses of calomel, good air, nourishing diet, chiefly of ant mal food.

The fibrillities and maladies ossium. The one disorder constituted by a disposition in the bones to be broken or injured from the most trifling exertion; the other, by a want of firmness and hardness in the bone, are occasioned by disordered action in the secretory or absorbent vessels of these organs. They are alone to be remedied by internal strengthening remedies, suited to the nature of the prevailing malady.

The vascular node, as to its immediate cause, is obscure; the external swelling, with which after a time it is characterized, appears to be occasioned by an extension of the periosteum. Sometimes the pain of these tumours is mitigated by dividing the periosteum.

Among the diseases of the bones is often classed an affection which is very common, especially in young children, viz. a loss of power in the lower extremities, consequent upon a displacement of some part of the bone of the bony column of the spine. This, in fact, appears to be a disease of the ligaments. The frequency of this complaint in children is so great as to prevent, the treatment, to be effectual, ought to commence early, and in its origin. Unless attended to with care, it is apt to be mistaken for a nervous or common infantile indisposition.

Symptoms. An unusual backwardness in walking, languor, listlessness, a tendency to hysterus, and lastly, a feeling of protrubence or curvature in some of the spine.

Treatment. A seton in the back near to the disordered promontory, small doses of calomel, as in other septicacious affections. Nourishing diet, cleanliness, air.

Of erosion and arteriotomy.

Blood-letting from the arm is an operation so simple and familiar as hardly to require notice. The ligature that is used for the purpose of stopping the venal circulation should consist of broad tape; this is to be firmly bound round the arm about an inch or two above the joint of the elbow; the intermediate space between this and the hand of the joint is in general the most convenient for introducing the lancet. The surgeon is to make choice of that vein which rolls least under the median basilic, although not always the most prominent, is usually chosen, both on account of its being less apt to slip from under the lancet, and because there is less danger of injuring any cutaneous nerves when the cephalies are opened. The artery being felt to pulsate below is not to be regarded as an objection; for transfixing the vein under any circumstance should be carefully guarded against; and unless the instrument be thus carried through the
Surgery.

The usual most parts of opening an issue are on the fore part of the humerus, the hollow above the inside of the knee, the neck of the tusk, the spine or between the ribs; in the two former places the pea or blister issue is commonly used, in the others the cord or seton.

A blister issue is made and kept up by the common blistering plaster being first applied, which is followed by the daily use of chantharies ointment. The pea issue is sometimes made by cautie, but more commonly, and much better, by puncturing the skin in up, and cutting it through, making a wound of sufficient size to receive the common issue pea; this is to be daily removed, a fresh pea put into the wound, and thus a purulent discharge will be excited and maintained.

The seton is to be made with the seton needle, (fig. 8.) threaded with cotton or silk, this is to be pushed into the skin, and carried out at some distance, passing the instrument fairly through; and, when the eyes, which is cord that may be employed is to be left hanging out from the orifices; the cord is to be daily drawn out and renewed.

Diseases of the eyes.

Inflammation of the eyes is of two species; the one called by systematics, ophtalmia membranarum, inflammation of the membranes of the eye; the other, ophtalmia tarsi, inflammation of the teardrop glandular and scrofulous affection. Membranous inflammation is to be subdued by satirical lotions, by bleeding with leeches on the temples; and if the disorder be violent, and the inflamed vessels very turgid, by cutting the vessels across upon the eye. Light, and all other sources of irritation, it is hardly necessary to observe, should be kept from the eye as much as possible.

Ophthalmia is very apt to be treated by rubbing over the lid, when the eye is closed, some of the active mercurial ointments, of which perhaps the most efficacious is the ung. hydragyri nitriti of the London Pharmacopoeia.

Munibromous inflammation, if violent or long continued, is apt to be followed by specks on the cornea; these may sometimes be removed by absorbent remedies, local or general, such as colostom thrown into the eye through a quill, or small quantities taken internally so as to produce a very gentle mercurial action in the system. Sometimes, when the speck on the cornea is very prominent, it may be removed by a small knife. When the membranous excrecence termed pterygium, spreads from the white of the eye over the cornea, a scarification should be made through it entirely round, and at a little distance from the circumference. After the hemorrhage has subsided, a satellite lotion is to be applied to the eye.

Inflammation now and then terminates in an abscess of the eye, which confines the humour to a small space, and thereby makes it impossible to abstract all the matter by incision. When this occurs, the matter must be evacuated by an incision into the cornea. Ucers of the eye may arise, from the same causes, constitutional or local, that occasion ulcers in other parts: the general principles of treatment must likewise be the same.

The serous humour of the eye sometimes accumulates inordinately, and constitutes a kind of dropical swelling of the organ; this disease is to be distinguished from abscesses by the manner in which it has been produced, by the patient remaining sensible to light, and by the pupil contracting. Dropsy of the eye may be remedied in its early stages by purgating the under edge of the cornea, or by piercing the sclerotic coat just behind the iris. After the operation, some tincture and astrigent lotions are to be used.

It is sometimes necessary to puncture the eye, in order to discharge blood that may have been extravasated from its vessels and remain unabsorbed.

When the eye has become cancerous, the whole of it is to be dissected out, free from the lids, if the operation is performed before these parts have become diseased.

Cataract. This is a disorder either of the crystalline lens or of its capsule, preventing the rays of light from falling upon the retina. Cataract usually commences by a diminution of vision, followed by the sensation of пар-1 and permanent opacity, and is at length succeeded by almost total blindness. This disorder is usually without, but is sometimes accompanied with pain. It is distinguishable from the gutta serena by the want of pain, which in the last disorder is not present. In phthisic serena the pupils do not contract in a strong light; in the cataract, the contraction of the pupil usually remains. Whether the capsule mere or the lens, the opacities of the lens, is affected, it is not easy to ascertain.

In the commencement of cataract, advantage has sometimes been experienced from small doses of colonel, hyoscyamus; cicutas and electricity have each been used with supposed benefit. When the disorder is confirmed, it is only to be removed by an operation, by shaving or extraction, by forcing the opaque lens down into the vitreous humour, or by excision or cautery operations.

Qf couching. 'The operator is either to be seated with his elbow resting upon the table, or, which is preferred by some, he ought to stand resting his arm upon the side of the bed, or table, or even fixed by the speculum, (fig. 19.) or in such a manner as to allow the whole of the cornea and a small portion of the sclerotic coat to protrude, a couching needle, (fig. 21.) is to be held in the right hand in the manner of a writing pen, if the left eye be the subject of the operation; the ring and little fingers are to be supported upon the cheek or the temple of the patient; the needle is to be entered in an horizontal direction through the sclerotic coat, a little below the axis of the eye, and about one-fourth of a line behind the edge of the cornea, so as to get entirely behind the iris, to prevent that substance from being wounded. The point of the needle is to be carried forward till it be discovered behind the pupil. The operator is now commonly directed to push the point into the lens, and depress it at once to the bottom of the eye, and the better to bring the lens either bursts through the capsule at an impasse it carries with it tearing, the parts with which it is connected. Instead of this, the needle ought first to be pushed into the
lens near its under edge, as Dr. Taylor advises, and then carried some way down into the vitreous humour, so as to clear the way for the lens. It is then to be drawn a little back, and carried to the outer portion of the capsule; and, by pressing upon it, the lens, if solid, is to be pushed down by one, or if fluid, by several movements, to the bottom of the vitreous humour. It should then be pushed downwards and outwards, as Mr. Bell directs, so as to leave it in the under and outer side of the eye; where, in case it should rise, the passage of the light would be little obstructed. The needle is then to be withdrawn, the specimen removed, and the eyelids closed; and a compress soaked in a saturation solution to be applied over them. It is not advisable, in general, to remove the dressings till about eight or ten days after the operation.

**Operation of extracting the lens.** “The operator takes the knife, (fig. 23.) and holds it in the same way as he does the needle for conjunctivitis; he then enters the point of it with the edge under the lower part of the cornea about the middle of one half a line from its connection with the sclerotic coat, and as high as at the centre of the pupil; he is then to pass it across the pupil to the inner angle in an horizontal direction, keeping the edge of the knife little forwards or from being cut; the point is then to be pushed through opposite to where it entered; the upper half of the cornea is next to be cut, and at the same distance from the sclerotic with the parts at which the point of the knife went in and came out from the eye. In cutting the upper half of the cornea, the pressure of the speculum upon the eye should be gradually lessened; for if the eye be too much compressed, the aqueous humour, with the cataract and part of the vitreous humour, are apt to be forced suddenly out immediately after the incision is made. The operator then takes a flat probe, and raises the flap made in the cornea, while he passes the same instrument, or another probe, (fig. 24.) rough at the extremity, cautiously through the pupil, to scratch an opening in the capsule of the lens. This being done, the cataract is to be pressed till the pupil is closed, or the eyelids are to be shut, to allow the pupil to be dilated as much as possible; and while in this situation, if a gentle pressure be made upon the eyeball, at either the upper or under edge, or orbit, the cataract will pass through the pupil more readily than it would do when the eyelids are open. If the lens cannot be easily pushed through the opening of the cornea, no violent force should be used, for this would tend much to increase the inflammation. The opening should be enlarged so as to allow the lens to pass out more freely. When the cataract does not come out entirely, or when it is found to adhere to the contiguous parts, the end of a small flat probe or a scoop, (fig. 25.) is to be introduced, to remove any detached pieces or adhesions that may be present. The iris sometimes either projects too much into the anterior chamber, or is pushed against the opening of the cornea. When this happens, it is to be returned to its natural situation by means of the probe already mentioned. Sometimes the opacity is not in the body of the lens, but entirely in the capsule with it. The extraction of the lens alone would here answer no useful purpose. Some practitioners attempt to extract first the lens and then the capsule by forceps; others the lens and capsule entire.” The after treatment is to be the same as in connexion with the operation.

A difference of sentiment prevails respecting the superior eligibility of the one or the other of these operations. Among the surgeons of London, the extraction is principally advised.

**Of fistula lachrymalis.**

An obstruction of the lacrimal sac or duct constitutes this disease. It is divided into four stages: the first is constituted by a mere dilatation of the sac, and is characterised by a tumour between the inner corner of the eye and the nose, attended with a discharge of tears and mucus over the cheek, the integuments being entire, and as yet free from inflammation. In the second stage the swelling is larger, the skin inflamed, and out of the puncta lachrymalia may be now pressed a yellowish purulent fluid. The lacrimal duct, and being round the diseased duct; in the fourth, the passage from the sac into the nose is obliterated, its inside being ulcerated or fungous, and the bones being cavernous; it is only then to this last stage that the term fistula can with propriety be applied.

It has been attempted, by the introduction of a probe (fig. 27.) from one of the puncta lachrymalia into the nasal duct, to overcome the obstruction, and by some surgeons the intestiments: the injection of astringent fluids has likewise been proposed by means of a syringe, (fig. 28.) the pipe of which is also to enter one of the puncta; but these operations are scarcely practicable and all perhaps that, in the first period of the disorder, ought to be attempted, is frequent pressure with the finger on the tumour; when the disorder advances, and the tumour threatens to burst, an opening should be made into it with a small scalpel, beginning the incision a little above the line from the angle of the eye to the nose, and laying the sac fairly open; the contents of the tumour are then to be pressed out; and we are advised to direct for the nasal duct with a probe, and if it can be found, to introduce a piece of catgut bougie, or lead, bending it downwards so as to preserve it in the passage to the sides of the involved duct. The wound is to be dressed with wax and oil, and the dressings retained by sticking plaster. When the passage of the duct is secured, the substance that had been introduced is to be withdrawn, and the wound healed.

In the last, or properly fistulous, stage of the disorder, the attempts at cure are attempts to procure a new duct for the passage of the tears, the original one being obliterated. For this purpose the canula of the trocar (fig. 30.) is to be introduced to the under and back part of the lacrimal sac, and retained while the stilette is to be passed in it in an oblique direction downwards and inwards, till it reach the nasal cavity; the perforation of the bones will be perceived by the operation; and the passing of the instrument into the nostril, is usually followed immediately by the passage of some bloody mucus out of the nose; when this has thus penetrated the spongy bones, it is to be withdrawn from the canula, and a leaden probe or piece of catgut introduced. The canula is now to be removed; one end of the probe is to remain in the new-formed duct, and the other, as small as is practicable, to hang over the edge of the wound, which is now to be covered with lint and adhesive plaster. The probe is to be removed almost daily until the new duct is completely calous, when it is entirely to be removed, and the wound healed.

In cases of much constitutional affection, where the disorder treated in the above manner is likely to recur, it has been proposed to introduce a cane of gold, silver, or lead, into the artificial opening, and to heal the skin over it. The instruments used for this purpose are represented in figs. 31, 32, 33.

**Of diseases of the teeth.**

The causes of tooth-ach are obscure. Caries of the teeth seems to be sometimes a constitutional, at others an entirely local disease. For the preservation of the teeth, they ought to be kept constantly brushed, with a brush simply, or with some powder that is not of an ionic nature. For acids, although for a time they cleanse and whiten the teeth, eventually injure their texture; the salts constitute the objection of gold, silver, or lead, as commonly termed dentifrices powders. Tooth-ach when it proceeds from a disease of the tooth itself, only admits of temporary cure by the common applications of opium, camphor, and the warm essential oils. The empirical remedies for diseased teeth are perhaps generally composed of some strong concentrated mineral acid, by which the carious is for a time separated from the sound portion of the tooth.

**Extraction of the teeth.** Many are far too liberal in disposing of their teeth: if the first fit of the tooth-ach be endured, the disorder will frequently, for years, or for life, be suspended, and the tooth remain sound, which by a precipitate extraction would have been unnecessarily lost. In some, there is a tendency, from the fear of the operation, to the other extreme. When a tooth is extensively out, and the means to be extracted, for the sake of preserving those that are contiguous and the momentary pain of extraction is trifling in comparison of the multiplied and protracted fits of tooth-ach.

The instruments for extracting teeth operate in a lateral direction: it is indifferent on which side they are forced out, whether outwardly or inwardly, excepting in the instance of the denues supinator of the lower jaw, which ought invariably to be forced outwardly. Before the claw of the instrument is fixed on the tooth, the gum should be separated from it as deep down as possible; the fulcrum of the instrument is to be on the side opposite to that at which the tooth is to be extracted, and with a single turn, which should not be by jerk or violence, but made with a slow, regular movement, the tooth will come out of its socket.

From very violent affections of the teeth, and from other causes of inflammation, the membrane of the alveolar sac sometimes inflames, and becomes the seat of abscess. When the symptoms of this disease are violent pain in the cheek, and swelling extending upwards towards the nose, the ears, and the eyes; the swelling generally points in the
cheek, and sometimes a discharge of matter takes place from the nostrils or the roof of the mouth. This discharge is to be cured by making a free opening for the discharge of the matter, either by extracting one of the molars and perforating the antrum with a trocar (fig. 37), through the bottom of the socket, or by extracting a tooth, the perforation may be made with a tubular instrument through that part of the antrum which projects over the molars. Astrigent solutions may be thrown occasionally into the cavity, generally depend on the

Of rana. An obstruction in the duct of one of the salivary glands sometimes produces a tumour under the tongue, of such a size as to impede the motion of this organ, and at length to threaten suffocation. This tumour is to be laid fully open, and the mouth may afterwards be washed with some astrigent solution.

Enlarged tonsils and cheeks are not unfrequent occurrences. When these by their size interfere with respiration or swallowing, they are to be removed by ligature in the same manner as polypi. When the enlarged tonsil is of a conical shape, Cheseled's needle (fig. 43.), may be employed, which, when passed through the tonsil, is to be pushed through the base of the tumour; the tonsil now being taken hold of by a hook is to be pulled forward, divided, and tied, so as that each division shall surround each half of the swelling. This kind of ligature may be employed for an enlarged uvula or polypi.

Deafness, when consequent upon an incorrect position, hardening of the wax, is best removed by squirting the ear with warm water in which some soap has been dissolved. When deafness arises from mere dryness in the meatus, some drops of sweet oil should be put into the passage. The supplicative discharge from the ears in young children may generally be relieved by some slightly astrigent lotion, such as a weak solution of vitriolated zinc or sugar of lead. When contained upon loss of nervous power, either local or general, no relief can be expected from these topical applications. Electricity has been tried with apparent benefit in these cases.

Branchotomy. When the trachea is to be opened, we are directed to make a longitudinal incision, of about an inch and a half, through the skin and cellular substance, commencing at the under end of the thyroid cartilage; the muscles are then to be separated, the operator taking care to avoid the thyroid gland: when the trachea is laid bare and the bleeding vessels secured, a puncture is to be made with a common lancet between two of the rings of the trachea, of such size as to admit a canula. Dr. Monro directs that a double incision is to be made in the inner and outer sides withdrawn from time to time, and cleared of the obstructing mucous. He directs the instrument to be fixed by a strap round the neck. As soon as the purposes are accom-

plished for which an opening was made into the trachea, the canula is to be taken out, and the wound closed by adhesive plaster. The

Paracentesis of the throat. When the chest is opened in order to evacuate purulent matter, this cavity, an incision should be made with the scissors through the skin and cellular membrane, between the sixth and seventh ribs, from one to two inches long; and, in the direction of the ribs, the muscles are next to be divided, and the incision made as near as possible to the upper edge of the inferior ribs. The pleura now exposed is to be gently opened; if the lungs adhere to the ribs where the incision is made, the fluid will not immediately discharge itself from the opening: in this case, the adhesion may be separated by a blunt probe, or the incision may be carried a little on towards the sternum. When the fluid begins to flow out, a silver canula (fig. 43.) may be introduced into the wound, attached to the patient's body, and being provided with a cork to it, the operator is either to let out the whole of the matter at once, or to draw it off frequently according to the strength of the patient. The wound, after the evacuation of the fluid, is to be kept open for some time.

Paracentesis of the abdomen. Tapping is usually performed by puncturing the abdomen at the middle line between the spine of the ilium and the navel. Others direct the opening to be made in the linea alba. An equal pressure is required during this operation upon the belly; such pressure may either be done by the operator, or by the hands of assistants; the part at which the puncture is to be made being drawn a little over the edge of the bed, if the patient be found lying in a horizontal situation, the surgeon fixes the head of the instrument (a trocar) while the forefinger directs its point; he is then to push it forward till it ceases to meet with resistance. The perforator is now to be taken out, and the water allowed to discharge, while the pressure on the surrounding parts is continued and increased. After the whole of the water is drawn off, the wound may be covered with a pledge of simple lint. This may be laid some flannel dipped in spirits, and bandages are now to be applied round the body with firmness. The bandages should not be removed for one or two days succeeding the operation; after this time they may be taken off daily for a little while, and the abdomen rubbed with some stimulant embrocation.

Hernia. From malformation, pre-disposition, or accident, the contents of the abdomen may protrude beyond their boundaries, and thus constitute hernia, or rupture. The most usual place for descent is through the ring of the external oblique muscle, constituting the inguinal canal or scrotal hernia, and hernia congenita, from under the ligament of falcipus or poupourt, forming fununal hernia, and from the navel constituting umbilical hernia.

The causes of rupture we have said are either pre-disposition, accident, or malconformation. Where the constitutional tendency is observed, the tracking causes should with solicitude be avoided. These are violent muscular exertion, particularly of those muscles whose action is principally upon the contents of the abdomen, such are especially called into action in violent straining to procure stool, in fits of coughing, hurried respiration, laughter, &c.

It is hernial congeits alone that immediately follows upon malconformation, strictly speaking. It is occasioned by the protrusion of some portion of the bowels through the passage by which, just previous to birth, the testicles descend from the abdomen into the scrotum. This passage is commonly shortly closed after the descent, and thus the intestine prevented from entering the bag of the testicle. In the case of congenital hernia the opening is preserved.

Hernie, with the exception of the one just mentioned, are invested with peritoneum, and thus enclosed in a sac; and to whatever extent the protrusion may have taken place, the tumour still forms in a manner a part of the abdominal cavity. Rupture is an improper application for the disorder.

It may be conceived that parts thus protruded, even before the occurrence of the immediate inconvenience with which they are attended, are in no measure free from danger of serious and alarming consequences. We have been mentioning, for instance; a part, in many cases, of the bowels, which the intestines are constantly passing forward to the anus; and this swelling, so disproportionate to the passage through which it has been protruded, that it is only in some situations of the body, when the parts are not full and tense, that in any case, and with duly managed pressure, they can even for a time be made to resume their former and natural situation.

The reduction of hernia ought then, by all means, to be attempted as soon as it is perceived; and future descents prevented by constant and uniform pressure over the part where the displacement had taken place. For the different kinds of these used for this purpose, see figs. 42, 43, 44.

When, from neglect on the part of the patient, a hernia is incapable of reduction, and is at the same time free from pain or stricture, the operator should be observed in avoiding a repetition of the causes which produced the disease. The alvine discharges are to be regularly maintained, and all violent exertions guarded against; and, without care, an irreducible and increasing hernia often continues through life without any impediment in the functions, or any interruption in the communication between the protruded and contained portions of the abdominal contents.

The dangerous symptoms in hernia originate either from spasmatic stricture of the aperture through which the sac and its contents have passed, or from distention and inflammation of the parts protruded: in this last case, indeed, the symptoms may be attributed to stricture; for the opening, although of sufficient size to allow of the communication between the tumour and the abdominal cavity previous to their falling into disease; now that parts of this disease are preternaturally enlarged and inflamed, becomes too narrow for such communication; its unyielding edges form a stricture on the inflamed vessels, and thus increase the inflammation and its consequences. The disorder is now called strangulated hernia. The
SURGERY.

721

signs of approaching strangulation are the following: pain in the tumour, an unusual tenderness over the whole belly, increased by any exertion of the abdominal muscles, consti- tiveness, quickened pulse, nausea, vomiting, and increase and extension of the pain, greater tumescence in the abdomen, extreme anxiety, and other symptoms of peritonal inflammation.

These symptoms demand speedy remedies; vera to avoid the consequences and pain are already too violent to admit of attempts to reduce the rupture, they should be, if possible, subdued by fomentations over the tumour, and the whole of the abdomen, by the injection of plasters, by warm baths, and by topical and general blood-letting. The return of the bowels should as soon as possible be attempted, for inflammation may have been present for some time without so much as a trace of rupture having been reduced as to prevent reduction, if properly regulated. The patient should be placed on the side opposite the hernia, with his pelvis and lower limbs raised, in order to relax the muscles; the abdomen should be grasped, a fistula made with the fingers in a direction upwards, and a little inward towards the crural arch, if the hernia be of the thigh; upwards, and outwards towards the ring, if it be an inguinal hernia. When the symptomatic symptoms continue, the tumour is incapable of reduction, and every appearance proves a complete strangulation of the hernial sac; there is no safety for the patient, unless in the operation which we are now briefly to describe for the inguinal and femoral hernia, which are the principal and almost only cases of strangulated hernia for which the surgeon is called upon to operate.

Operations for inguinal or scrotal hernia. The patient should be laid with his body in an almost horizontal position; while the buttocks are somewhat elevated, the thigh are to be brought down, and secured by assistants; the parts are first to be shaved, an incision is then to be made with a scalpel through the skin and cellular texture, commencing about an inch above the tumour, and carrying it down some way, but not allowing the fingers, being thus exposed, a directory to be introduced between it and the sac, in a direction upwards and outwards. A blunt pointed bistoury is to be inserted in the groove of the directory, and the ring dilated by this instrument till the point of the finger can be introduced; while the surgeon makes the dilata- tion of the ring sufficient to reduce the hernia, he must be careful of not dilating too freely, lest the bowels be again forced down. The stricture being thus relieved, the protruding intestines are to be re- turned, the outer wound closed with stitches, and proper bandages applied. When the wound has cicatrized, a truss should be worn.

The operation for femoral hernia is performed much in the same manner. Here the structure is from the ligament of the thigh, which, after the sac has been opened, is to be divided to the requisite extent.

Hydrocele. Hydrocele, or dropsy of the scrotum, is either encysted or anascorous; either diffused through the cellular mem- brane, or contained within the tunica. The anascorous hydrocele is distinguished from the encysted by the general spreading of the tumour, by its comparatively rapid progress; and although it sometimes depends upon a local cause, by its being more usu- ally connected with general dropsy. Anas- corpuscular hydrocele is treated by incision, or punctures; but usually this is not the case, and the dropsical tendency be counteracted by general remedies, much advantage is not to be expected from either.

Hydrocele of the vaginal canal generally first comes on with a sense of fulness about the inferior part of the testicle, which gradually becomes more tense, and rises higher in the body of the testicle: the increase of the swelling sometimes occasions the penis almost to disappear. The tumour throughout is scarcely attended with any pain; it is usually, but not invariably, transparent; its transparencynce and fluctuating feel, indeed, have been a criterion to distinguish this from scrotal hernia; but such distinction is formed with more accuracy by the manner in which the disorder has commenced and proceeded, viz. from below, upwards; the converse is the case with hernia) and by no de- gree of pressure during the swelling to dis- appear.

The tunica vaginalis may be punctured, and the water drawn off as in other species of hydrocele. In the former only a temporary, not a radical cure. The radical treatment consists in not merely evacuating the water from, but causing an irritation be- tween the vaginal and abdominal coats of the testicle, to make them adhere, and thus obliterate the cavity. This is effected by in- cision, by caustic, or by injection; the last of which, recommended by Mr. Earle, is now, on account of its mildness and safety, very generally practised. The water is first drawn off by a trocar passed into the under and fore part of the tumour; the canula of which is still left in the orifice, the operator securing it with one hand, passes the tube of an elastic bag (filled with red wine somewhat diluted) directly through the canula; he then injects the contents of the bag into the cavity, leaves the tube of the instrument, which is provided with a stop-cock, in the canula, by which the injected fluid is regulated. This, after remaining about five or six minutes, is to be taken out, and the fluid suffered to dis- charge itself through the canula.

The wound in the testicle is now to be co- ored with a pledge of lint, and the testicle itself is to be supported in a suspensory band- age, and the patient confined to his bed for some days. After this method of treat- ment, hydrocele is apt to return, but the opera- tion can then be repeated.

The spermatic cord is subject to hydro- cele, both of the anascorous and encysted kind. The latter is sometimes confounded with hernia, but may be distinguished from it by the tumour commencing at some distance down the cord, though it is still above the testicle, which is not the case in the hydrocele of the tunica vaginalis. This swelling may likewise be distinguished from hernia by its not being altered in size from any posture or pressure. When the tumour becomes large, the palliative, or radical cure, as in the va- ginal hydrocele, must be resorted to.

Varicocele is an unusual dilatation of the veins of the testicles. When this affection is slight, the physician, by controlling the use of the spermat- ic cord, may desist from further practice; should it become great, the patient will be relieved by the operation as follows: a small incision is made in front of the testicle, and a small ligature of silk is thereby passed over the spermatic cord, and tied in the manner of a suture.
SURGERY.

left hand, while with his right he introduces it with its concave side turned towards the body; the left hand is now to draw the penis gently forward, and upon the instrument, which is thus gradually inserted into the bladder. If the sound drop immediately upon the stone, the surgeon will feel a tremulous motion. In this, however, he must be careful that he is not deceived. If the instrument is right, as at first introduction, hit upon the stone, it is to be moved in various directions, or the finger may be passed into the anus, or the body of the patient placed in different postures. Even if after these trials, the existence of stone does not appear obvious from sounding, the operation may in a day or two be repeated.

To dissolve stone in the bladder various expedients have been practiced, but with success. All that art has hit upon been able to accomplish, is in some measure to obviate the constitutional tendency towards its production, and nothing appears more effectually to operate in this manner than a long continued use of vegetable or mineral alkali, accompanied by a saline salt. (See Medica et Phar- macy). The pain of stone may sometimes be temporarily relieved by opiates and other antispasmodics, as well as by analgastic tonics.

Of the operation for extracting stone. (Lithotomy). Two methods only of performing this operation are in the present day spoken of: the one, the high; the other, the lateral operation; and, indeed, the former, which consists of making an incision into the bladder above the pubes, is almost entirely laid aside. It cannot be done without wounding the peritoneum, and, consequently, endangering inflammation of this membrane, the mischief from which have been already experienced on. See the section on wounds.

The lateral operation was first performed by Frere Jacques, a French priest. It was practiced and improved by Cheselden, and has recently undergone some alterations.

The patient, properly prepared by laxatives, enemas; &c. without being too much rounded, is directed to lie on his back, with the urine some hours previous to the operation. The periym and neighbouring parts are to be shaved.

A table, a little more than three feet in height, is to be covered with blankets, pillow, &c. upon which the patient is to be laid, and secured in the following manner: Two pieces of broad tape, about five feet long, are to be doubled, and a noose formed upon them, to be passed over the patient's wrists; the patient is then to lay hold of the middle of his foot upon the outside; one end of the tape is to be passed round the hand and foot, and the other round the ankle and hand, and the turns repeated in the reverse way; each hand and foot is then to be tied; the buttocks are to be brought an inch or two over the edge of the table, and by pillows to be raised higher than the shoulders. One pillow should be placed under the patient's head.

The surgeon is now to introduce a grooved staff (fig. 51) through the urethra into the bladder, with this he feels the stone; he then, with the staff, brings it into the right groin, so that its convex part may be felt in the perineum, on the left of the raphe. He then fixes it, and gives it to an assistant, who holding it with his right hand, is to press it gently, until, with his left hand, he raises and supports the scrotum. The operator, now, with great nicety (fig. 52), brings the thighs, makes an incision with a convex-edged scalpel through the skin and cellular texture, immediately below the symphysis pubis, which is just under the scrotum, and where the crus penis and bulb of the urethra meet; and on the left side of the raphe, and in a slanting direction, continues it downwards and outwards to the space between the anus and tuber of the ischium, terminating somewhat lower than the base of that process. As soon as the incisions are thus divided, two fingers of the left hand are to be introduced, with one keeping back the lips of the wound next the raphe, and with the other pressing down the rectum. The surgeon should be particularly careful not to cut the crus of the penis, which can be easily felt and separated with one of the fingers at their under part. The surgeon now makes a second incision about two inches deep, and as low down as possible, first, but rather nearer the raphe and anus. The transversalis penis will by this second incision be divided, and as much of thelevator ani and cellular texture as will make the prostate gland accessible to the finger.

The operator now has a view of the membranous portion of the urethra; he is to seek the groove of the staff with the fore finger of the left hand, the point of which is to be pressed up against the head of the urethra into the prostate gland. It is to be kept there, and turning the edge of the scalpel upwards, he cuts upon the groove of the staff, and divides freely the membranous part of the urethra, from the prostate gland to the bulb, till the staff can be perceived perfectly bare, and the point of the finger admitted.

The prostate and neck of the bladder are now to be divided, which may be done by a scalpel, but the gorget (51) is more usually employed. The membranous part of the urethra being divided, and the fore finger retained in its position, the point of the gorget, previously adapted to the groove, is to be placed, there, on the edge of the finger, which will serve to conduct it into the groove of the staff; to this particular attention is to be given. The operator now rises, takes the staff from the assistant, raises it to nearly a right angle, and presses the convex edge against the symphysis pubis; again satisfies himself that the back of the gorget is in the groove of the staff, and then pushes on the instrument till its point slips from the groove into the bladder; farther than this the gorget is not to be carried, lest the opposite side of the bladder be wounded. The entrance of the gorget into the bladder will be shown by the intermediate discharge of the urine from the wound; the staff is now to be withdrawn, and the finger pushed up along the gorget to search for the stone, that the manner of introducing the forceps may be known; at least that the finger serves to dilate the wound in the bladder. A pair of forceps (fig. 52) are now to be introduced with their blades shut close, and the gorget is then to be drawn slowly away in the same direction in which it entered. The handles of the forceps are now to be depressed till they are completely opened; one blade is to be directed towards the symphysis pubis, when the stone is touched, the blades of the forceps are to be opened and moved in various directions, so as to lay hold of the stone; if the operator find a difficulty in doing this, the forceps may be introduced into the rectum, and the back of the bladder which may lodge the stone, elevated. If the forceps happen to grasp the stone, in a direction inconvenient for its extraction, it should be permitted to fall back, and the operation repeated. The stone should be extracted slowly. When it has broken in the bladder, or is in detached pieces, the scoop (fig. 53) or finger may be introduced to remove the smaller fragments. Sometimes it is necessary to inject the wound with warm water, and raise the patient's body, in order to wash out some of the remaining concretions.

When any considerable artery bleeds, it is, if possible, to be taken up with a ligature; if this cannot be done, pressure is to be made on the wound with a firm roller.

When the operation is over, the pelvis of the patient should be placed lower than the body, in order to preserve the wound in a dependent position, to facilitate the discharge of urine. When the urine has subsided, the bandages are to be united, a piece of dry lint put between the lips of the wound, which is to be often renewed, and the thighs are to be brought together. The patient is then to be laid in a bed, with the pelvis low, a large dose of laudanum given; and when much pain is afterwards complained of in the abdomen, anodynes are to be given by the mouth and by enema, and fomentations, with bland warm water, to be applied to the parts. Sometimes after the operation of lithotomy, the wound will be healed in a month; at other times, even if the operation be successful, the patient will be confined for three or four months.

Incontinence of urine. This may arise from various causes; loss of power in the sphincter of the bladder, irritation about the neck of this organ, laceration of its coats, or pressure from the uterus in advanced stages of pregnancy, are those which may be conceived fully adequate to produce an incontinence or suppression of urine. When a suppression of urine arises from deficient power in the bladder to expel its contents, the catheter (figs. 73 and 79) is to be introduced as the same manner as the sound, in order to draw off the water; in cases likewise of suppression from the pressure of the gravid uterus, the catheter is often employed with much advantage.

When the urine is retained in consequence of irritation and inflammation in the neck of the bladder, the disorder is violent and alarming; it is characterized by the ordinary symptoms of inflammation, attended with an extreme pain and much swelling of the affected parts, so that the catheter cannot be introduced. Treatment: Topical and general; blood-letting, anodyne fomentation, opiates in large dose; injections into the rectum of warm water, warm bath.

When the urine is retained in consequence of irritation and inflammation in the neck of the bladder, the disorder is violent and alarming; it is characterized by the ordinary symptoms of inflammation, attended with an extreme pain and much swelling of the affected parts, so that the catheter cannot be introduced. Treatment: Topical and general; blood-letting, anodyne fomentation, opiates in large dose; injections into the rectum of warm water, warm bath.

The patient is now to be introduced into a warm bath, and by lotions and warm applications to the perineum, the parts about the wound will be brought to a healthy state. When the urine is retained in consequence of irritation and inflammation in the neck of the bladder, the disorder is violent and alarming; it is characterized by the ordinary symptoms of inflammation, attended with an extreme pain and much swelling of the affected parts, so that the catheter cannot be introduced. Treatment: Topical and general; blood-letting, anodyne fomentation, opiates in large dose; injections into the rectum of warm water, warm bath.
Surgery.

about an inch and a half above the pubes directly into the bladder, and withdrawing the stilete to permit the urine to flow through the canula; to this point a cork is to be fitted, so that the urinary discharge may afterwards not be continued, and by drops, but at intervals.

When the puncture is made from the perineum, the trocar must be introduced at a little distance from the raphe perinei, and passed into the bladder, a little to the upper and outer side of the prostate.

Fistula in perineo. A sinusous ulcer in the perineum may be produced by injury in the bladder or in neighboring parts, or may arise from inflammation of these parts, common, venereal, or carcinous. When the complaint is local, it is to be treated by incision in the manner of other fistulous ulcers, and dressed with emollient applications, or with poultices, according to the nature and degree of the inflammation and discharge.

Fistula in ano. This is a sinusous ulcer in or near the rectum. It is called disease of the integumentary or, independent of the gut, while it is at the same time communicates with the gut. When there is no actual communication of the ulcer with the rectum, it is called an incontinence of the tube, or any external opening, the ulcer communicates with the gut, it is termed occult ulcer.

Fistulous ulcers near the rectum, may be produced by any local causes of irritation, they frequently follow upon the inflammation produced by obstinate hemmoroidal affections. Piles, indeed, are perhaps the most common source of fistula in ano. These are to be remedied by laxatives of a bland and oily nature, by sitting over warm water as the best means of softening the parts; and if the pain and swelling are considerable, by the application of leeches upon the tumour: such applications are principally suited to what are termed blind piles. When the disorder is accompanied by a discharge of blood from the anus in an excessive degree, cold and astrigent are to take place of warm and emollient applications, such as solutions of sugar of lead, which application of cold water, while costiveness, even in the case of bleeding piles, is to be carefully guarded against, by laxatives: chaly beets internally will often be attended with much advantage. The fistula ferrea maritini of the London pharmacopoeia, has been given as a preventative of piles, with much apparent benefit. In the treatment of the complaint, it ought always to be examined, whether it acknowledges a local or a general cause, and whether the hemmoroidal disposition depends upon debility, which is often the case, and is then only to be combated by tonic agents.

When an abscess has formed in or about the rectum, and the tumour points externally, a free incision ought to be made into its most depending part, in order to discharge the matter as speedily as possible; the wound is then to be covered with soft linen, upon which is spread some simple ointment; and is to be bandaged. When the parts are much inflamed, a large emollient poultice laid over the dressing.

When the abscess has been permitted to open itself either externally or internally, and has formed a sinus ulcer, which is known by the nature of the discharge, the direction of the sinus or sinuses must be ascertained, by feeling with the finger in the anus; when the course of ascertainment, free incision is to be made along their whole length; the patient is to be placed so that his body shall lean upon a table or a chair; the surgeon is to introduce his finger, previously oiled, into the rectum. A crooked probe-bored history is then to be inserted into the fistula, and pushed against the finger in the rectum; the instrument is now brought downwards, the sphincter of the anus divided, and the sinus thus opened. When the fistula is occult, it is necessary to make an artificial opening, previous to the passing of the bistoury. After the sinus or sinuses have thus been laid open, plettages of lint or soft linen spread with a simple ointment, are to be gently introduted into the wound, and a compress of soft linen applied over the surface, and kept there by bandage. The dressings during the cure are to be often renewed, at least once in twenty-four hours. Abscess will sometimes form slowly in the rectum, and discharge its contents without any fistulous ulcers following. In these cases, after the discharge of the matter, much advantage is often found by the use, for some time, of astrigent and deducting injections, such as of lime-water: which the patient himself, by means of a syringe contrived for the purpose, may use with ease and safety inject.

SURVEYING OF LAND. Surveying, or the measurement of the surface of the earth, is by some supposed to have had its origin in Egypt, and that, more especially, on the banks of the Nile; the inundations of which are said to have obscured the landmarks which the stock-owners yearly made between their neighbours' properties and their own; and to avoid this annual inconvenience, it was found necessary to devise some plans of form and dimensions which they could employ after every inundation. Such was the opinion of Herodotus, Proclus, and others, who have continued to the present age, but it is not our intention to justify such opinion, and we are rather disposed to countenance a position laid down by a modern traveller (Mr. Brown) who has spent much time on the borders of the Nile. He tells us, in Upper Egypt the river is confined by high banks, which prevent any inundation of the adjacent country: and so it is, whose angles, except at the extremities of the Delta, where the water of the Nile is never more than a few feet below the surface of the land, and where, of course, the inundations take place; here, however, the country is, as may be expected, without inhabitants. But wherever the origin of this science may have been, the usefulness thereof is, now-days, well known and appreciated.

Geometry is the foundation of land-measuring; and we shall proceed to the most practical rules for finding the areas of such geometrical figures as occur in surveying.

Square. The area of this figure is found by squaring the length of either of its sides, or, by multiplying the base by its perpendicular; as in Pl. XVII. Fig. 1, AB is therefore the area. So also, AB x BC = the area.

Parallelogram, rectangle. The area hereof is found by multiplying the length by the breadth; as AB x AD = the area. See fig. 2.

Rhombus, or Rhomboids. Multiply the base by the perpendicular height; thus, in fig. 3, AB x ED = the area.

Also, when two sides and their included angle are given, the product of those sides multiplied by the natural sine of the angle = area; that is, AB x AC x sin B = area.

* * * The angles of a regular rhombus are each 60°; those of a rhomboids may be more or less.

Triangle. Multiply the base by a perpendicular derived from the opposite angle; half the product is the area; \[ \frac{ab \times s}{2} = \text{area.} \] (Fig. 4.)

Also, when all the sides are given, from half the sum of the three sides subtract each side severally; multiply the half sum and the three remainders continually together, and square-root of the last product will be the area; that is, \[ \sqrt{\frac{ab + c + d + e}{2} \times \frac{ab + c + d - e}{2} \times \frac{ab + d + e - c}{2} \times \frac{c + d + e - a}{2}} = \text{area.} \] (Fig. 5.)

Trapezium. Divide it into two parts by a diagonal line; demit perpendiculars from the other angles. Multiply the diagonal by the sum of the two perpendiculars; half the product = area; (fig. 6.)

Or, when it can be inscribed in a circle, and the sides are given; from half the sum of the sides subtract each side severally; multiply the four remainders continually together, and the square-root of the last product will be = area; (fig. 7.)

\[ \sqrt{\frac{a + b + c + d}{2} \times \frac{a + b + c - d}{2} \times \frac{a + c + d - b}{2} \times \frac{b + c + d - a}{2}} = \text{area.} \] (fig. 8.)

Regular Polygons. When a side and a perpendicular deduced from the centre are given, half the perimeter multiplied by the perpendicular = area; (fig. 9.)

\[ \frac{ab + ac + bc}{2} \times G = \text{area.} \] (fig. 10.)

When only a side is given, the square of the side multiplied by the tabular number or multiplier below = area.

That is, \( AB \times \text{tab. num.} = \text{area.} \)

Circle. The square of the diameter multiplied by 7854 = area; (fig. 10.) i.e. \( AB^2 \times 7854 = \)
To reduce the statute measure to either of the customary measures, the following rules will apply:—first, if the customary measure is smaller than the statute, as the Devonshire for instance, say, the square of 15 is the number of statute acres, so is the square of 16.5 to the number of customary acres; secondly, if the customary measure, as the Cheshire for instance, say, as the square of 24 is to an acre, or number of acres, so is the square of 14 to the number of acres customary.

Before a measurer begins his work in the field, he should consider what lines are necessary to be measured, and the lines to be obtained for the content; taking such as the least walking forward and backward.

Having carefully measured such lines as will reduce the field to some of the simplest figures, before-mentioned, with such of their measuring lines as may be necessary, he will be enabled to find the content of each part, by the rules laid down in the former part of this article.

We would observe, that a measurer may divide the same field different ways, and obtain the content thereof by each. For instance, the field ABCDE (fig. 15), may be divided into a trapezium ADBC, and a triangle ADE.

Or, it may be divided into four triangles, as in fig. 15.

It may also be divided into six triangles, AEs, DAs, CAs, and Bed, and two trapezoids DDe, and BAs; as in fig. 16.

The calculations for the quantity of land in the same field, by the four respective methods of taking the dimensions, will stand as follow:

Fig. 14.

Trapezium ADBC = \( \frac{2}{2} \) \( \frac{2}{2} \) = 420000

Triangle ADB = \( \frac{a}{2} \) \( \frac{a}{2} \) =

\( \frac{780 \times 231}{2} \) = 97800

\( \frac{9.3756}{11.24} \) 9.3756

5 acr. 2 rds. 11 perches, as before.

Fig. 15.

Trapezium ADBC = \( \frac{2}{2} \) \( \frac{2}{2} \) \( \frac{2}{2} \) = 694400

Triangle ADB = \( \frac{a}{2} \) \( \frac{a}{2} \) =

\( \frac{1020 \times 470}{2} \) = 47900

\( \frac{2.1118940}{5.66990} \) 2.1118940

5 acr. 2 rds. 11 perches, as before.

The calculations for the quantity of land in the same field, by the four respective methods of taking the dimensions, will stand as follow:

Fig. 16.

Triangle AEs = \( \frac{2}{2} \) \( \frac{2}{2} \) = 48600

Triangle EDAs = \( \frac{2}{2} \) \( \frac{2}{2} \) = 148500

Triangle CDAs = \( \frac{2}{2} \) \( \frac{2}{2} \) = 23000

Triangle Bed = \( \frac{2}{2} \) \( \frac{2}{2} \) = 19200

Trapezoid DDe = \( \frac{2}{2} \) \( \frac{2}{2} \) = 241000

Trapezoid ADe = \( \frac{2}{2} \) \( \frac{2}{2} \) = 574480

\( \frac{11.118890}{3.66990} \) 11.118890

5 acr. 2 rds. 11 perches, as before.

We have hereunto confined our consideration to such figures only, whose sides are straight lines of considerable length; but, as the general boundaries of many pieces of land consist of short indentations, it is necessary to avoid the tediousness of computing the contents of a multitude of small triangles and trapezoids; to find such equalizing lines as shall constitute a triangle, or other figure, of equal area with the sum of all such triangles and trapezoids combined.

Suppose, then, that an irregular boundary of a field is of the form of fig. 18, composed of two triangles and four trapezoids.

Draw the line AB, and at A erect a perpendicular—Lay a parallel line from A to the third point. Move the upper part of the rule to the line AB, and note where it cuts the perpendicular, as at 4. From this point 1, divide the line into four equal parts, and mark the perpendicular at 2—From 2 draw the line AB, and raise it to 3, and mark the perpendicular at 4—From this point lay the rule to the line AB, and raise it to 5, and mark the perpendicular at 6. From 6 draw the line AB, and the triangle A5B, be equal in area to the aggregate of the two triangles and four trapezoids.

Examples.

Suppose that, on some well graduated scale, the base of the triangle A5B, was found to be 185, and perpendicular, 8, 110; the base, 8, of the adjoining trapezoid 250, and sum of its perpendiculas 103; the base, 4, of the next trapezoid is 120, and its perpendiculars 180; the base 6, and the perpendiculars of that trapezoid 100; the base of the next trapezoid, and the perpendiculars thereof 94; the base of the latter triangle, 15, and its perpendicular, 99; and that the content of the whole is required.

Suppose also, the content of the triangle ABC, whose base, 4, by the same scale, is 180, and perpendicular AC, 258, is required.
SURVEYING.

First. The double of the

Triangle
Base \(= 185 \, \text{X} \, 110 \) = 20550
Trapezoid \( = 290 \, \text{X} \, 160 \) = 46000
Do. \( = 120 \, \text{X} \, 120 \) = 14400
Do. \( = 395 \, \text{X} \, 190 \) = 71550
Do. \( = 300 \, \text{X} \, 349 \) = 104700
Triangle \( = 630 \, \text{X} \, 289 \) = 182070
\[ 20550 + 46000 + 14400 + 71550 + 104700 + 182070 = 383070 \]
\[ 2 \times 383070 = 766140 \]
Content, 2 ac. 0 rds. 24 perches. 245760

Second. The double of the triangle

\[ \text{ABC} = \text{AB} \times \text{AC} = 1810 \, \text{X} \, 385 = 430730 \]
\[ 2 \times 430730 = 861460 \]

Content, 2 ac. 0 rds. 24 perches, as before.

From whence it appears, that the content of the new triangle is the same as the aggregate contents of all the original triangles and trapezoids, to within the decimal of a perch.

In working with a chain and its offsets staff, a measurer does well in making a rough sketch in his field-book, large enough to admit of his writing down the lengths of all the necessary lines, whether for planning, or for casting off the content without a plan.

Where there is a general base line, with several perpendiculars raised thereon, it may be best to continue the receding throughout that line, and, by subtraction, find the intermediate distances between one perpendicular and another.

Example. Suppose from the sketch and dimensions of fig. 19, a true plan and the content of the field were required.

Beginning at A, draw a line to the tree at the upper end, and thereon prick off the distances, as in the sketch.

At the proper points erect the perpendiculars, according to their respective lengths; and the true figure will be as fig. 19. The whole content may be found, by seeking the separate content of each triangle and trapezoid, from the dimensions given in fig. 19, thus:

The double content of the triangle \( \text{a} \, \text{b} \, \text{c} \)
\[ 330 \, \text{X} \, 100 \] = 33000
The double content of the triangle \( \text{d} \, \text{c} \, \text{e} \)
\[ 2 \, \text{X} \, 500 \] = 10000
\[ 5 \, \text{X} \, 600 \] = 30000
\[ 3 \times 10000 = 30000 \]

The double content of the triangle AB\( \text{cd} \)
\[ 4 \, \text{X} \, 289 \] = 1156

The double content of the triangle B\( \text{d} \)C
\[ 3 \times 300 = 900 \]

The content 6 ac. 2 rds. 21 perches. 21428

Hitherto we have supposed all the measurements to be taken within the fields; but a measurer may sometimes use fields so circumstances, by woody ground, meres of water, &c, as not to admit of the necessary internal lines being taken. Such pieces of land may, however, be measured, by taking surrounding lines, making one or more right angles with each other, and raising perpendiculars from those lines to the angular points of the fields; by which a true plan may be constructed, and from thence the content found, either by equalizing the sides by the parallel ruler, or by deducting the contents of the small parts with, from the general content of the trapezium or surrounding figure: see fig. 21.

Example. A plan of the piece of woody ground

\[ = \text{the aggregate of all the small trapezoids; which taken from 824613 (the content of the surrounding trapezium), leaves 566410, = 5 } \text{acres, } 80 \text{perches, the content, as before.} \]

Thus far we have applied ourselves to single fields only, but we will now proceed to the measuring of two or more, lying contiguous to each other.

Example. From the dimensions given in the sketch, fig. 28, the contents of the fields A and B are required.

Field A \( = 620 \times 290 \times 1000 \)

\[ 2 \times 620 \times 290 \times 1000 = 4320000 \]

Field A \( = 185000 = 1 \text{acre}, 3 \text{rods, } 16 \text{perches, for the measure thereof.} \)

Field B \( = 740 \times 500 \)

\[ 2 \times 740 \times 500 = 370000 \]

The estate, fig. 21, may be measured by a general line, with normals erected thereon, in manner following: viz.

Beginning at the southern end, a measurer takes his principal line from A towards the tree on the northern limits of his work; and at every necessary point in that line, he sets off such perpendiculars as will lead him to the corners of each field, as in the figure. The dimensions taken in each field being as here given, the content of each may be found in manner following:

The plan of the estate being obtained by these dimensions, or for lines must now be drawn in each field, dividing it into such geometrical figures as will most readily give the content; as in fig. 26.

By dividing the fields as before directed, the content of each may be found as follows:

#### HOME PADDOCK. Double areas.

#### THE GARDEN.

| Trapezoid | $f = 710 \times 140 = 121400$ |

#### THE PLANE TABLE.

Land-measuring may, in some instances, be expedited by instruments which set off lines in their relative positions, and the angles of their intersection; one of these - the convenient instruments for these purposes, are the Plane-table and the Theodolite.

The Plane-table is composed of a smooth rectangular board, commonly of about 15 inches by 12; around which is a frame, that not only serves to keep the paper smooth on which the plan is to be drawn, but, being graduated into degrees, answering to a central point in the board, the angular bearing of any two lines, issuing from the station where the instrument is placed, may readily be ascertained; or the angle itself may be drawn on the paper. — A magnetic needle and compass-box is fixed to one side of the board, which serves to point out the bearing of any line to the magnetic meridian. — There is also, a brass index-rod, having sundry scales thereon, and also perpendicular sights at the end used herewith. The whole is supported on a three-legged stand, &c. movable on a brass ball and socket.

A land-measurer having planted his Plane-table at A, one of the inner angles of the field ABCDE, fig. 27, and from some assumed point on the paper (which may be considered as his station-point on the land) directed his sight along the boundary to B, and also to C, to D, and to E, and, by measuring these lines on the ground, finding them to be as follows, viz.: AB = 665, AC = 895, AD = 1635, and AE = 580; he may make a correct plan of the field and from thence, by dividing the other lines on the plan, as herefore directed, he may calculate the content thereof.

If the other sides of the same field, viz. BC, CD, and DE, &c. (fig. 27), had been measured, either on the ground, or on the plot, the content may be found by Rule 2, for the triangle.

A measure may take his observations from a point above the middle of a field, as at A (fig. 28), and take his angles of bearing to all the corners of the field, and measure the links to each corner, and from thence find the content for, suppose the $Z. BAC = 105^\circ$.

And that the line $AC = 1700$.

#### THE THEODOLITE.

The Theodolite is a circular instrument made of brass, graduated into degrees, &c. on which is an index-limb for taking horizontal angles, surmounted with an arch for vertical angles, and a telescopic sight. It has, usually, spirit-levels to adjust it by; and a compass, with angular scales, checking the bearings by the limb: the whole placed on three legs, and a ball and socket, or half-ball and parallel plates, to set it level.

In all cases of land-measuring, where angles are required to be taken, whether horizontal or vertical, no instrument is so well adapted thereto as the theodolite; its accuracy and dispatch for exceeding all other instruments used for that purpose, especially on large estates, where varieties of boundary, as well as inequality of surface, are met with.

In a single piece of land, the angular observations may all be made from one spot in a field.

In this case, the theodolite being set at the station A, fig. 31, and properly adjusted (as hereafter described), the first observation to the picket-staff at a, was $62^\circ$, from the north towards the east, and the length of the line $AA = 660$ links.

The second observation, to $b$, between the south and east, was $158^\circ$, and the length of the line $AB = 260$ links.

The third, to $c$, between the south and west, was $200^\circ$, the length 750.

And the fourth observation, to $d$, from the north towards the west, $293^\circ$, with the length 539.

From hence, with the help of a protractor, the plan may be drawn.

It is evident, that if from the observation $I$, the plan is to be constructed, the lines as described in fig. 27, to $B$, $C$, $D$, &c. shall be drawn, and the work of the theodolite be reduced to the measurement of these lines in the actual ground. It is evident, further, that the other parts of the field may be measured as above.
SURVEYING.

that of $a$ is subtended, the $\angle aAB$ will be found as $30^\circ$.

That if from the observation of $a$, that of $b$ is subtended, the $\angle aAB$ will be found $= 48^\circ$.

And also, that if the circular complement of the observation $a$ (which is $360^\circ - 320^\circ = 30^\circ 10'$) is added to the observation $a$, the $\angle aAB$ will be found as $39^\circ 20'$.

The whole together making (as it ought) the complete circle $360^\circ$.

The content may now be computed by Rule 3.

A measure may take the angle at each corner of a piece of ground, and measure the sides as he goes on, thus:—having set the needle to its $320^\circ$, and the limb to its $360^\circ$, he found by observation at $\Theta 1$, that looking to his picket at $\Theta 2$, the limb cut $310^\circ$ from the north towards the west, and his needle $129^\circ$.—At $\Theta 2$, having directed the theodolite to the back station, his observation forward was, on the limb, $45^\circ 30'$; from south to west, and on the needle $45^\circ 30'$ also.

At $\Theta 3$, the limb was at $185^\circ$ from south to east; he need not move his needle for insetting the angular observations, and the progressive distances from station to station, and then he will find his bearings (to set off with the then left side) such short lines as the flexures or angles of boundaries may require.

The sides of the page are employed in noting down such offsets and remarks, on either hand, as may be found necessary, and also in making sketches of side boundaries, where any deviations from a straight line occur. Far the more readily sketching such side boundaries, it is necessary to begin at the bottom of the page, and write upwards.

In order to exemplify the mode of practice with this excellent instrument, we will take the estate, fig. 33, and suppose the measurer to plant his instrument in the road at $\Theta 1$, and employing it, by bearing the head thereof truly horizontal by the spirit levels and adjusting screws; and setting the index part of the limb exactly at $390^\circ$, by moving the whole head about until the $360$ in the compass-box comes to the line in the north end of the needle, the instrument will thus be completely adjusted: here he is to lock all fast by the screw under the head of the legs.

The instrument thus adjusted, the measurer sends one of his assistants forward, as far as he can conveniently measure a straight line, as at $\Theta 2$. After lining then his angle of observation by his telescope, he finds it to be $69^\circ$ from the north towards the east, which he enters in his field-book, noting it with N.E. as a memorandum on which side of the meridians. He must now fix his limb to the other part of the head, by a screw for that purpose. His chain-men having laid the line in a direction to the picket at $\Theta 2$, the instrument next line the cross head across such offsets to the right and left as may be necessary.

At his station he finds, by measuring, on the paper, in pencilled figures, that he has the general line of the road; at $30^\circ$ and also a corner of $40$ links more, and $300$ broad: on the left of his station he has an offset of $10$ links. The chain-men proceeding on their line to $300$, he finds $d$ on the right to be the breadth on that side of the road, where is a gate, and $30^\circ$; which will determine the breadth of the road at that spot. At $400$ he will find $10$ on the right, and $20$ on the left, to be the breadth. At $700$ (the end of that line) he will find $100$ on the left, and $15$ on the right, to be the breadth; where also he will find a small road branch off to the right. Thus is the first station completed, and the cross head on the. 

To this spot (which is his second station) he brings his theodolite, and after setting it level, unlocks the under screw and turns the whole head about, through the telescope, behaves the back picket or station-staff. Here again, locking the head of his theodolite, he must unscrew the limb, and turn it about until, through the telescope, he has a view of the picket at $\Theta 9$; the angle to which he will find to be $55^\circ 10'$ from the north to the eastward, which he will enter in his field-book. Measuring on $\Theta 9$ is a bearing of the fence, and the theodolite, he has a view of the picket at $\Theta 9$; the angle to which he will find to be $25^\circ 10'$ from the north to the eastward, which he also enters in his field-book.

Supposing the lines were found to be $1000$ links, $400$ links, $160$ links, and $200$ links, the plan may be made, and the content found by the scale.

In extensive concerns, where all the fields in an estate are to be measured, the same method with suitable instruments must be taken with the theodolite, and the proceedings carefully noted down in the field-book, the pages of which are divided into three parts of an inch column being for insetting the angular observations, and the progressive distances from station to station, and then he will find his bearings (to set off with the then left side) such short lines as the flexures or angles of boundaries may require.

The sides of the page are employed in noting down such offsets and remarks, on either hand, as may be found necessary, and also in making sketches of side boundaries, where any deviations from a straight line occur. Far the more readily sketching such side boundaries, it is necessary to begin at the bottom of the page, and write upwards.

In the field-book for the quantity of the $\angle \Theta 3$, which, in the present case, is stated to be $69^\circ 0'$ north-westly. Look for this degree, on the circular edge of the protractor, and on the paper make a mark, with a fine pencil, running parallel to the base line.

On the left of the field-book for the $\angle \Theta 3$, which, in this case, is $25^\circ 10'$, where there is a mark, as before.

Thus do with all the other $\angle s$, until you come to the one nearest the eastward, and make a mark to close on some former part of the work.

All the angles being thus prick'd off, remove the protractor.

Consider wherefrom the beginning of the work should be pricked, so that the whole may come within the compass of the paper laid down; and there make a mark, noting it as $\Theta 1$, the beginning of the plot.

Lay down the parallel ruler from the central point where the protractor lay, to the mark on the pencilled circle denoted $\Theta 1$. Move the fore edge of the parallel ruler until it touches the point determined on for the beginning of the plot.—From thence draw an oblique or diagonal line (as mentioned, i.e. in this case, from the north to the eastward) about the length of the whole line of this $\angle$, drawn across the line of the plot, and back to the point on the compass circle denoted $\Theta 1$, as shown in the field-book, note that on the line marked at $10$ links, is the boundary-line of that side, where also is a
SUS, hog, a genus of quadrupeds, of the order Blumin. The generic character is, front teeth in the upper jaw four, converging, in the lower jaw six; projecting canine teeth, or tusks, in the upper jaw two, rather short; in the lower jaw two, long, exserted; snout truncate, prominent, movable; feet calve. The genus is in points of some an ambiguous nature, being allied to the porca, by its cloven hoofs, and to the fera, in some degree, by its teeth; yet differing widely from both in many respects. The internal structure of the feet also approaches to that of the digitated quadrupeds, while that of some other parts is peculiar to this genus alone. It may, therefore, be allowed to form at once a link between the cloven-footed, the whole hoofed, and the digitated quadrupeds.

1. Sus scrofa, common hog. The wild boar, the stock or original of the common hog, is a native of almost all the temperate parts of both Europe and Asia, and is also found in the upper parts of Africa. It is a stranger to the arctic regions, and is not indigenous to South America.

The wild boar inhabits woods, living on various kinds of vegetables, viz., roots, mast, acorns, &c. &c. It also occasionally devours animal food. It is, in general, considerably smaller than the domestic hog, and is of a dark brindled grey colour, sometimes blackish; but when only a year or two old, is of a pale rufous or dull yellowish brown cast; and when quite young, is marked by alternate dusky and white stripes disposed longitudinally on each side the body. Between the bristles, next the skin, is a finer or softer hair, of a kind of woolly or curly nature. The snout is somewhat longer in proportion than that of the domestic animal; but the principal difference is in the superior length and size of the tusks, which are often several inches long, and are capable of inflicting the most severe and fatal wounds.

The hunting of the wild boar forms one of the amusements of the great in some parts of Germany. Pork hunters will undertake a chase of some difficulty and danger; not on account of the swiftness, but the ferocity of the animal.

As the wild boar advances in age, after the period of two or four years, he becomes less dangerous, on account of the value of his tusks, which turn up, or make so large a curve or flexure, as often to render it impossible to thrust his tusks to the wound.

To describe particularly the common or domestic hog would be superfluous. It may be sufficient to observe, that this animal principally differs from the wild boar, in having smaller tusks, and larger ears, which are also somewhat pendant, and of a more pointed form. Of all quadrupeds the hog is the most graceful in his manners, and has therefore been properly uniformly considered in all nations as the emblem of iniquity. The Jews were strictly enjoined not to cut its flesh; and in many parts of the world, a similar prohibition is still in force; since the Mahometans agree in this respect with the Mosiac institution. In most parts of Europe, on the contrary, it constitutes a principal part of the food of mankind. This animal is of a remarkably prolific nature, and is sometimes known to produce as many as twenty at a birth.

The hog was unknown in America, on the discovery of that continent; but since its introduction, appears to flourish there as much as in the old world. The varieties into which the hog occasionally runs, chiefly relate to the colour and form of its ears. The so-called Chinese hog is of a very small size, with a pendulous belly: its colour is commonly black, and the skin often nearly bare, or less hairy than in the European kinds.

The variety called the Guinea hog is distinguished by having a smaller head than the common hog, with longer, slenderer ears, and naked tail reaching to the ground. Its colour is rufous, and its hair shorter, and finer than in other kinds. It is said to be most common in Guinea, and is considered by Linnaeus as a distinct species, under the title of Sus porcus.

But the most remarkable variety of the hog is that in which the hocks are entire and undivided. This is a mere accidental variety, which, is, however, observed to be more common in some countries than in others, and is according to Linnaeus, not unfrequent in the neighbourhood of Upsal in Sweden. It has been noticed by Aristotle and Pliny, and is said by the former to have been most common in Iliyria and Paroia.

The age of the domestic hog is said to extend from fifteen to twenty-five years, or even more.

2. Sus Ethliopicus, Athiopian hog. This animal is very much allied in its general appearance to the common hog, but is distinguished by a pair of large, flat, semicircular lobes or waffles, placed beneath the eyes: the snout is also of a much broader form, and is very strong and callous; its ears are large, and very slightly pointed: the tusks in the lower jaw are rather small; but those in the upper jaw are large, sharp, curved, and in the old animal bend upwards in a semicircular manner towards the forehead: there are no fore teeth; their place being supplied by very hard gums: the skin of the face, immediately below the eyes, or above the broad lobes before mentioned, is loose and wrinkled, and on each side the mouth is a callous protuberance. The body is of a strong form: the tail slender, slightly flattened, and thinly covered with scattered hairs. The general color of the whole animal is dusky or black.

This species is a native of the hotter parts of Africa, occurring from Sierra Leone to Congo, and to within about two hundred leagues of the Cape of Good Hope. It also occurs in the island of Madagascar.

It is a fierce and dangerous animal, and is said to reside principally in subterraneous recesses which it digs with its nose and hoofs. When attacked or pursued, it rushes on its adversary with great force; and strikes, like the common boar, with its tusks, which are capable of inflicting the most tremendous wounds.

3. Sus Africanus, Cape Virgin hog. The Cape Virgin hog has been generally confounded with the former species; but which, however, it appears to differ very considerably in having a head of a much longer and slenderer form, with the upper jaw extending beyond the lower. In the upper jaw are also two or three cutting teeth, and the lower tusks are very large and thick, but those of the former jaw much larger than those of the upper. The ears are rather narrow, pointed, and tufted.

SURVIVORSHIP. See LIFE ANNUL.
with long bristles or hairs: the whole body is also covered with long, weak, or fine bristles, of which those on the shoulders, belly, and thighs, are much longer than on other parts: the tail is tufted, and terminates in a long tuft of thick black hair. The color of the hair is a palish brown. Its general size is that of a common hog, but it is said sometimes to be found far larger. It is a native of Africa, extending from Cape Verde to the Cape of Good Hope. See Plate Nat. Hist. fig. 333.

4. Sus babouria. The babouria is nearly of the size of a common hog, but of a somewhat longer form, and with more slender limbs, and is covered, instead of bristles, with fine, short, and somewhat woolly hair, of a deep-brown or blackish color, interpersed with a few bristles on the upper and hinder part of the back. It is also distinguished by the very extraordinary position and form of the upper tusks, which, instead of being situated in the front, on the edge of the jaws, as in other animals, are placed externally, perforating the skin of the snout, and turning upward toward the forehead; and as the animal advances in age, become so extremely long and strong that the forehead continues to curve downward by which means they must of necessity lose their power as offensive weapons: the tusks of the lower jaw are formed as in the rest of the genus, and are very long, sharp, and curved; but not of equal magnitude with those of the upper. The upper tusks are of a fine hard grain, like that of ivory: the eyes are small; the ears somewhat erect, and pointed; the tail long, thick, and tufted, at the head with long hairs.

The babouria is a gregarious animal, and is found in large herds in many parts of Java, Ambonea, and some other Indian islands. Their food is entirely of a vegetable nature, and they often feed on the leaves of trees. When sleeping or resting themselves in a standing posture, they are said often to hook or support themselves by placing the upper tusks across the lower branches of the tree. When alarmed they will often plunge into a river, or even into the sea, near, and can swim with great vigour and facility, and to a vast distance. The voice of the babouria is said to resemble that of the common hog, but it is considerably shorter and weaker, and is not a strong or loud growling note. It is sometimes tamed by the inhabitants of the Indian islands, and the flesh is considered as a wholesome food. See Plate Nat. Hist. fig. 333.

5. Sus tajanus, pecary. The pecary is the only animal of this genus that is native of the new world, where it is chiefly found in the hottest regions. Its size is considerably smaller than that of a common hog, and it is of a short compact form. The whole animal is thickly covered, on the upper parts, with very strong dark-brown or blackish bristles, each marked by several yellowish-white rings; so that the colour of the whole appears dotted with minute freckles or specks, and round the neck is generally a white border or collar. The head is not so large; the snout long; the ears short and upright; the body nearly naked: there is no tail, and at the lower part of the back, or at some little distance beyond the rump, is a glansular organ surrounded by strong tubercles, in a somewhat radiated direction. From the orifice exudes a strong-smelling fluid, and this part has been supposed to be the navel of the animal: the tusks in this species are not very large.

The pecary is a gregarious animal, and in its wild state is fierce and active. It sometimes destroys the crops of the country, with great vigour, and often destroying the dogs which are employed in its pursuit. It feeds not only on vegetable substances, but occasionally on animals of various kinds, and is particularly an enemy to snakes and other reptiles; attacking and destroying even the rattlesnake, without the least dread or inconvenience, and dexterously skimming it, by holding it between its feet, while it performs that operation with its teeth. It is also remarkable that the common hog, when translated to America, will attack and destroy the rattlesnake. The pecary is considered as an agreeable food; but the dorsal gland must be cut away as the animal is killed; otherwise the whole flesh would be infected with an unpleasant flavour. See Plate Nat. Hist. fig. 336.

SUSPENSION, or Points of Suspension, in mechanics, are those points in the axis or beam of a balance, wherein the weight is supplied, or from which it is suspended.

In a law sense, suspension is a species of censure, whereby ecclesiastical persons are forbidden to exercise their office, or to take the profits of their benefices; or when they are prohibited in both of them for a certain time, either in whole or in part. Suspension is also said to relate to the faulty, viz. suspension ad injuriam ecclesiae, i.e. from hearing divine service.

SUTURE. See Surgery.

SWARETZIA, a genus of the class and order polyandria polyandria. The calyx is four-leaved; petals single, lateral, flat; legumone-cell, two-valved; seeds globular. There are six species, trees of the West Indies.

SWEARING, an offence punishable by several statutes: thus stat. 6 and 7 Will. III, cap. 11, or lib.) that if any person shall,, to any person, servant, or common soldier, he shall forfeit 1s. to the poor, for the first offence, 2s. for the second, &c.; and any person not a servant, &c. forfeits 2s. for the first offence, 4s. for the second, 6s. for the third, &c. to be levied by districts of goods.

SWEAT. See Perspiration.

SWEATING-SICKNESS, a disease which appeared first in England, in the year 1483. It seized different patients in different manners; for in some it first appeared with a pain in the neck, scapula, legs, or arms; whilst others perceived only a kind of warm vapour, or flatulence, running through those parts. And these symptoms were suddenly succeeded by a profuse sweat, which the patient could not account for. The internal parts became first warm, and were soon after seized with an incredible heat, which thence diffused itself to the extremities of the body. An intolerable thirst, and indisposition of the stomach, liver, and stomach, were the next symptoms, which were succeeded by an excessive head-ache; a delirium, in which the patient was very talkative; and after these, a kind of external, irresistible necessity of sleeping. For preventing this disease, temperance was ordered, and the choice of salutary aliments and drinks, and no crude pot-herbs nor salt-laffs to be used.

SWEET, in the sea-language, is that part of the mouth of a ship that begins to creak in at the rump-heads: also, when the hawser is dragged along the bottom of the sea, to recover any thing that is sunk, they call this action sweeping for it.

SWEETS, in the wine trade, denotes any vegetable substance, especially raisins, or other foreign or domestic fruit, which is added to wines, with a design to improve them.

SWEERTIA, marsh gentian, a genus of plants belonging to the class of peonies, and to the order of gentianaceous. See Plate Nat. Hist. fig. 336.

The perenn is a native of England. It is distinguished by radical oval leaves. It flowers in August.

SWETIENIA, mahogany, a genus of plants belonging to the class of deccamers, and to the order of malvaceous. They are large trees of the Cape of Good Hope, and the Cape of Good Hope.

It abounded formerly in the low lands of Jamaica, but now is found only on high hills and places difficult of access. It thrives in most soils, but varies in texture of growth and grain according to the nature of the soil. On rocks it is of a smaller size, but very hard and heavy, of a close grain, and beautifully polished; while the produce of the low and richer lands is observed to be more light and fine, a paler colour, and open grain; and that of mixed soils to hold a medium between both. The tree grows very full and straight, and is usually four feet in diameter; the flowers are of a yellow or saffron colour, and the fruit of an oval form, and about the size of a turkey's egg.

The wood is generally hard, takes a fine polish, and is found to answer better than any other soot in all kinds of cabinet-ware. It is now universally esteemed, and sells at a good price. It is a very strong timber, and answers very well in beams, joists, planks, boards, and shingles; and has been frequently put to those uses in Jamaica in former times. It is said to be used in ship-building; a purpose for which it is remarkably adapted, it not only costly, but very durable, capable of resisting gun-shots, and burying the shots without splintering.

The seed-vessel are of a curious form, consisting of a large cone splitting into five parts, and disclosing its winged seeds, disposed in the regular manner of those of an acorn. The seeds being winged, are dispersed on the wind, or falling into the chinks of the rocks, strike root; then creep out on the surface, and seek another chink, into which they creep and swell...
each a size and strength, that at length the species, and is forced to admit of the root's deeper penetration; and with this little mitre the tree increases to a stupendous size few years.

WIMMING, the act of sustaining the head in water, and of moving in it, in which on the air-bladder and fins of fishes bear a considerable part. See AIR-BLADDERS.

WIMMING, as applied to human beings, is the art of balancing the body on or near the surface of the water, and of making a passage through it; an art so useful, we might so necessary, that every young person ought to be instructed in it; and as it is also a wholesome and pleasant exercise, it ought to be regularly taught at schools, as well as other athletic exercises.

The art of swimming is so antient, that we can no accounts of its origin in the history of nations; nor are there any nations so barbarous but that swimming is known and practiced among them, and that in greater perfection than among civilized people. It is a proc. therefore, that the art, though not absolutely natural, will always be acquired by people in a savage state, from imitating the actions of the animals, most of whom swim naturally.

The cause of so much difficulty in this is, the common practice in the case. Very expert swimmers have recommended to those who wish to learn to imitate the motions of the frogs in moving through the surface of the water.

The art of swimming depends entirely on keeping the body in a proper balance, this is easily and almost insensibly acquired.

The great obstacle is the natural buoyancy of which people are in possession; this it is impossible to overcome by any exertion of the body. An attempt to go into water.

With regard to the real danger of drowning, it is a little; and on insubstantial occasions arises entirely from the above mentioned, as will appear from the wing observations by Dr. Franklin:

1st. That though the legs, arms, and head, human body, being solid parts, are specifically heavier than fresh water, the trunk, particularly the upper part, is its soundness, is so much lighter than water, that the whole of the body, taken together, is too light to sink wholly under water, some parts will come above until the lungs are filled with water; which happens from water into them instead of air, when pressed in the fright attempts breathing while mouth and nostrils are under water.

2dly. That the legs and arms are specially lighter than salt water, and will be supped by it; so that a human body could sink in salt water though the lungs were as above, but from the greater specific gravity of the body, the water will have the effect of increasing the buoyancy of the body.

That therefore a person throwing himself in his back in salt water, and extending arms, may easily lie so as to keep his mouth nostrils free for breathing; and by a small motion of his hands may prevent turning, if the motion of arms is not obstructed.

4thly. That in fresh water, if any man was himself on his back near the surface, cannot long continue in that situation, but proper action of his hands on the water.

G.J. Balances not such action, the legs and looser of the body will gradually sink till he comes into an upright position; in which he will continue suspended, the hollow of the breast keeping the head uppermost.

5thly. But if in this erect position the head is kept upright above the shoulders, and when we stand on the ground, the immersion will, by the weight of that part of the head that is out of the water, reach above the mouth and nostrils, perhaps a little above the eyes. It is possible that a man cannot long remain suspended in water with its head in that position.

6thly. The body continued suspended as before, and upright, if the head is leaned quite back, so that the face looks upwards, all the weight of the part of the head being then under water, and its weight consequently in a great measure supported by it, the face will remain above water quite free for breathing, will rise an inch higher every inspiration, and sink as much every expiration, but never so low that the water may come over the mouth.

7thly. If therefore a person unacquainted with swimming, and falling accidentally into water, could have presence of mind sufficient to avoid struggling and plunging, and to let the body take this natural position, he might expect that his arms, if no help would come; for as to the clothes, their additional weight while immersed is very considerable, the water supporting it; though when he comes out of the water, he would find them very heavy indeed.

The method of learning to swim is as follows: The person must walk into water so deep that it will reach to the breast. He is then to lie down gently on the belly, keeping the head and neck perfectly upright, the breast advancing forward, the thorax inflated, and the back bent; then withdrawing the legs from the bottom, and stretching them out, strike the arms forwards in unison with the legs. Swimming on the back is somewhat similar to that on the belly, with this difference; that the legs are here chiefly employed to move the body forwards, and the arms are often unemployed, for the progressive motion is derived from the movement of the feet.

In diving, after the plunge, a person uses the same action as before; only the head is bent downwards; and whenever he chooses to return to his former situation, he has nothing to do but bend back his head, and he will immediately return to the surface.

It is very common for novices in the art of swimming to make use of cords or bladders to assist in keeping the body above water. Some have utterly condemned the use of these; Dr. Franklin, however, allow that they may be of service for supporting the body while one is learning what is called the stroke, or that manner of drawing in and striking out the hands and feet that is necessary to produce the progressive motion. But (says he) you will be no swimmer till you can place confidence in the power of the water to support you: I would therefore advise the acquiring of that confidence in the first place, especially as it is by a little of the practice necessary for that purpose, have insensibly acquired the stroke, taught in a manner by nature.

The practice I mean is this: choosing a place where the water descends gradually, and walk cooly into it till it is up to your breast.
SYLOGISM, in logic, an argument or term of reasoning, consisting of the two premises and the conclusion. See LOGIC, MODE, &c.

SYMPHONIA, a genus of plants of the class of monadephia, and order of pentandria. There is one pit. The corolla is globular, the berry-like. There is only one species yet discovered; the globulifer, a tree of Surinam.

SYMPHONY, in music, properly denotes a concomance or concert of several sounds agreeable to the ear, whether vocal or instrumental, called also a harmony. See MUSIC.

SYMPHYSES, in anatomy, one of the kinds of junctures of articulation of the bones. See ANATOMY.

SYMPHYTUM, conyfrey, a genus of plants of the class of pentandria, and order of monadephia; and in the natural system ranking under the 41st order, superflora. The limb of the corolla is tubular and ventricose, and the throat is shut with avul-shaped rays. There are three species; the officinale, tuberosum, and orientale. The officinale is a British plant, the stem is about two feet high, round, branched, green, and rough. The radical leaves are large and rough; those on the stalk are decurrent, and alternate. The flowers grow on loose spikes, and are either of a yellowish or purple colour. It grows on the banks of rivers, and flowers from May to October.

SYMPLOCOS, a genus of plants of the class of polyadephia, and the order of polyandria; and in the natural system ranking under the 25th order, superflora. The limb of the corolla is tubular and ventricose, and the throat is shut with avul-shaped rays. There are three species; the officinale, tuberosum, and orientale. The officinale is a British plant, the stem is about two feet high, round, branched, green, and rough. The radical leaves are large and rough; those on the stalk are decurrent, and alternate. The flowers grow on loose spikes, and are either of a yellowish or purple colour. It grows on the banks of rivers, and flowers from May to October.

SYNCOPE, fainting. See MEDICINE.

SYNOCTE, in grammar, an elision or repetition of letter or syllable out of the middle of a word, as calidus for calidus, aspers for asperis, &c.

SYNGENESIS. See BOTANY.

SYNGNATHIUS, pipefish, a genus of fishes of the order osteichthyes; the generic character is, snout subcylindrical, with terminal mouth; body lengthenedit, jointed, mailed; ventral fins none.

1. Syngnathus acus, great pipefish. The fishes of the present genus are inhabitants of the sea, and are observed to frequent the shallower parts near the shore, feeding on the smaller worms and insects; they are easily distinguished by their slender habit, and angular jointed body. The syngnathus acus or great pipefish is usually seen of the length of twelve or fifteen inches, but is sometimes found, especially in the northern parts of the northern seas, of a greater length, measuring from two to three feet: it is of an extremely slender form, gradually tapering towards the extremity, and is of a pale yellowish-brown colour, varied through its whole length with broad alternate zones of a deeper or olive brown, with a few smaller variations intermixed: the scales or lamina with which the joints of the body are covered, appear, if narrowly inspected, to be finely radiated from the centre by numerous lines or streaks: the dorsal fin is placed but two-thirds of the body; the head is larger than the tail, and is thin, tender, shalhown; and the fish can be shelled with ease. The pectoral fins small, and slightly rounded, and the tail of similar shape and size. In spring, as in others of this genus, the ova are found lying in a longitudinal channel or division at the lower part of the abdomen, and are large in proportion to the size of the animal; from these are hatched the young, completely formed. Native of the European seas.

2. Syngnathus hippocampus, sea-horse pipefish. A fish of a highly singular appearance: general length from six to ten inches; body much compressed; colour greenish brown, varied with darker and lighter species; head large, thickish, and bent on the upper part, as well as along some of the first joints of the body, with several small, weak, lengthened spines or cirri, which are sometimes slightly raminated: snout slender: neck contracting suddenly beyond the head; body rather short, and contracting gradually towards the tail, which is long, quadrangular, and terminates in a naked or inflated tip. In its dry or contracted state this animal exhibits the fancied resemblance from which it takes its name, but in the living state its appearance is somewhat less striking, the head and tail being carried nearly straight. It is a native of the Mediterranean, Northern, and Atlantic seas.

SYRINGOTON, in music, a kind of sonata, a kind of sonata, consisting of two parts; the upper part is a melody, the lower a diminution of the melody. See SYMPHONY.

SYRINGOTON, in medicine, a kind of sonata, a kind of sonata, consisting of two parts; the upper part is a melody, the lower a diminution of the melody. See SYMPHONY.

ed it into a fourth on each side, and a tone of the middle. This system did not, however, continue long confined to so few nations. Classical authors, as Plato, Pliny, and others, have left accounts of the system. Thus, for instance, Boethius informs us, added a fifth to the Pythagorean scale; Hyginus a sixth; Serapion a seventh, equal the number of the planets; and there is an eighth. But Pliny gives a different account of the progression of the ancient system; according to that writer, Teredo added three chords to the tetrachord, and Diocles joined to it an eighth, Tithonos a ninth.

Whichever of these accounts may be the true one, it seems pretty certain that the system of the Greeks was gradually extended, both upward and downward; and that it attained and exceeded the limits of the bis diapason, or double octave, an extent which they called systema perfectum, maximum, immensus, the great system, the perfect system. This entire system was composed of four tetrachords, three conjoint and one disjunct, and the chord called proslamanoskeion, which was added below these tetrachords to complete the double octave.

This general system of the Greeks remained nearly in this state till the eleventh century, when Guido made a considerable change, by adding a new chord below, which he called hypodiapasonmononomos; also a fifth tetrachord above, or tetrachord of the sur-sharp; and substituting hexachords in the place of the ancient tetrachords. Since the time of Guido, the general system has again been greatly extended, and divided into octaves; and which has long been adopted throughout Europe, and which the ear certainly recognises as the most natural of all possible partitions of the great scale of sounds.

SYSTOLE. See Anatomy.

SYZYGY. See Astronomy.

The nineteenth letter of our alphabet.

Amongst the antients, T. as a numeral, stood for one hundred and sixty; and with a bar at top, thus T6, it signified one hundred and sixty thousand. In music, T stands for tun, all, or altogether.

TABANUS, a genus of insects of the order Diptera. The generic character is, mouth armed into a flabby proboscis, two lips; root of winged by two pointed alpi, placed on each side of, and parallel to, the proboscis. There are 53 species.

The largest of the British species is the tabanus bovinus of Linnæus, having the appearance of a very large grey or pale-brown fly, often measuring near an inch in length, and marked down the back by a series of large, whitish, triangular spots, pointing forward; on each side also is an approach to a similar appearance, though fainter than that of the dorsal row. This insect, like the rest of the genus, is seen during the middle and the decline of summer; generally in the hottest part of the day. It is extremely troublesome to cattle, piercing their skin with the lancets of its trunk, and making its blood in such a manner as to cause considerable pain. It proceeds from a large dusty-yellowish larva, nearly resembling that of a tipula, and marked by transverse black or streaks. It resides under ground in moist meadows, &c. and changes to a cylindrical brownish chrysalis, with a roundish or very slightly pointed extremity; out of which, in the space of a month, proceeds the perfect insect. See Plate Nat. Hist. fig. 388.

2. Tabanus tropicus is of a smaller size than the preceding, and of a brown colour, with the sides of the abdomen bright ferruginous. It is a less common species than the former.

3. Tabanus pluvialis is of the size of a window-fly, but of a somewhat longer shape in proportion; and of a yellowish-brown colour. It is provided, with the wings of a similar cast, but marbled or variegated with very numerous whitish specks: this is a very troublesome insect during the latter part of summer, fastening on the legs, hands, &c. and causing considerable pain by the puncture of its proboscis; which is observed to be peculiarly teasing on the approach of rain.

4. Tabanus cacatius is an insect of singular beauty. It is of the size of a common window-fly, and of a yellowish-brown colour, varied with back; the wings are transparent, and marked by large black bands or patches, and the eyes are of the most vivid or lucid green, marbled with black spots and streaks. It is by no means uncommon during the autumnal season.

TABBY, in commerce, a kind of rich silk, which has undergone the operation of tabbying. See the next article.

TABBYING, the passing a silk or stuff through a calender, the rolls of which are made of iron or copper, variously engraved; which bearing unequally on the stuff, renders the surface unequal, so as to reflect the rays of light differently, making the representation of waves thereon.

TABELLA, TABLE. See Pharmacy.

TABERN.EMONTANA, a genus of plants of the class of pentaeridia, and order of monogynia; and in the natural system arranged under the 30th order, corticae. There are two horizontal folioles, and the seeds are immersed in pulp. There are 19 species, all of forest.

TABLES DORSALIS. See Medicine.

TABLE, in perspective, denotes a plane surface, supposed to be transparent, and perpendicular to the horizon. It is always imagined to be placed at a certain distance between the eye and the objects, for the objects to be represented thereon by means of the visual rays passing from every point thereof through the table to the eye; whence it is called perspective-plane.

TABLES, leaves of the twelve, were the first laws of the Romans; thus called either because the Romans then wrote with a style on thin wooden tablets covered with wax, or rather, because they were engraved on tablets, or plates of copper, to be exposed in the most noted part of the public forum. After the expulsion of the kings, as the Romans were then without any fixed or certain system of law, at least had none ample enough to comprehend the various cases that might fall between particular persons, it was resolved to adopt the best and wisest laws of the Greeks. One Hermomodo was first appointed to translate them, and the decemviri afterwards compiled and reduced them into ten tables. After much care and application, they were at length enacted and confirmed by the senate and an assembly of the people, in the year of Rome 339. The following year they found something wanting in them, which they supplied from the laws of the former kings of Rome, and from certain customs which long use had authorised; all these being engraved on two other tables made the law of the twelve tables, so famous in the Roman jurisprudence, the source and foundation of the civil or Roman law.

TABLE, among the jewellers. A table-diamond, or other precious stone, is that whose upper surface is quite flat, and only the sides cut in angles; in which sense a diamond cut tablewise, is used in opposition to a rose-diamond.

TABLE, in mathematics, systems of numbers calculated to be ready at hand for the expediting astronomical, geometrical, and other operations; thus we say tables of the stars; tables of sines, tangents, and secants; tables of logarithms, rhumbs, &c. sexagesimal tables.

TACAMAILACA. See Populus, and Resins.

TACCA, a genus of the class and order hexadriata monogynia. The cal. is six-part.
TACT, in a ship, a great rope having a
wale-knot at one end, which is seized or fas-
cued into the clew of the sail; so is recked
first through the chesstrees, and then is
brought through a hole in the ship’s side.
Just as the sail is carried forward the clew of
the sail, and to make it stand close by a wind;
and whenever the sails are thus trimmed, the
main-tack, the fore-tack, and main-ten, are
brought close by the board, and hauled as
much forward as they can be.
TACK-ABOUT, in the sea-language, is to
turn the ship about, or bring her head about,
so as to lie the contrary way.
TACKLE, or Tackling, among seamen,
designs all the ropes or cordage of a ship,
used in managing the sails, &c.
A more
restrained sense, tackles are small ropes running
in three parts, having at one end a pendant and a block; and at the other end a block and a hook, to hang goods upon that are to be carried into the ship or out of it.
TACTICS, in the art of war, is the
method of disposing forces to the best advantage
in order of battle, and of performing the several
military motions and evolutions. See WAR, art. 2.
Tactics, in the military art, a word
derived from the Greek, signifying order. Tac-
tics consist of a knowledge of order, disposi-
tion, and formation, according to the exigency
of circumstances in warfare operations.
General tactics are a combination or union of
first orders, out of which others grow of a
more extensive and complicated nature, to
suit the particular kind of contest or battle
which is to be given, or supported. Let it
not, however, be inferred from this, that evolu-
tions and tactics are one and the same.
They are closely connected, but there is still
a discernible difference between them.
Tactics may be comprehended under order and
disposition; evolution is the movement
which is made, and eventually leads to order.
The higher branches of tactics should be
thoroughly understood by all general officers;
but it is sufficient for inferior officers and
soldiers to be acquainted with evolutions.
Not that the latter are beneath the notice of
general officers; but that having already
acquired a knowledge of them, they ought to
direct their attention more immediately to
the former, carefully retaining at the same
time a clear apprehension of every species of
military detail, and consequently obviating the
many inconveniences and embarrass-
ments which occur from orders being awk-
awardly expressed by the general, and of
course ill understood by the inferior officer.
It may be laid down as a certain rule, that
unless a general officer makes himself ac-
quainted with all regular movements and dis-
positions, he preserves the necessary recol-
lections, it is morally impossible for him to
be clear and correct in his general arrange-
ments. Of all mechanical operations, found-
ad upon given principles, the art of war is
certainly the most complex, the most
elaborated, and the most capable of improve-
ment. Almost every other science and art
are comprehended in it; and it should be
the subject matter, the chief study, and the
ultimate end of a general’s reflections. He
must not be satisfied with a limited concep-
tion of its various branches; he should go
deply into all its parts, be aware of its mani-
fold changes, and know how to adapt move-
ments and positions to circumstances and
places.
It will be of little use to a general to have
formed vast projects, if, when they are to be
executed, there should be a deficiency of
ground; if the general movements of the
jury should be embarrassed by the irre-
regularity of some particular corps, by their over-
lapping each other, &c.; and if, through the
tardiness of a manoeuvre, an enemy should
have time to render his plan abortive by a
more prompt execution. A good general
must be aware of all these contingencies, by
making himself thoroughly master of tactics.
The Prussian tactics under Frederic the
Great, had for their principal object to con-
strain the French to diminish and cleave by
the weight of an enemy, not at one and the same
time, but one after another: whereas the tactics
which have been uniformly pursued by the
French, since the commencement of their
revolutions, and which have been promul-
gated as a universal principle, to attack all points with divided
forces, at one and the same time.
We thus
see, that the principles of extension have
been as much followed by the latter, as those
of contraction were studiously adhered to by
the former.
Tactics of Europe. The following obser-
vations respecting the tactics of Europe,
which we extract from a book entitled the
Elementary Principles of Tactics, page 137,
may not be uninteresting to our military
readers: In the time of the Romans, the Gauds
and other nations on the continent fought in the
phalanx order; it is this order which still pre-
vails throughout all Europe, except that it is
deficient in the advantages and utility which
Polybius ascribes to it, and is injured and
disgraced by defects unknown to the ancient
phalanx.
In Turenne’s days, troops were ranged 8
deep, both in France and Germany. Thirty
years after, in the time of Puysen, the
ranks were reduced to 5; in the last Flanders
war to 4; and immediately after to 3; at pre-
sent the ranks are reduced to 2.
This part of the progression from eight
to three being known, we easily conceive how
the files of the phalanx have been dimin-
ished from sixteen to eight in the ages preceding
Turenne. It is to be presumed, that this depth
was considered as superfuous; and it was
judged necessary to curtail it, in order to
extend the front. However, the motion is
of very little consequence, since we are now
reduced to three ranks; let us therefore en-
deavour to find out what qualities of the pha-
lanx have been preserved, and what might
have been added to it.
To shew that we have preserved the de-
fects of the phalanx; in the first place, we state
that two bodies of troops, one of eight thousand
men, ranged as a phalanx, sixteen deep; the
other a regiment of three battalions, consist-
ing only of fifteen hundred men, drawn up in
three lines nine deep.
To shew, that these two bodies shall be perfectly equal and alike
in extent of front, and shall differ in nothing
but in the depth of their files; the in-
conveniences and defects, therefore, occa-
sioned by the number of their fronts, are equal
in both troops, though the numbers are
very different; hence it follows, that in Eu-
rope, the essential defects of the phalanx are
preserved, and its advantages lost.
Let us consider the files of the body of eight thousand
be afterwards divided, and let it be reduced
to three in depth, its front will then be found
five times more extensive, and its depth five
times less; we may therefore conclude, that the
defects of the phalanx are evidently multi-
plied, and the advantage of the other
reduced to a very limited extent.
These are the two principal causes of the
little solidity or depth given to our batta-
lions.
We have now seen, that the defects of
the phalanx were transferred to our European
discipline, and its advantages and perfection
infinitely diminished. Our regulations are
therefore, much inferior to the phalanx, and
have nothing but the single effect of fire-arm
to counterbalance all its advantages.
To effect, however, of fire-arms, is an artificial
power, and does not originally belong to,
the manner of disciplining troops, the sole aim
of which should be to employ man’s natural ac-
tion. It is man, therefore, and not this fire-
which is to be considered as the principal
agent; and hence we infer, that the method
is very much inferior to the phalanx;
and still more to the Roman arrangement
which we have considered.
The light troops of both these people were
much heavier than our battalions, and had
more power and solidity for a shock or con-
front. However, the Roman discipline, notw.
withstanding its superiority, is not calculated
for our times; because, as we are obliged
to engage at a distance, ours, by its cannon
would destroy the Grecian order of battle in
a very short time, and would be exposed to
loss much less considerable itself, supposing
the artillery were placed on both sides
we should then, in order to perfect our ar-
rangements, endeavour to procure them all
the advantageous qualities of the legionary
regulations, as the only means of giving them
the superiority.
Many people are of opinion, that we imi-
itate the Romans; and that we give battle ac-
cording to their system, because our troops
are drawn up in lines, some of which are
multiplied. But it has been proved, that three
battalions have the same front, and the same
inconveniences, that eight thousand men, ranged in the pha-
lanx order. Our lines are formed by brigades,
regiments, or battalions, and the distance of one
corps for the other is equal to the front.

---

764 TAC TAC TAC
c; con. six-pasted, inserted into the ca.;
stigma stellate; berry dry, hexagonal, &c.
There is one species, a herb of the East
Indies.

TACHOGRAPHY, the art of writing
fast o of short hand; of which authors have
invented several methods. See STENOGRA-
PHY.

TACK, a round, long, pointed, and
hardened point, which fastens the needle to
the fabric; a kind of tack for the upper
part of the head, the lower part of the
head, or the ear; the first and second
point of a shoemaker’s tool; and the
first point of a single-pointed tool.

TACKLE, Tack-about, TACK,
TACKLE, Tack-about, TACK,
TACKLE, Tack-about, TACK,
TACKLE, Tack-about, TACK,
of one of those corps: so that those lines, both full and vacant, are composed of detachments equal in front and in defects; each has a phalanx of six, eight, or twelve thousand men. Our orders of battle, consequently, can be no more at most than that kind of medium between those of Greece and Rome.

Tactics, maritime, or manoeuvres at sea. With respect to naval tactics, or the art of fighting at sea, it is confessedly less antient than tactics on shore; but what is generally called海军 is in truth Mankind. Mankind were accustomed to contend for the possession of territory long before they determined on, or even dreamed of, making the sea a theatre of war and bloodshed.

Setting aside the many fabulous accounts which are extant concerning naval tactics, we shall remain satisfied with what has been transmitted to us by the Roman writers of the fifth and sixth centuries of that republic. We shall there find specific details of the different preparations which were practised in the sea during the Punic war. In those times naval armaments began to be regularly fitted out; ships of different forms and sizes were constructed; and certain offensive and defensive machines, or what served as a species of artillery, were placed upon them. They had already been drawn out according to system; being divided into certain proportions which were then called divisions, but are now named squadrons, and the person who commanded them, exerted all their skill and genius to gain advantages over their enemies, by opportunely getting to windward, by seizing the favourable occurrence of the tide, or by manoeuvring in advantageous situations.

At the battle of Actium, Augustus, finding himself inferior to Mark Anthony in the number of his ships, had the sagacity to draw up his line of battle along the entrance of the gulf of Ambrac, and thereby to make up for his deficiency. This naval manoeuvre, as well as that of getting a windward of the enemy, in order to bear down upon him with more certainty and effect, exists to the present day.

We act precisely upon the same principles in both cases, by which the ancients were governed; with the additional advantage, in fighting to windward, of covering the enemy's line with smoke from the discharge of ordnance and fire-arms. The French call this being in possession of the closed line.

In those times, ships were boarded much sooner than they are at present. Most engagements at sea are now determined by cannon-shot. Among the ancients, when two ships endeavoured to board each other, the rowers drew from the oars, to prevent them from being broken in the shock.

The manoeuvre which was practised on this occasion, was for the ship that got to windward of its adversary, to run upon its side, with the prow; which being armed with a long sharp piece of iron, made so deep an impression in it, that the ship thus attacked, generally sunk. The voyages which were afterwards made on the ocean, rendered it necessary that this armament be more still, and were double-decked; and since the invention of gunpowder, tiers of guns have been substituted in the room of rows of oars.

On the decline and fall of the Roman empire, the Saracens got the ascendency in naval tactics. They took advantage of this superiority, and extended their conquests on all sides. The tract belonging to the Mediterranean, together with the adjacent islands, fell under their dominion. Mankind are indebted to them for considerable improvements in naval tactics.

It was only under Charlemagne, that the Europeans can be said to have paid any great attention to their navy. That monarch kept up a regular intercourse with the caliphs of the East; and having just grounds to apprehend an invasion from the Normans, he constructed vessels for the defence of his coasts.

During the reign of the first French kings belonging to the third race, naval tactics were little attended to, on account of the small extent of maritime coast which France possessed at that period. It was only in the days of Louis the Younger, and of Louis surmised the Saint, that we discover any traces of a considerable fleet, especially during the crusades.

Under Charles the Fifth, and his successor Charles the Sixth, the French got possession of several sea-ports, and had command of a long line of coast. Yet neither they nor the English, with whom they were frequently at war, had at that period any thing like the fleets which are now fitted out.

The discovery of America by Columbus, and the more lucrative possession of the East Indies, induced the principal courts of Europe to increase their naval establishments, for the purpose of settling colonies, and of bringing home, without the danger of molestation or piracy, the wealth and produce of the eastern and western worlds.

The French marine was far from being contemptible under Francis the First; but it grew into considerable reputation during the administration of cardinal Richelieu, in the reign of Louis the Thirteenth; and continued to increase until the reign of Louis, which was so gloriously won by the English, under William the Third. From that epoch it began to decline; while the English, on the other hand, not only kept up the reputation of their armed forces, but added to their pre-eminency, which was their predecessors, but rendered themselves so thoroughly skilled in naval tactics, that they have remained masters of the sea to this day. See War, art of.

TEN, in zoology, a genus of animals belonging to the class of vernix, and order of intestina. The body is long, depressed, and jointed like a chain, and contains a mouth and visceria in each joint. According to the number of their joints, there are ninety-two species; all which inhabit the intestines of various animals, particularly of quadrupeds.

Seven species of Tenia are peculiar to man: 1. Accommodating, which is found in various parts of the body, is broad, and has bursae in the hinder part; inhabits the liver, the placenta uterina, and the sac which contains the suprarenal fluid of human persons. 2. Cellulosa, which is included in the carotegua, and the cellular substance of the muscles; is about an inch long, half an inch broad, and one-fourth of an inch thick, and is very tenacious of life. 3. The dentata, has a pointed head; the large joints are streaked transversely, and the small joints are all dilated; the oscaum or opening in the middle of both margins is somewhat raised. It is narrow, ten or twelve for long, and broad for long, and its ovaria are not visible to the naked eye; and the head underneath resembles a heart in shape. It inhabits the intestines. 4. The licea, is white, with joints very small and deciduous; the ova, which is solitary. It is from eighteen to one hundred and twenty feet long; its joints are streaked transversely; its ovaria are disposed like the petals of a rose. 5. The vulgaris, has two lateral mouths in each joint; it attaches itself so firmly to the intestines, that it can scarcely be removed by the most violent medicines; it is slender, and has the appearance of being membraneous; it is somewhat peculiar, from ten to sixteen feet long, and about four lines and a half broad at one end. 6. The lutea, which chiefly inhabits the liver of the trout, but is also to be found in the intestines of the human species. 7. The solium, has a marginal mouth, and is commonly found in the ovilia, found in the liver and omentum of sheep. See Plate Nat. Hist. fig. 389.

The structure and physiology of the tenia are curious, and it may be amusing as well as instructive to consider it as a single animal designed to feed upon such juices of animals as are already animalized; and is therefore most commonly found in the alimentary canal, and in the upper part, where there is the greatest alimentation with the natural food of the tenia. As it is thus supported by food which is already digested, it is destitute of the complicated organs of digestion. As the tenia solium is most frequent in this country, it may be proper to describe it more particularly.

It is from three to thirty feet long, some sixty feet. It is composed of a head in which are a mouth adapted to drink up fluids, and a pair of jaws for seizing the head a fixed situation. The body is composed of a great number of distinct pieces articulated together, each joint having an organ by which it attaches itself to the neighbouring part of the body, and thus, in a manner, the head are always small, and they become gradually enlarged as they are farther removed from it; but towards the tail a few of the last joints again become diminished in size. The extremity of the body is terminated by a small semicircular joint, which has no opening in it.

The head of this animal is composed of the same kind of materials as the other parts of its body; it has a rounded extremity, which is considered to be its mouth. This opening is continued by a short duct into two canals; these canals pass round every joint of the animal's body, and convey the aliment. Surrounding the opening of the mouth are a number of projecting radii, which are of a fibrous texture, whose direction is longitudinal. These radii appear to serve the purpose of tentacula for fixing the orifice of the mouth, and muscles expand the cavities of the mouth, from their being inserted along the brim of that opening. After the rounded extremity, or head, has been narrowed into the neck, the lower part becomes flattened, and has two small tubercles placed upon each fluted.
side; the tubercles are concave in the middle, and appear destined to serve the purpose of suckers for attaching the head more effectually. The internal structure of the joints composing the head is partly vascular and partly cellular; the substance itself is white, and somewhat resembles in its texture the coagulated lymph of the human brain.

The alimentary canal passes along each side of the animal, forming a cross or four drops, or a part of the animal's body which they inhabit, various remedies are advised for removing them; many of which are ineffectual, and others very injurious by the violence of their operation. Drastic purges seem to operate upon tanta, partly by irritating the external surface of their bodies, so as to make them quit their holds, and partly by the violent contractions produced in the intestine, which may sometimes divide the bodies of tanta, and even kill them by bruising. The most effectual remedy, however, has been found to be the digitalis in substance.

TAGEÊS, French marigold, a genus of plants of the lupin and order of polygonia superlum; and in the natural system ranging under the 40th order, composita. The receptacle is naked; the pappus consists of five erect awns or beards; the calyx is monophyllous and achene, and tubular; and there are four persistent florets of the ray. There are three species, the palata, erecta, and minuta; of which the two first have been cultivated in the British garden, at about 936, for it is mentioned in Gerard's Herball, which was published that year. They are both natives of Mexico.

The erecta, or African marigold, has a stem subdividing and spreading, and has formed itself into a great many varieties: 1. Pale yellow, or brim-stone colour, with single, double, and fistulous flowers. 2. Deep yellow, with single, double, and fistulous flowers. 3. Orange-coloured, with single, double, and fistulous flowers. 4. Middling African, with orange-coloured flowers. 5. Sweet-scented African. These are all very subject to vary; so that unless the seeds are very carefully gathered from the finest flowers, they are apt to degenerate; nor should the same seeds be too long sown in the same garden, for the same reason; therefore those who are desirous to have these flowers in perfection, should exchange their seeds with some person of integrity at a distance, where the soil is of a different nature, at least every other year. If this is done, the varieties may be continued in perfection.

TALT, or EASTERN TALT, are either general or special. Talt general, is where lands and tenements are given to one and the heirs of his body begotten, which is called talt general; because, how often soever such done may be married, his heirs, by every such marriage, are capable of inheriting the estate talt. Tenant in talt special, is where the gift is restrained to certain heirs of the grantee, and not to all in general, which may happen in several ways. Estates talt are likewise diversified by the distinction of male and female, as if lands are given to a man and the heirs male of his body begotten; this is an estate in talt, male special; but if to a man and the heirs female of the body of his present wife begotten, this is an estate in talt, female special. So in case of a gift in talt male, the female line shall not inherit; and so converso.

As the word heirs is necessary to create a fee, so the word body or some other words of inheritance necessary to make a fee talt, and ascertain to what heirs the estate is limited. Therefore, if the words of inheritance or procreation are omitted, although the others are inserted, this will not make an estate talt. As if an estate is granted to a man and the issue of his body, this is only an estate for life, the words of inheritance being wanting; and a grant to a man, and his heirs male or female, is an estate in fee simple, not in fee talt, as there are no words to ascertain the body from whence they shall issue.

Though in wills, where greater latitude is given, an estate talt may be devised by the words, to a man and his heirs male, or other irregular modes of expression. The incidents to a tenancy in talt are principally these: 1. A tenant in talt may commit waste on an estate without being imprisoned for the same. That the wife shall have her dower of the estate talt. 3. That the husband of a female tenant in talt may be tenant by courtesy. 4. An estate talt may be barred or destroyed by fine, a recovery, or a legal warranty, descending with assets to the heir.

And by stat. 26 Hen. VIII. c. 13. all estates talt (in common with all estates of inheritance) are forfeited to the king on conviction of high treason. By stat. 32 Hen. VIII. c. 29, certain leases which do not tend to prejudice of the heir are allowed to bind the issue in talt. A stat. of the same year, c. 36, declares a fine duly levied by a tenant in talt to be a complete bar to all persons claiming under such entail.

And lastly, by 33 Hen. VIII. c. 39, all estates talt are liable to be charged for debts to the king by record or special contract. This is the reason why they may not be sold for the debts contracted by a bankrupt; and by the construction put on stat. 43 Eliz. c. 4, an appointment by tenant in talt, of the lands entailed to a charitable use, is good without limitation.

TALT, in the Turkish customs, (boshaws of three talls, sc.) See TUG.

TALC. Though this term has often been a synonym of mica in mineralogy, it is adopted by the moderns, to denote a stony substance which differs from it, especially in an uncertainty sensible to the touch, and in the vitreous electricity which it communicates to sealing-wax by friction, whilst mica gives it the reflection necessary to make the four varieties of this stone; precisely, the laminary tale, or Venice tale; the foliated tale, or chalk of Brimmon; compact tale, as the hard stone; these three first give the positive or vitreous electricity to sealing-wax. The fourth variety, or the steatite tale, communicates the negative or resinous electricity to it by friction.

The characters of this stone are, a specific gravity 2.5834 and 2.9902; a texture easy to be split into sheets; a soft and unctuous surface; the primitive form of a right rhomboidal prism, its bases having angles of 120 degrees and 60 degrees, and in which sections parallel with these bases are
1. Talpa Europaea, the common mole. The whole form of the mole is eminently calculated by nature for its obscure and subterranean life. The body is fusiform, cylindrical; the snout slender but very strong and tenacious; the head not distinguished from the body by any appearance of neck; the legs so extremely short as scarcely to project perceptibly from the body; the skin is smooth and tougher in proportion than in other quadrupeds, and the fur with which it is covered equally surpasses that of other animals in fineness and softness. The muscular strength of the mole is very great, and it is enabled to force itself into the ground with an extraordinary degree of celerity. The general length of the mole is about five inches and three quarters, exclusive of the tail, which measures one inch. This animal supposed to possess the power of hearing in an exquisite degree; and if at any time it emerges from its subterranean retreat, instantly disappears on the approach of any danger. When first taken, either by digging it out or by slaughter, it is silent, and prepares for defence by exerting the strength of its claws and teeth. According to the count de Buffon, so lively and recalcitrant an attachment subsists between the mole and its young, that they seem to dread of discharging all other society.

The mole is furnished with eyes so extremely small that it has been doubted whether they were intended by nature for distinct vision, or rather for conveying the image of the creature to a degree of notice of the approach of light as might sufficiently warn it of the danger of exposure. Galen, however, seems to have been of a different opinion, since he ventures to affirm that the eyes of the mole are furnished with the crystalline and vitreous humours, encompassed with their respective tunic ; so accurate an anatomist was that great man, even unassisted by glasses.

The mole is reported to feed not only on worms, insects, &c. but also on the roots of vegetables; but it is certainly more carnivorous than fungivorous. It is even a very fierce and voracious animal in particular circumstances; and as thus far observed, by sir Thomas Brown, that whatever these animals are contented with under ground, yet, when above it, they will sometimes tear and cut one another; and in a large glass case, wherein a mole, a toad, a rat, and a dead frog, were inclosed, we have known (says he) the mole to dispatch them, and to devour a good part of them both.

The mole is with difficulty kept alive in a state of confinement, unless constantly supplied with a provision of damp mould to reside in.

Like other animals of a black colour, the mole is sometimes found perfectly white, or cream-coloured, and sometimes spotted. In a memoir relative to the mole, published by M. de la Flaffe, it appears that four varieties may be reckoned, viz. the white mole, the rufous or tawny mole, the greenish-yellow or citron-coloured mole (found in some parts of France), and, lastly, the spotted mole, which is variegated either with white or tawny spots or patches. The mole brings four or five young.

The greatest misfortune that befalls the mole is, the sudden overflowing of rivers, when they are said to be seen swimming in great numbers, and using every effort to obtain a more elevated situation; but a great many of them perish by this occasion, as well as the young, which remain in their holes.

Linnaeus, in the twelfth edition of the Systema Naturae, affirms that the mole produces the greatest number of young of any single species, and that the same observation is repeated in the Gmelinian edition of that work. This, however, is flatly contradicted by the count de Buffon, who observes, that the mole sleeps so little during winter, that it raises the earth in the same manner as in summer; and that the country people remark that the thaw approaches, because the moles make their holes. They endeavour to get into warm grounds, gardens, &c. during this season more than at others.

This animal is said to be unknown in Ireland, and Siberia it arrives at a larger size than in Europe. The fur is so soft and beautiful, that it would make the most elegant fur cloth, which is not the difficulty a curtain and dressing the skin deter from experiments of this nature.

2. Talpa radiata, radiated mole. This is somewhat smaller than the common mole, and is of a dusky or blackish colour. In general form it resembles the preceding species, being of broad fore legs with long claws; the hind legs scaly and with much weaker claws; the nose long, and bent at the end; with a circular series of radiated tetrads; the length from nose to tail, about three inches and three quarters. It is an inhabitant of North America, forming subterraneous passages, in different directions, in uncultivated fields, and is said to feed on roots. This species is the borex cristatus of Linnaeus; being placed in that genus on account of its teeth, in despite of its appearance. It is, perhaps, in reality, no other than a variety of the former species, or a sexual difference.

TAMARINDUS, the tamarind-tree, a genus of plants arranged by Linnaeus under the class of triandria, did not occur in monogynia; but Woodville, Schreber, and other late botanists, have found that it belongs to the class of monadelphia, and order of triandria. In the natural system it is maintained by Mr. Tournefort. There is only one species, the Indica, which is a native of both Indies, of America, of Arabia, and of Egypt, and was cultivated in Britain before the year 1633.

The tamarind-tree rises to the height of thirty or forty feet, sending off numerous large branches, which stand to a considerable extent, and have a beautiful appearance; the trunk is erect, and covered with rough bark, of a greyish or ash-colour; the leaves are small and pinnaed, and of a greenish yellow colour; the flowers grow on such an extensive kind, and grow in lateral clusters; the calyx consists of four leaves, and the corolla of three petals, which are of a yellowish hue, and are beautifully diversified with red veins. The fruit is a pod of a roundish compressed form, from three to five inches long, containing two, three, or four seeds, lodged, in a dark pulpy matter. The tamarind is easily raised with us from the stones even of the preserved fruit, and is a beautiful stone-plant, rising to the height of four or five feet.

The pulp of the tamarind, with the seeds,
The fruit, of which the use of was first learned the Arabs, contains a larger proportion of acid, with the saccharine matter, than is usually found in the fructus acido-dulces, and is therefore not only employed as a laxative, but also for abating thirst and heat in various climatic complaints, and for correcting putrid disorders, especially those of a bilious kind; in which the cathartic, antiseptic, and refrigerant qualities of the fruit have been found equally useful. When intended merely as a laxative, it may be of advantage to join it with muum, or purgatives of a sweet kind, by which its use is rendered more effectual. Three drachms of the pulp are usually sufficient to open the body; but to prove moderately cathartic, one or two ounces are required. It is an ingredient in electuarium e casisi, and electuarium e semo or lenticulare.

TAMARIX, the tamarisks, a genus of plants in the class of pentandria, and order of trixioid, and in the natural system ranging under the order of the Diottyceae. The calyx is quinquepartite; the petals are five; the capsule is unilocular and trivalvular, and the seeds pappose. There are 4 species.

The bark and leaves of the tamarisk-tree are moderately astringent, but never prescribed in the present practice.

TAMBOUR, in fortification, is a kind of work formed of palisades, or pieces of wood, ten feet long and six inches thick, planted close together, and driven two or three feet into the ground; so that when finished it may have the appearance of a wooden rampart. Loop-holes are made six feet from the ground, and three feet above, about eight inches long, two inches wide, and six inches between. Behind is a scaffold five feet wide, on which the soldiers stand upon. They are frequently made in the form of arms, mounted on the arms of the covert-way, at the salient angles, in the grooves, half-moons, and ravelins, &c.

TAN, in fortification, are also solid pieces of earth which are made in that part of the covert way that is joined to the parapet, and lies close to the traversies, being only three feet distant from them. They serve to prevent the covert way from being embanked, and obstruct the enemy's view towards the traversies. In the construction of the covert way, they answer the same purposes that works on crenellau would.

Tambour likewise means in fortification, a single or isolated traverse, which serves to close up that part of the covert way where communication might have been made in the plaza for the purpose of going to some detached work.

It also signifies, both in French and English, a little box of timber-work coverd with a clieling, within the porch of certain churches, both to prevent the view of persons passing by, and to keep off the wind, &c. by means of folding-doors. In many instances it is the same as archch.

TAMUS, black, brown, a genus of plants of the class of diccia, and order of hexandra, and in the natural system ranging under the 11th order, sarmentaceae. The male and female flowers are both separet; there is no corolla; the flower is 6-locular, and consists of three sepals, three petals, and three stamens; it is dioecia, and contains two seeds. There are only two species. The communis, or common black broony, is a native of England. It has a large root, which sends forth several long slender stems; the leaves are large, heart-shaped, dark green, and grow on long footstalks; the flowers are greenish, and the berry red. It flowers from May to August, and is frequent in hedges.

TAN, the bark of the oak, chopped and ground in a tannin-mill into a coarse powder, to be used in the tanning of leather.

Deyouex was, perhaps, the first chemist who ascertained the peculiar nature of tan, or tanning. He pointed out in his analysis of nutgalls, as a peculiar resinous substance, but without assigning it any name. Seguin soon after engaged in a set of experiments on the art of tanning leather; during which he discovered that tan has the property of precipitating glue from its solutions in water, and of combining with the skins of animals. This led him to suppose it the essential constituent of the liquids employed for the purpose of tanning leather, the main tanning and tanning principle given it by the French chemists. But it is to Mr. Proust that we are indebted for the investigation of the nature and properties of tan, and of the methods of obtaining it in a separate state. Much curious and important information has likewise been obtained by the experiments of Mr. Davy on the constituent parts of astringent vegetables, and on their operation in tanning.

Tan exists in a great number of vegetable substances; but it may be procured most readily and in the greatest purity from nutgalls and catechu.

Nutgalls are excrences formed on the leaves and bark of the puncture of an insect which deposits its eggs on them. The best are known by the name of Aleppo galls, shipped in large quantities in this country for the use of the dyers, calico-printers, &c. and when exposed to the air, they are oxidized on the surface, of an olive-green colour, and an excessively disagreeable taste. They are in a great measure soluble in water; what remains behind is tasteless, and possesses the properties of the fibre of wood. A very great proportion of the water is necessary to carry off everything soluble. Deyouex found that a French pound of nutgalls required 96 French pints of water, applied in 20 different portions one after the other, and allowed to remain in a considerable time. This, reduced to our standard, gives us about 150 English pints to a pound troy of nutgalls.

From the analyses of Deyouex and Davy, it follows that the soluble part of nutgalls consists chiefly of five substances, namely, tan, extract, mucilage, gallic acid, and gallat of lime. Mr. Davy found that 500 grains of Aleppo galls formed with water a solution which yielded by slow evaporation 185 grains of matter. This he found composed of

- 130 tan
- 31 gallic acid and extract
- 12 mucilage and extract
- 12 lime and saline matter

183.

So that the tan constitutes rather more than two-thirds of the whole.

According to Mr. Davy, the strongest infusion of galls is of the specific gravity 1.069; and when evaporated at a temperature below 200° yields a mass composed of 95 per cent. of gallic acid and extract. But at a boiling heat most of the gallic acid is dissipated or destroyed, and a portion of the extract is rendered insoluble in water.

Catechu, or terra japonica as it is also called, is a substance obtained by decoction and evaporation from a species of the nitmous which abounds in India. It has a reddish brown colour, and an astringent taste, leaving an impression of sweetness; it is not altered by exposure to the air. There are two varieties of it; one from Bombay, which has the lightest colour, and a specific gravity of 1.39; and one from Bengal, which is the colour of chocolate; its specific gravity is 1.28. This substance was examined by Deyouex, and found to consist chiefly of tan, combined with a peculiar species of extract.

Tan obtained from the infusion of nutgalls is a brittle substance, of a brown colour. It breaks with a vitreous fracture, and does not distil moisture with it. Its taste is exceedingly astringent. It is very soluble in water. The solution is of a deep-brown colour, a very astringent and bitter taste; and has the colour which distinguishes a solution of nutgalls. If fruits, when agitated, like a solution of soap, but does not feel mucinous. Tan is still more soluble in alcohol than in water. The solution has a deep-brown colour and an astringent taste.

When heated, it blackens, emits carbonic acid gas, and in the open air bursts, leaving a smell of burnt lime.

From the experiments of Proust, Davy, and Deyouex, we learn that it is capable of combining with oxygen; but at the same time it is either decomposed altogether, or its nature, completely altered. Thus nitric acid, when thrown into a yellowish-brown matter soluble in alcohol, and similar in its properties to an extract. Oxymuriac acid produces similar effects; and Mr. Prae has observed, that
the peroxide of tin changes it also into an extract, perhaps by communicating oxygen.

The action of the metals upon tan does not seem to be great; but almost all the metallic oxides have an affinity for it, and are capable of combining with it to form nearly insoluble in water. Hence the reason why the infusion of nutgalls precipitates metallic solutions so readily. These compounds have been hitherto in a great measure overlooked by chemists. The following observations contain the facts at present known.

When the peroxide of tin or zinc is boiled in the infusion of galls, it acquires a dull yellow colour, and abstracts all the constituents from the infusion, leaving behind only pure water. The oxides thus combined with tan, &c. are partly soluble in nauritic acid, and the solution indicates the presence of tan and gallic acid. When the peroxide of tin is allowed to act upon the cold infusion, it abstracts all in a few days. Whose Mr. Pronst affirms, that in that case the gallic acid is mostly destroyed, and a portion of the tan brought to the state of extract.

When the metallic salts are mixed with the infusion of galls, the precipitate is formed, combined with the tan, the extract, and the acid of the infusion; and, according to Davy, it contains also a portion of the acid of the metallic salt.

Tan produces no change upon the solution of sulphur of iron; but when it is mixed with a solution of the oxysulphate of iron, a deep blue coloured precipitate immediately appears, consisting of the tan combined with the oxide. This precipitate, when dried, assumes a black colour. It is decomposed by acids.

When too great a proportion of oxysulphate of iron is poured into a solution of tan, the sulphuric acid, set at liberty by the combination of the iron and tan, is sufficient to redissolve the precipitate as it appears; but the precipitate obtained in this way, contains, through saturating this excess of acid with potass. When the experiment is performed in this manner, all the oxysulphate of iron which remains in the solution is undecomposed. Care must be taken not to add an excess of the solution to the liquid from which the tan is to be separated; because the compound of tan and gelatine is re-dissolved by the solution of gelatine. According to the analysis of Mr. Davy, this compound, when dried in the temperature of 150°, is composed of 54 gelsine 46 tan 100.

It appears, from the experiments of Mr. Davy and Mr. Chenevix, that tan is sometimes formed in vegetables by the action of heat. Thus no tan can be detected in the decoction of coffee-beans, unless they have been roasted; but in that case their decoction precipitates gelatine.

From the experiments of Mr. Davy, we infer that most of the different classes of bodies capable of combining with tan are nearly in the following order:

Earth, Acid, Alkalies, Neutral salts, Gelatine,

But the order of the individual substances belonging to each of these classes remains still to be ascertained.

Tan affects particularly the bark of trees: but it also exists in the sap and in the wood of a considerable number, and even in the leaves of many. It is very seldom that it exudes spontaneously; yet this seems to be the case with a variety of kio.

It has been ascertained by Mr. Biggin, that when the barks of trees are examined at different seasons, they vary in the quantity of tan. The quantity varies also with the age and size of the tree. The greatest proportion of tan is contained in the inner barks. The epidermis usually contains none.

The following table exhibits the proportion of solid matter extracted by water from different vegetable substances, and the quantity of tan contained in that solid matter, as ascertained by the experiments of Mr. Davy.

TANACETUM, tansy, a genus of plants of the class of synagenesia, and order of polygamous, and in the natural system ranging under the 40th order, composite. The receptacle is naked; the pappus somewhat emarginated; the calyx imbricated and hemispherical; the flrets of the radius are tri-lobed, and scarcely dis-tinguishable. There are nine species; of which one only is a native of Britain, the vulgar, or common tansy. Of this species there is a variety with curled leaves, which is therefore called curled tansy. The tansy has a bitter taste, and an aromatic smell, disagreeable to many people. It is esteemed good for warming and strengthening the stomach; for which reason the young leaves have obtained a place among the culinary herbs, their juice being an ingredient in puddings, &c. It is rarely used in medicine, though extolled as a good emmenagogue. A drachm of the dried flowers has been found very beneficial in hysterical disorders arising from suppression. The seeds and leaves were formerly in considerable esteem for destroying worms in children, and are reckoned good in cholics and flatulencies.

TANACETUM, a genus of the angiosperma order, in the didynamia class of plants, and in the natural method ranging under the 45th order, putaminae. The calyx is monophylous, tubulate, truncate, and entire; the corolla long, monopetalous, and white; the tube cylindrical; the lymi erect, spreading, and nearly equal; the nut a berry, covered with a thick, large, oblong, internally divided into two parts; in the pulp are contained a number of seeds. There are only two species of this genus, the juroba and pahastaticum, both natives of Jamaica. They grow by the sides of rivers, and climb on trees and bushes.

TANAGRA, tanger, in ornithology, a genus of birds belonging to the order of passerises. The beak is conical, acuminate, emarginated, almost triangular at the base, and inclining a little towards the point. Dr. Latham has described 44 species, all of which are of foreign extraction. See Plate Nat. Hist. f. 398.
Tangent, in geometry, is defined, in general, to be a right line which touches any arc of a curve, in such a manner that no right line can be drawn between the tangent and the arc. See Plate Miscd. fig. 229.

The tangent of an arc is a right line drawn perpendicular to the arc at the end of a diameter, passing to one extremity of the arc, and terminated by a right line drawn from the centre through the other end of the arc, and called the secant.

The tangent of a curve is a right line which only touches the curve in one point, but does not cut it.

In order to illustrate the method of drawing tangents to curves, let AGC (fig. 227) be a curve of any kind, and C the given point from where the tangent is to be drawn. Then conceive a right line, $mC$, to be carried along uniformly, parallel to itself, from A towards Q; and let, at the same time, a point $p$ so move in that line, as to describe the given curve AGC; also let $mM$, or $Cp$, express the fluxion of $AM$, or the velocity wherewith the line $mc$ is carried; and let $sc$ express the corresponding fluxion of $CM$, or the velocity of the point $p$, in the line $mp$: moreover, through the point $C$ let the right line SF be drawn, meeting the axis of the curve, AQ, in F.

Now it is evident, if the motion of $p$, along the given curve, be supposed to be the same equitable at C, the point $p$ would be at S, when the line itself had got into the position $sc$; because, by the hypothesis, $Cm$ and $sc$ express the distances that must be described by the two uniform motion in the same time. And if $sc$ is assumed to represent any other position of that line, and the contemporary position of the point $p$, it will have an equipollent velocity of the same distance $Ce$, and $es$, gone over in the same time by the two motions, will always be to each other as the velocities, or as $Ce$ to $as$. Therefore, since $Cm = sc$, $C = as$ (which is a known property of similar triangles), the point $p$ will always fall in the right line $FC$ fig. 228; whence it appears, that if the motion of the point $p$ along the line $mc$ was to become uniform at C, that point would then move in the right line CS, instead of the curve-line CG. Now, seeing the motion of $p$, in the description of curves, must either be an accelerated or retarded one: let it be first considered as an accelerated one, in which case the arc CG will fall wholly above the line $FC$; but, because the distance of the point $p$ from the axis AQ, at the end of any given time, is greater than it would be if the acceleration was to cease at C; and if the acceleration is continued, it will be always found in the said right line $FS$. But if the motion of the point $p$ is a retarded one, it will appear, by argument in the same manner, that the arc CG will fall wholly below the right line CD, as in fig. 229.

This being the case, let the line $mg$, and the point $p$, along that line, be now supposed to move back again, towards A and $m$, in the same manner they proceeded from thence; then, since the velocity of $p$ did before increase, it must now, on the contrary, decrease; and therefore a point, at the end of a given time, after re-passing the point C, is not so near to AQ, as it would have been had the velocity continued the same as at C, the arc $Ch$ (as well as $CG$) must fall wholly above the right line $FC$, and the point $p$ would be $as$ instead of $es$ (which is a known property of similar triangles). The point $p$ will always fall in the right line $FS$ as before. But if the motion of the point $p$ is a retarded one, it will appear, by argument in the same manner, that the arc $Cg$ will fall wholly below the right line $CD$, as in fig. 229.

In a preceding article (Tan), it was stated that gelatine with tannin, or the tanning principle of vegetables, formed a combination which is insoluble in water. Upon this depends the art of making leather; the gelatinous part of the skin combining with the tannin of the bark, forms that leather.

The process which has long been used in this country is as follows: The leather tanned in England consists chiefly of three sorts, known by the names of butts or backs, hides, and skins. Butts are generally made from the stoutest and heaviest ox-hides, and are generally made from the stoutest and heaviest ox-hides, and are managed as follows: after the horns are taken off, the hides are laid smooth in heaps for one or two days in the summer, and for five or six in the winter; they are then hung on poles in a close room called a smoke-house, in which is kept a smouldering fire of wood; this occasions a small degree of purification, by which means the hair is easily got off, by spreading the hide on a sort of wooden horse or beam, and scraping it with a crooked knife. The hair being taken off, the hide is thrown into a pit or pool of water, to cleanse it from the dirt, &c., which being done, the hide is again spread on the wooden beam, and the grease, loose or extra-fat, &c., carefully scrubbed out or taken off; the hides are then put into a pit of strong liquor, called ooze, prepared in pits kept for the purpose, by infusing ground bark in water; this is termed colouring; after which they are removed into another pit, called a scouring, which consists of water strongly impregnated with vitriolic acid, or with a vegetable acid prepared from rye or barley. This operation (which is called raising), by drawing out the fluid of the hides, occasions them more readily to imbibe the oozc, the effect of which is to combine with the gelatinous part of the skin, and form with it leather. The hides are then taken out of the scouring, and sprinkled with water, filled a bander, with a quantity of ground bark strewn between each. After lying a month or six weeks, they are taken up; and the decayed bark and liquor being drawn off out of the pit, it is filled again with strong oozc, when they are put in as before, with bark between each hide. They now lie two or three months, at the expiration of which the same operation is repeated; and they remain four or five months, when they again undergo the same process, and after being three months in the last pit, are completely tanned; unless the hides are so remarkably stout as to want an additional pit or layer. The whole process requires ten or twelve months, and sometimes two years, according to the substance of the hide, and discretion of the tanner.

When taken out of the pit to be dried, they are hung on poles; and after being compressed by a steel pin, and beaten together by wooden hammers, called battes, the operation is complete; and when thoroughly dry, they are fit for sale. Butts are chiefly used for the soles of stout shoes.

The leather which under the denomination of hides, is generally made of cow hides, or the lighter ox-hides, which are thus managed: After the horns are taken off, and the hides washed, they are put into a pit of water, saturated with lime; where they remain a few days, when they are taken out, and the hair scraped off on a wooden beam, as before described; they are then washed in a pit or pool of water, and the loose flesh, &c., taken off, and the hides are then shifted into a pit of weak oozc, where they are taken up, and put down (which is technically termed handling) two or three times a day, for the first week; every second or third day they are shifted into a pit of fresh oozc, somewhat stronger than the former, till the end of a month or six weeks they are put into a strong oozc, in which they are handled once or twice a week with fresh bark for two or three months. They are then removed into another pit, called a layer, in which they are laid smooth, with bark ground very fine, strewn between each hide. After removing here two or three months, they are generally taken up, when the oozc is drawn out, and the hides put into a pit with fresh oozc and fresh bark, where, after lying two or three months more, they are completely tanned; except a very few stout hides, which may require an extra layer; they are then taken out, and hung on poles, and being hammered and smoothed by a steel pin, are then dry, fit for sale. These hides are called crop hides; they are from ten to eighteen months in tanning, and are used for the soles of shoes.

Skins is the general term for the skins of calves, seals, hogs, dogs, &c. These, after being washed in water, are put into lime-pits, as before mentioned, where they are taken.
The resemblance between the oxides of tantalum and columbium is striking. The only property in which they differ is the insolubility of the first in acids; but we know not what acids Ekeberg tried, and Mr. Hatton's "full solution of columbium in nitric acid.

Tantalus, or irlenis, a genus of birds of the order Grallae. The generic character is bill long, subulate, rufous ascended; face naked; nostrils oval; feet four-toed, palmar opposite. This is a rare species. The most remarkable are:

1. The loculator, or wood ibis: (1) face bluish; bill reddish; legs, quill and tail feathers, black; body white. (2) Head and neck white, varied with yellow; body black; belly crimson. (3) Wing feathers white, with a black blotch in the middle. Inhabit New Holland, and the warmer parts of America. It is three feet long; is very slow in flight, and stupid; sits on trees, and feeds on herbs, seeds, fruits, fish, and reptiles. The flesh is very much esteemed.

2. The leucophaeus, or white-headed ibis, inhabits India; and every year before the rainy season sets in, it sheds its rosy feathers.

3. The ibis, or Egyptian ibis, inhabits in vast numbers the lower part of Egypt, and is held sacred by the inhabitants; it is clearing the land of reptiles and insects, which are left after the inundation of the Nile. It rests in an erect posture, and is said to destroy the young of the crocodile.

4. The melanocephalus, or black-headed ibis, is a very beautiful bird that inhabits India. See Puste Nat. Hist. f. 391.

Tantalus's Cup. See Hydraulics.

Tapestry. See Tendrillae.
groove from one end to the other, capable of containing a long round piece of wood, fastened therein with hooks. The use of it is to tie the ends of the warp to. The warp, which may be from one or two inches thick, is wound on the upper roller; and the work, as fast as woven, is wound on the lower. Withinside the planks, which are seven or eight feet high, 14 or 15 inches broad, and three or four thick, are holes pierced from top to bottom, in which are put thick pieces of iron, with hooks at each end, serving to sustain the cost-stave: these pieces of iron have also holes pierced, by putting a pin in which, the stake is drawn nearer or set further off; and thus the costs or threads are stretched or loosened at pleasure. The cost-stave is about three inches diameter, and runs all the length of the loom; on this are fixed the costs or threads, which make the threads of the warp cross each other. It has much the same effect here, as the spring-stave and threadles have in the common looms. The costs are little threads fastened both ends of the warp, in a kind of sliding knot, which forms a sort of mesh or ring. They serve to keep the warp open for the passage of brocades woven with silks, woollens, or other matters used in the piece of tapestry. The last piece, or threads, are a number of little sticks of different lengths, but all about an inch in diameter, which the workman keeps by him in baskets, to serve to make the threads of the warp cross each other, by passing each cross thread through these, and crowed may retain their proper situation, a packthread is run among the threads, above the stick.

The loom being thus formed, and mounted with its warp, the first thing the workman does, is to draw on the threads of this warp, the principal lines and strokes of the design to be represented on the piece of tapestry; which is done by applying cartons, made from the painting he intends to copy, to the side that is to be the wrong side of the piece and back, with a blacklead pencil, following and tracing out the contours thereof on the thread of the right side, so that the strokes appear equally both before and behind.

As for the original design the work is to be finished by, it is hung up behind the workman, and wound on a long staff, from which a piece is unwound from time to time as the work proceeds.

Besides the loom, &c. here described, there are three other principal instruments required for working the silk or the wool of the wood within the threads of the warp; these are a broach, a reed, and an iron needle.

The broach is made of a hard wood, seven or eight inches long, and two-thirds of an inch thick, ending in a point with a little handle. This serves as a shuttle; the silks, woollens, or cottons, which are to be used in the work, being wound on it.

The reed or comb is also of wood, eight or nine inches long, and an inch thick on the back, whence it grows less and less to the extremities of the teeth, which are more or less apart, according to the greater or less degree of fineness of the intended work. Lastly, the needle is made in form of the common needle, only larger and longer. Its use is to press close the silks when there is any line or colour that does not fit well.

All things being prepared for the work, and the workman ready to begin, he places himself on the wrong side of the piece, with his back towards the design; so that he works on what he does, and being obliged to quit his post, and go to the other side of the loom, whenever he would view and examine the piece, to correct it with his pressing-needle. To put silk, &c. in the warp, he has to turn and looks at the design; then, taking a broachful of the proper colour, he places it among the threads of the warp, which he brings cross each other with his fingers, by means of the costs or threads fastened to the staff; then, as he repeats every time he is to change his colour, having placed the silk or wool, he beats it with his reed or comb; and when he has thus wrought in several rows over each other, he goes to see the effects they have in order to reform the contours with his needle, if there should be occasion. As the work advances, it is rolled upon the lower beam, and they urrel as much warp from the upper beam above to the lower, as is the like they do of the design behind them.

When the pieces are wide, several workmen may be employed at once.

We have two things to add: the first is, that the thread does go on much more slowly than the low-warp, and takes up almost twice the time and trouble. The second is, that all the difference that the eye can perceive between the two kinds, consists in this: the warp there is wound to a new fillet, about one-twelfth of an inch broad, running on each side from top to bottom, which is wanting in the high warp.

But, for the satisfaction of our readers, we shall here describe the principal parts of the loom for the manufacture of tapestry of the high warp, or that in a situation perpendicular to the horizon. The loom consists,

1. Of two strong upright posts fixed in the floor; these support (2) two rollers, of which the upper end holds the chain, the lower holds the tapestry, which is rolled upon it according as the work goes forward: the threads are fastened at their ends to a sheet, or thick rod, which is lodged in an iron groove in the lower roller.

2. The two tauters, one called the great tauter, for turning the upper roller; the other, the little tauter, for turning the lower roller.

3. The pole of the leashes, which runs quite across the chain, takes up all the leashes, and brings them to the workman's hand. These leashes are little strings, tied by a slip-knot to each thread of the chain, to be raised up according as the chain sinks down; they serve to draw the particular thread with which the Weaver wants. He holds the thread separate from the rest, and passes a spindle of such a wood and colour as he thinks proper; then he lets the spindle hang down, and hinders the thread from running off by a slip-knot. After having taken one or two threads of the fore part of the chain by another leesh, he brings the threads of the opposite side to him. By this alternative work he constantly makes them cross one another; and as there are more or less less apart, the greater or less degree of fineness of the intended work. Lastly, the needle is made in form of the common needle, only larger and longer. Its use is to press close the silks when there is any line or colour that does not fit well.

pass the pole of the leashes.

6. The crossrod. 7. A little chain, each loop of which contains four or five threads of the warp, and keeps them perpendicular. 8. An iron hook, to pass the broach, or the crossrod, or the brougher-quill, to pass the threads of the woof, which is wound on it. 10. The comb to strike in the work. 11. The end of the deset let into the roller, in a groove.

When the chain is mounted, the draughtsman traces the principal outlines of the picture, which is to be wrought with black chalk on the fore and back side of the chain. The Weaver in the upright way having prepared a ground, or thread of all the threads of all the colours, goes to work, placed on the back part, as in the flat way, or in the manufacture of the low warp. He has behind him his drawings, on which he frequently looks, that he may find time to time to see how his work succeeds on the right or fore side, which the other cannot do.

TAPIR, a genus of quadrupeds of the order bellus. The generic character is, front teeth in both jaws, ten; canine teeth in both jaws, single, incurved; grinders in both jaws, five on each side, very broad; feet with three hoofs, and a fifth fore foot.

Tapi Herean American, American tapir. The tapir, with respect to the size of its body, may be considered as one of the largest of all the native quadrupeds of South America, except the lately discovered equus bisulcus of Molina, its body being nearly equal to a horse. In its general form it bears some distant resemblance to the hippopotamus, and in the earlier editions of the Systema Naturae was ranked by Linnaeus in that genus, under the title of hippopotamus terrestris. By others it has been considered as more allied to the hog, and has been called cac aquaticus multhius, or water-hog with ingered hoof; but, in reality, the tapir cannot properly be associated, otherwise than by a distant general alliance, with any other quadruped, and forms a peculiar genus. It is of a gregarious nature, and inhabits the woods and rivers of the eastern parts of South America; occurring abundantly in the country of the Amazons; feeding chiefly by night, and eating sugar-canes, grasses, and various kinds of fruit. Its colour is an obscure brown, the skin itself being of that cast, and covered sparingly with somewhat short hair: the young animal is said to be commonly spotted with white. The male is distinguished by a kind of short proboscis or trunk, formed by the prolongation of the upper lip to some distance beyond the lower; this part is extensive, wrinkled at the sides, and in some degree resembles of that the elephant on a smaller scale, though not of the same tubular structure. The neck is very short, and furnished above with a rising mane; the body is thick and heavy; the back much arched; the legs short; the fore feet divided into four toes with pointed hoofs; the hind into three only; the tail is very short, thickish, and bristled. The female is said to be destitute of the proboscis.

In its manners this animal is perfectly harmless; endeavouring merely to save itself by flight when pursued, plunging into some river if at hand, and swimming with great readiness, and even continuing for a considerable time under water, in the manner
of the hippopotamus. The young is easily tamed, and may be rendered domestic, as is said to be the case in some parts of Guiana. In feeding, the tapir makes use in the same manner as the rhinoceros of its upper lip, to grasp the stems of plants, leaves, &c. Its most common activity, when at rest, is sitting on its rump, in the manner of dogs.

The tapir has been occasionally imported alive into Europe. The flesh is considered by the South Americans as a wholesome food, though not very pleasant or delicate, and the skin serves for various purposes where a strong leather is required. The Indians make shields of it, which are said to be so hard that an arrow cannot pierce them. This animal sleeps much by day in the retired parts of the woods, and is shot by the Indians with poisoned arrows. When attacked by dogs, it is said to make a very vigorous resistance. Its voice is a kind of whistle, which is easily imitated, and thus the animal is often deceived and trepanned. It is rather slow in its motions, and of a somewhat inactive disposition.

The tapir produces but one young at a birth, of which it is extremely careful; leading it early to the water, in order to instruct it in swimming, &c. See Plate Nat. Hist. fig. 392.

TAPPING. See SURGERY.

TAR. See Pinus, Resins, and Buiru-zen.

TARANTULA. See Aranea.

TARCHONANTHUS, pter-bane, a genus of plants belonging to the class of cryptogams, and to the order of polygonalas, and in the natural system ranging under the 40th order, composite. The receptacle is villous, and the pappus plukey; the calyx is monophyllous, turbinated, and half divided into seven segments. There are only three species known: the emopinius, glaber, and cricoide.

TARE, is an allowance for the outside package, that contains such goods as cannot be unpacked without detriment; or for the papers, threads, bands, &c. that bind any goods imported loose; or, though imported in casks, chests, &c. yet cannot be unpacked and weighed net.

TARGONIA, a genus of plants of the class of cryptogams, and natural order of algae. The calyx is bivalved, including a globular body. There is only one species; the hypophylla, which is a native of Great Britain.

TARGUM, a name whereby the Jews call the Chaldee paraphrases, or expositions of the Old Testament, in the Chaldean language.

TARIF, or Tariff, a table or catalogue, containing the names of different sorts of merchandise, with the duties to be paid, as settled by authority, among trading nations.

TARUS. See ANATOMY.

TARTAR, or, according to the new chemists, Tartrat, is obtained in a state of impurity, incrusted on the bottom and sides of casks in which wine has been kept. It is afterwards purified by dissolving it in boiling water, and filtering it while hot. On cooling, it deposits the pure salt in very irregular crystals. In this state, it is sold under the name of crystals or cream of tartar. This salt attracted the peculiar attention of chemists, probably in consequence of the eulogies bestowed on it by Paracelsus. It is called tartar, says he, because it produces the oil, water, tincture, and salt, which burn the patient as he puts does. According to him, it is the principle of all the sulfurous, or sulphuric acid. In every remedy, and all things contain the germ of this. This ridiculous theory was combated by Van Helmout, who gives a pretty accurate account of the formation of tartar in wine-casks. It was known to Van Helmout, and even to his predecessors, that potass could be obtained from tartar; but it was long a disputed point among chemists, whether the allah existed in it ready-formed. Duham, Margraf, and Rouelle, at last established that point beyond a doubt; but the other component part of tartar was unknown, or very imperfectly known, till Scheele pointed out the method of extracting it.

The crystals of tartar are very small and irregular. According to Mentat, they are prisms, somewhat flat, and mostly with six sides. Tartar has an acid, and rather unpleasant taste. It is very brittle, and easily reduced to powder. Its specific gravity is 1.03. It is soluble in about 40 parts of cold water, and in about 30 parts of boiling water. It is not altered by exposure to the air; but when its solution in water is allowed to remain for some time, the salt is gradually decomposed, a mucous matter is deposited, and there remains in solution carbonat of potass coloured with a little oil. This decomposition was first accurately described by Berthollet in 1782.

When tartar is heated, it melts, swells, blackens, and the acid is entirely decomposed. The same changes take place when the salt is distilled in close vessels. The phenomena of this distillation have been described by Scheele, distillation was the only method thought of for obtaining any knowledge of the tartric acid. These products are an enormous quantity of gas, consisting of carbonic acid and carburetted hydrogen, an oil, and an acid; and, according to some chemists, carbonat of ammonia. The acid obtained was long considered as a peculiar body, and was denominated pyro-tartaric acid by the French chemists in 1787. But Fourcroy and Vaquelin have lately demonstrated, that it is no other than acetic acid contaminated with a little empyreumatic oil.

Tartar, according to Bergman, is composed of

TARTARIC ACID. Scheele was the first who obtained this acid in a separate state. He communicated a property for obtaining it to Retzias, who published it in the Stockholm Transactions for 1770. It consisted in boiling tartar with lime, and in decomposing the tartrat of lime thus formed by means of hydrochloric acid.

1. The process employed at present for obtaining tartaric acid, which is the same with that of Scheele, is the following: Dissolve tartar in boiling water, and add to the solution powdered chalk, and all effervescences cease, and the liquid ceases to redden vegetable blue. Let the liquid cool, and then pass it through a filter. A quantity of tartar of lime (which is an insoluble white powder) remains upon the filter. Put this tartrat, previously well washed, into a glass cucurbit, and pour in a quantity of sulphoric acid equal to the weight of the chalk employed, which must be diluted with water. Allow it to digest for twelve hours, stirring occasionally. The sulphuric acid displaces the tartrat; sulphat of lime remains at the bottom, while the tartaric acid is dissolved in the liquid part. Decant off this last, and try whether it contains any sulphuric acid. This is detected by a little acetate of lead; a precipitate appears, which is insoluble in acetic acid if sulphuric acid is present, but soluble if it is absent. If sulphuric acid is present, the liquid must be digested again on some more tartar of lime; if not, it is to be slowly evaporated, and about one-third part of the weight of the tartar employed is obtained of crystallized tartaric acid.

2. The form of its crystals is so irregular, that every chemist who has treated of this subject has given a different description of them. According to Bergman, they generally consist of divericating lamelle; according to van Pucken, they assume oftenest the form of long-pointed prisms; Spelimen and Corvinus obtained them in groups, some of them lance-shaped, others needle-formed, others pyramidal. Moreau obtained them needle-like. Their specific gravity is 1.220 to 1.230.

3. Crystallized tartaric acid does not experience any change in the open air, but heat decomposes it altogether: in the open fire it burns without leaving any other residuum than a spongy charcoal, which generally contains a little lime. When distilled in close vessels, it is converted into carbonic acid gas and carburetted hydrogen gas, a coloured oil, and a reddish acid liquor, which was formerly distinguished by the name of pyro-tartaric acid, but which Fourcroy and Vaquelin have lately ascertained to be merely acetic acid impregnated with oil.

4. Tartaric acid dissolves readily in water. Bergman obtained a solution of the specific gravity of which was 1.230. Moreau observed, however, that crystals formed spontaneously in a solution, the specific gravity of which was 1.084. It is not liable to spontaneous decomposition when dissolved in water, unless the solution is considerably diluted.

5. Neither its action on oxygen gas nor on simple combustibles and incombustibles has been examined; but it is probable that it is not capable of producing any volatile change on them. It is capable of oxidizing iron and zinc, and even mercury; but it does not act

11
TAX

upon antimony, bisnuth, tin, lead, copper, silver, gold, or platinum. Its action on the other metallic bodies has scarcely been examined.

6. It combines with alcalis, earths, and metallic oxides, and forms salts known by the name of tartrats.

7. The action of the greater part of the other acids on it is unknown. Hermstid has ascertained, that it may be converted into oxalic acid by distilling it repeatedly with six times its weight of nitric acid. By this process he obtained 360 parts of oxalic acid, from 100 parts of tartaric acid.

8. From this result, and from the product obtained when tartaric acid is distilled, it is evident that it is composed of oxygen, carbon, and hydrogen. Fourcroy informs us, that Vauquelin and he have ascertained that these ingredients are combined in it in the following proportions:

70.5 oxygen
19.0 carbon
10.5 hydrogen

100.0

The affinities of this acid follow the same order as those of oxalic acid.

The crystals in a state of purity, has scarcely been put to any use; but some of the compounds into which it enters are much employed in medicine. This acid has the property of combining in two different proportions with a great number of bases. With potass, for instance, in one proportion, it forms a salt pretty soluble in water, called tartar of potass; but when added in a greater proportion, it forms tartar, a salt very imperfectly soluble in water. By this property, the presence of tartaric acid, in any acid solution, may easily be detected. All that is necessary is, to drop in slowly a little solution of potass; if tartaric acid is present, tartar immediately precipitates in the form of a white gritty precipitate.

TARTRATES, salts formed with the tartaric acid.

TAURUS. See Astronomy.

TAX. See Revenue, Customs, &c.

TAXUS, the Yew-tree, a genus of plants of the class of dicere, and order of monadelphia; and in the natural system ranging under the 31st order, conifer. There is no male calyx or corolla; the staenia are numerous; the anthere petalated and ocellated. The female has no corolla nor style, and only one seed with a calyce resembling a berry very entire. There are four species; of which the buccata, or common yew-tree, is a native of Britain, France, Switzerland, &c. and of North America. It is distinguished from the other species by linear leaves which grow very close, and by the receptacles of the male flowers being subglobose. The wood is reddish, full of veins, and flexible, very hard and smooth, and almost incorruptible. Its hardness renders it very proper for turners and cabinet-makers. Its berries are often eaten by birds, and are therefore not poisonous; but there is a report that the leaves are poisonous to cattle, and many facts are mentioned of horses and cows having eaten them. Others, however, deny these facts. It is of no great height, but the trunk grows to a large size. Mr. Pennant has taken notice of a very remarkable de-
mall tract of land before several persons of the highest rank at the court of France.

It was, however, till the French revolution, that the telegraph was applied generally to useful purposes. M. Chappe, and his colleague, had invented the telegraph first used by the French about the end of 1793, knew any thing of Amonton's invention or not, it is impossible to say; but his telegraph was constructed on principles nearly similar. The manner of using this telegraph was as follows: At the first station, which was on the roof of the palace of the Louvre at Paris, M. Chappe, the inventor, received in writing, from the committee of public welfare, the words to be sent to Lille, near which the French army at that time was. An upright post was erected on the Louvre, at the top of which were two transverse arms, moveable in all directions by a single piece of mechanism, and with inconceivable rapidity. He invented a number of positions for these arms, which stood as signs for the letters of the alphabet; and these, for the greater celerity and simplicity, he reduced in some letters, as follows:

The grammarian will easily conceive that sixteen signs may supply all the letters of the alphabet, since some letters may be omitted not only without detriment but with advantage. The advantage which would be thereupon in the mode of that list could be changed every week; so that the sign of B for one day might be the sign of M the next; and it was only necessary that the person at the extremities should know the key. The instructions to operators were only given in such a manner that those which were so distinct, so marked, so different from one another, that they were easily remembered. The construction of the machine was such, that each signal was uniformly given in precisely the same manner at all stations; it did not depend on the operator's manual skill; and the position of the arm could never, for any signal, be a degree higher or a degree lower, its movement being regulated by pulleys, to the last station.

M. Chappe, having received at the Louvre the sentence to be conveyed, gave a known signal to the second station, which was Mont Martre, to prepare. At each station there was a man or a few men who were fixed, and the person on watch gave the signal of preparation which he had received, and this communicated successively through all the line, which brought them all into a state of readiness. The person at Mont Martre then received, letter by letter, the sentence from the Louvre, which he repeated with his own machine; and this was again repeated from the next height, with inconceivable rapidity, to the final station at Lille.

The first description of the telegraph was brought from Paris to Frankfort on the Maine by a former member of the parliament of Bourdeaux, who had seen that which was erected on the mountain of Belvile. As given by Dr. Hutton from some of the English papers, it is as follows: AAA is a beam or mast of wood placed upright on a rising ground (Plate Miscel. fig. 231), which is about 15 or 16 feet high. BBB is a balance made from the centre AA. This balance-beam may be placed vertically or horizontally, or any how inclined, by means of strong cords, which are fixed to the wheel D, on the edge of which is a double groove to receive the two cords. This balance s about eleven or twelve feet long, and nine inches broad, having at the ends two pieces of wood CC, which likewise turn upon an arm, and are made so that passing through the axis of the main balance, otherwise the balance would derange the cords; the pieces C are each about three feet long, and may be placed either to the right or left, straight, or with the balance-beam. By means of these three the combination of movement is very extensive, remarkably simple, and easy to perform. Below is a small wooden box, in which a person is employed to receive the movements of the machine. On the prominence nearest to this, another person is to repeat these movements, and a third to write them down. The time taken up for each movement is twenty seconds; of which the motion alone is four seconds, the other sixteen the machine is stationary. Two working models of this instrument were executed at Frankfort, and sent by Mr. W. Playfair to the duke of York, and hence the plan and alphabet of the machine was sent to London.

Various experiments were in consequence tried upon telegraphs in this country; and one was soon after set up by government in a chain of stations from the admiralty-office to the sea-coast. It consists of six octagon boards, each of which is pointed upon an axis in a frame, in such a manner that it can be either placed vertically, so as to appear with its full size to the observer at the nearest station as in fig. 232, or it becomes invisible to him by being placed horizontally, as in fig. 233, so that the narrow edge alone is exposed, which narrow edge is from a distance invisible. Fig. 232 is a representation of this telegraph, with the parts all shut, and the machine ready to work; T, in the officer's cabin, is the telescope pointed to the next station. Fig. 233 is a representation of the machine not at work, and with the ports all open. The opening of the first port expresses the letter A, the second B, the third c, the fourth d, the fifth e, the sixth f, &c.

Six boards make 36 changes, by the most plain and simple mode of working; and they will make 27 more if more were necessary; but as the real superiority of the telegraph over all other modes of making signals communicated, is its making it visible, we do not think that more changes than the letters of the alphabet, and the ten arithmetical cyphers, are necessary; but, on the contrary, that those who work the telegraphs should avoid communicating by words or signals agreed upon to express sentences; for that is the sure method never to become expert at sending un(expected intelligence accurately.

This telegraph is, without doubt, made up of the best number of combinations possible; and the second would have been of no use at all, would it have been useless. It has been objected to it, however, that its form is too clumsy to admit of its being raised to any considerable height above the building on which it stands; and that, if it could not to change in direction, and consequently cannot pass from one point to another.

Several other telegraphs have been proposed to remedy these defects, and perhaps others to which the instrument is still liable. The dial-plate of a clock would make an excellent telegraph, as it might exhibit 144 signs so as to be visible at a great distance. A telegraph on this principle, with only six divisions instead of twelve, would be simple and cheap; and might be placed on thirty feet high above the building without any difficulty: it might be supported on one post, and therefore turn round, and the contrast of colours would always be the same.

We shall now conclude this article with a short notice of Mr. John Garnet's most simple and ingenious contrivance. This is merely a bar or plank turned upon a centre, like the sail of a windmill; and being moved into any of the positions, which are the same as the letters or other marks. The consequence is obvious; the telescope being turned round till its wire-covers or becomes parallel to the bar, the index of the former necessarily points at the same letter or mark in its circle, as that of the latter, and the communication of sentiment is immediate and perfect. The use of this machine is so easy, that it has been put into the hands of two common labouring-men, who had never seen it before, and they have immediately held a quick and distant conversation together.

The more particular description and figure of this machine, are as follows. ADIE (fig. 234) is the telegraph, on whose centre of gravity C, about which it revolves, is a fixed pin, which goes through a hole or socket in the arm upright post G, and on the opposite side of which is fixed an index I. Connecting to C, on the same post, is fixed a wooden or brass circle, of six or eight inches diameter, divided into forty-eight equal parts, twenty-four of which represent the letters of the alphabet, and another twenty-four, so that the index, by means of the arm AB, may be moved to any letter or number. The length of the arm should be 24 or 3 feet for every mile of distance. Two revolving lamps of different colours suspended occasionally at A and B, the ends of the arm, would serve equally at night.

Let us (fig. 235) represent the section of the outward tube of a telescope perpendicular to its axis, and the like section of the sliding or adjusting tube, on which is fixed an index L. On the part of the outward tube next to the observer, there is fixed a circle of letters and numbers, similarly divided and situated to the circle in fig. 234; then the index I, in the shape of the same number, is turned so that the index may be turned to any letter or number. Now there being a cross hair, or fine silver wire, fixed in the focus of the eye-glass, in the same direction as the index I; so that when the arm AB (fig. 233) is fixed to the telescope, placed at a distance through the telescope, the cross hair may be turned, by means of the sliding tube, to the same direction of the arm AB; then the index I (fig. 233) will point to the same letter or number, on its own
circle, as the index I (fig. 234) points to on the telegraphic circle.

If, instead of using the letters and numbers to form words at length, they are used as signals, the amount of the information is increased a hundred thousand different signals.

TELEPHIUM, TRUE ORIGIN: a genus of plants of the class of pantandria, and order of trigynia; and in the natural system ranking under the 5-th order, merisculer. The calyx is perfectly lobed, there are five petals, which are inserted into the receptacle; the capsule is unilocular and trivalvular. There are two species, the Imperati and opposition. TEMPLE. See Ottics.

TELLER, an officer of the exchequer, in ancient records called taller; there are four of these officers, whose duty is to receive all sums due to the king, and to give the clerk of the exchequer a bill to charge him therewith. They likewise pull all money due from the king, by warrant from the auditor of the receiver; and make weekly and yearly books, both of their receipts and payments, which they deliver to the lord treas-

TELLINA, a genus of vermes testacese: the generic character is, the animal a tetys; shell bivalve, generally sloping on one side; in the fore-part of one valve a convex, of the other a concave fold; hinge with usually three teeth, the lateral ones smooth in one shell. There are about 100 species, divided into three sections: A ovate and thickish, B ovate and compressed, and C suborbicular. The tellina folicae is of section B, having the shell oval, with rough edges, the flattened sides serrate. It inhabits the Indian Ocean and is rare. See Pl. Nat. Hist. fig. 303.

TELLURIUM, a mineral found in Tansylvania, which Muller of Reichenbach examined in 1782, and concluded, from his experiments, that the ore, which had been distinguished by the names of metallic acidum, aurum paradoxicum, and aurum album, contains a new metal different from every other. Being dissatisfied with his conclusions, he examined by a specimen of it to Klaproth; but the specimen was too small to enable that illustrious chemist to decide the point. He ascertained, however, that the metal in question is not antimony. The experiments of Muller appeared so satisfactory, that they induced Mr. Kirwan, in the second edition of his Mineralogy, published in 1796, to give this metal a separate place, under the name of sylvanian. Klaproth published an analysis of the ore in 179, and completely confirmed the conclusions of Muller. To the new metal, which constitutes 0.925 of the ore, he gave the name of tellurium; and this name has been generally adopted. Gmelin examined the ore in 1799, and his experiments coincide almost exactly with those of Muller and Klaproth. By these philosophers the following properties of tellurium have been ascertained: Its colour is bluish-white, intermediate between gold and lead; its texture is laminated like antimony; and its brilliancy is considerable. Its hardness has not been ascertained. Its specific gravity, according to Klaproth, is 6. It is very brittle, and may be reduced to powder. It melts when raised to a temperature somewhat higher than the fusing-point of lead. If the heat is increased a little, it boils and evaporates, and attaches itself in brilliant drops to the upper part of the retort in which the experiment is made; and it emits a curious and arseneous, the most volatile of all the metals. When cooled slowly, it crystallizes.

When exposed to the action of the blowpipe upon charcoal, it takes fire, and burns with a lively blue flame, the colour of which are green; and it is completely volatilized in the form of a white smoke, which, according to Klaproth, has a smell not unlike that of radishes, but which Gmelin could not observe. This oxide is the oxide of tellurium, which may be obtained also by dissolving the metal in nitro-muriatic acid, and adding potas slowly till the oxide precipitates. This oxide is easily melted by heat into a straw-coloured mass of a radiated texture. When made into a paste with oil, and heated slowly, it changes into charcoal, without changing, with the action of a weight suspended from its extremity. Metals differ exceedingly from each other in tenacity. Iron wire, for instance, both an inch in diameter will stand without breaking, about 5000 lbs. weight; whereas a single strand of lead of the same diameter will not support above 200 lbs.

TENABLE. This word literally means stable. A military column on which was performed in the times of the ancients. In page 206 of Observations on the Military Art, we have the following account of it: A phalang, attacked by a lozenge or triangular wedge, built its right and left forward by a half-quarter conversion, each wing on their common centre; and when they found themselves opposite the sides of the enemy's arrangement, they each marched on their own sole, right before them; by which means they both could face the enemy together, at the same time, while the head was engaged and at blows with the centre of the phalanx that had kept its ground. Such instructions authors have left us of the design and effects of this formation.

The tellurium had considerable advantage over the triangular wedge; but, according to chevalier Foulard, it was not equally efficacious against the column. The latter could alter the direction of its march, and fall upon one of the wings, whether in motion or not, or detach the section of the tail or rear to take its wings in flank, while it was occupied in making the quarter-conversion. The column and talenaid attacked the enemy together, at the same time, while the head was engaged and at blows with the centre of the phalanx that had kept its ground. Such instructions authors have left us of the design and effects of this formation. The tellurium was unquestionably an excellent manoeuvre, and strictly conformable to a very wise maxim, which directs us to multiply our strength and efforts as much as possible against one point. We sometimes, indeed, make use of it in war without being sensible
of its advantages. This, however, does not hinder the manoeuvre from being well performed; for, as the nature of ground and not being level like a sheet of paper, the soldier, in ranging his troops, according to the advantages of the situation, does not form a perfect enfilade, such as may be drawn or sketched out, but one that shall cut the wind, which produces the same effects; and this is what should be sought on all occasions.

**TENAILLES.** In fortification, are low works made in the ditch before the curtains. There are three sorts of them, viz.: the first are the faces of the bastions produced till they meet the more much lower; the second have faces, flanks, and a curtain; and the third have only faces and flanks.

**TENAILLE, single,** a work whose front is advanced towards the country, having two faces, forming a re-entering angle; its two long sides terminate on the counterscarp, opposite to the angle of the shoulder.

**TENAILLE, double,** is a work whose front, having two faces, re-enters, and three salient angles; its long sides are likewise parallel, and terminate on the counterscarp, opposite to the angle of the shoulder. In both the single and double tenailles there is a slight flank or salient, formed at the re-entering angle, because the height of the parapet hinders the soldiers from discovering before that angle. Therefore tenailles should only be made when there is not room enough to make horn-works. The ramparts, parapets, ditches, covert-way, and glacis of tenailles, are the same with other works.

**TENAILLE of a place,** is what is comprised between the points of two neighbouring bastions; as the faces, flanks, and curtains. Hence it is said, the enemy attacked the whole tenaille of a place, when they made no attacks on the faces of the two bastions.

**TENANT,** signifies one who holds or possesses lands or tenements by any kind of right, either in fee, for life, years, or at will.

**TENCH.** See **CYPRINUS**.

**TENDER,** is an offer to pay a debt, or perform a duty. In every plea of tender, where money is the thing demanded by the action, and the debt or duty is not discharged by the tender and refusal, money may be brought in without leave of the court; but, if other things as well as money may, where a tender is pleaded, be brought into court: his is with more propriety called bringing into court generally, than a bringing money into court. In all other cases, the issue of the court must be had before money can be brought into court. The rule under which his leave is granted, is, as in the case of a judgment by a mortgagee, founded upon a particular act. In other acts, as, for instance, the rule is founded upon that discretionary power, which is, for the furtherance of justice, vested in the court. By the discretionary rule, it is sometimes ordered, that upon bringing money into court, all proceedings in action shall be stayed. At other times it is ordered, that the money brought into court shall be stuck out of the plaintiff's declaration, and at the plaintiff shall not, at the trial of the case, be permitted to produce evidence as to this money. This rule, by which the money brought into court is ordered to be struck out of the declaration, is from its being more Vol. II. frequently granted, than that by which it is ordered, that the proceeding shall be stayed, called the common rule. 5 Bac. Abr. 1.

If bank notes have been offered, and no objection made on that account, it has been considered by the court of king's bench as a good tender. 3 Durnf. and East, 554.

**TENDER, small ship in the service of men of war, for carrying of men, provisions, or any thing else that is necessary.**

TENDONS, are white, firm, and tenacious parts, continuous to the muscles, and usually forming their extremities.

**TENEBRIO, a genus of insects of the order Coleoptera.** The general character is, antennae moniliform, with the last joint rounded; thorax plano-convex, margined; head exserted; wing-sheaths stiltish. In this genus, of which there are more than 100 species, the body is obovate-oval, and in most species somewhat pointed at the extremity; it may be observed also that several species are destitute of wings. Among the European tenebriones one of the most remarkable is the *tenebrio monolopis,* a black insect measuring about an inch in length, with powerful short antennae, which, while at their extremities project a little beyond the body; this insect also perfectly connotes and undivided, forming a complete covering to the body, being carried over the sides to some distance beneath, and the insect is totally destitute of real or under wings. It is usually found in dark, neglected places, beneath boards, in cellars, &c.; and, if handled, especially if crushed, diffuses a highly unpleasant smell.

**Tenebrio globosus** is perhaps not a Linnean species, unless it is the *tenebrio* globosus of that author. It is seen in the hottest part of the summer about walls and pathways, and is distinguished by the remarkably globular appearance of the body; it is totally black, the under parts having sometimes a slight violaceous cast, and the joints of the feet, which are remarkably broad, are of a dull brown: the whole insect is of a very smooth, but not polished, surface, and usually measures about three quarters of an inch in length; in the winter it varies considerably, some specimens, probably the males, being considerably smaller. The antenna in this insect are beautifully moniliform, all the joints being globular.

**Tenebrio modicor** is an insect often seen in houses; it is one of the smaller kinds, and is coal-black, of a lengthened shape, with longitudinally striated wing-shells, and proceeds from a larva commonly known by the name of the meal-worm, from its being frequently found in flour, &c. It is of a yellowish white colour, about an inch long, slender-bodied, and of a highly polished surface, and is considered as the favorite food of the night- ingale when kept in a cage of captivity: it is said to remain two years before it hanges into a chrysals.

The genus *tenebrio* is numerous, and some of the exotic species much resemble the general appearance of those in Europe, but are much larger. Many others are small insects, and the genus has received, by later discoveries, such ascensions, that it has been divided into several distinct genera.

**TENEMENT.** In the common acceptation, is applied only to houses and other build-ings; but in its original, proper, and legal sense, it signifies every thing that may be held, provided it is of a permanent nature, whether it is of a substance, or of an unsubstantial and ideal kind. Thus frank tenement, or freehold, is applicable not only to lands and other solid objects, but also to offices, rents, commons, &c., and as lands and houses are tenements, so is an advowson a tenement; and a franchise, or office, a right of common, a peerage, or other property of the like unsubstantial kind, are all of them, legally speaking, tenements. 2 Black. 17.

**TENEMENTS LEGATIS, a writ that lies to London, or any other corporation;** is that men may dempe tenements as well as goods and chattels by their last will, for the hearing any controversy touching the same, and for rectifying the wrong.

**TENESMUS.** See **MEDICINE.**

**TENNIS,** a play at which a ball is driven by a racket, and the persons who would become players at tennis, provided they understand the rudiments of the game, as to form some judgment of the players, or at least to know who wins and who loses, we may presume to give so plain a description of it, that no one can make a loss, if ever he should bet or play. As to the executive part, it requires great practice to make a good player, so that nothing can be done without it; all we presume to do, is to give an insight into the game, by which a person may not see a total stranger to it when he happens to be in a tennis-court.

The game of tennis is played in most capital cities in Europe, particularly in France, where the custom is to derive its origin. It is esteemed with many to be one of the most antient games in Christendom, and long before king Charles I.'s time it was played in England.

This game is as intricate as any game whatever; a person who is totally ignorant of it may look on for a month together, without being able to make out how the game is decided. We shall begin therefore by describing the court in which it is played.

The size of a tennis-court is generally about 99 or 97 feet by 33 or 34, there being no exact dimension ascribed to its proportion, a foot more or less in length or width being of no consequence. A line or net hangs exactly across the middle, over which the ball must be struck, either with a racket or board, to make the stroke good. Upon the entrance of a tennis-court, there is a long gallery which goes to the dens, that is, a kind of front gallery, where the spectators usually stand; into which whenever the ball is struck, it tells for a certain stroke. This long gallery is divided into different compartments or galleries, each of which has its particular name, as follows; from the line towards the dens are the first gallery, door, second gallery, and the last gallery, which is called the service side. From the dens to the last gallery are the figures 1, 2, 3, 4, 5, 6, at a yard distance, which the chaces are marked, and is one of the three long parts of the game, as will appear in the following description.

On the other side of the line are also the first gallery, door, second gallery, and last...
TENNIS.

The chances on the hazard-side proceed from the ball being returned either too hard or not quite hard enough; so that the ball after its first rebound falls on this side of the blue line, or line which describes the hazard-side chaces; in which case it is a chance at 1, and there is no chance depending.

When they change sides, the players, in order to win this chance, must put the ball over the line in any way, so that his adversary cannot return it. When there is no chance on the service-side, the players put over the line from the service-side, without being returned, reckon for a stroke.

As the game depends chiefly upon the marking, it will be necessary to explain it, and to recommend those who play at tennis to have a good and unbiased marker, for on him the whole set may depend: he can mark in favour of the one and against the other in such a manner, as will render it two to one to the first player, starting, though even played. Instead of which the strokes should be very attentive to the chaces, and not be any way partial to either of the players.

This game is marked in a very singular manner, which makes it at first somewhat difficult to understand. The first stroke, third, third 30, the third 40, and the fourth game, unless the players get four strokes each; in that case, instead of calling it 40 all, it is called deuce; after which, as soon as any stroke is got, it is called advantage; and when the strokes become equal again, deuce again, till one of the other gets two strokes following, which win the game; and as the games are won, they are marked and called; as one game, two games, and so to one, &c. towards the set, of which so many of these games it consists.

Although but one ball at a time is played with, a number of balls are made use of at this game to avoid trouble, and are handed to the players in baskets for that purpose; by which means they can play as long as they please without ever having occasion to stop for a ball.

As to the odds at tennis, they are by no means fixed, but are generally laid as follow:

Upon the first stroke being won between even players, that is, fifteen love, the odds of the single game 7 to 4

<p>| | |</p>
<table>

The odds of a four-game set when the first game is won, are 3 to 2.

When two games love | 4 1
Three games love | 2 1
When two games to one Three games to one | 2 1

The odds of a six-game set when the first game is won, are 2 to 1.

When two games love | 4 1
Four games love | 1 1
Five games love | 2 1
When two games to one Three games to one | 2 1
Four games to one | 2 1
Five games to one | 2 1
When three games to two Four games to two | 4 1
Five games to two | 2 1
When four games to three Five games to three | 2 1
The odds of an advantage-set when the game is won by the player, are 2 to 1.

When two games love | 3 1
Three games love | 1 1
Four games love | 1 1
Five games love | 2 1
Three games to one | 2 1
Four games to one | 2 1
Five games to one | 2 1
When three games to two Four games to two | 4 1
Five games to two | 2 1
When four games to three Five games to three | 2 1
When five games to four Five games to five | 2 1
When six games to five | 2 1

The foregoing odds, as beforefised, are general laid; but the chaces intezner make the odds very precarious; for example, when there is a chance at half a yard, and a set is five games all, and in every other respect equal, the odds are a good five to four; and if it were six games five, and forty thirty, with the same chace, the odds would then be a guinea to a shilling; so that it is plain that the odds at this game differ from those of any other; for one stroke will ruin the set, that is, it will take all the five games all, from an even wager to three to two, and so in proportion to the stage of the set.

There are various methods of giving odds at tennis, in order to make a match equal; and that they may be understood, we shall give the following list of them, with their respective meanings, so that any person may form a judgment of the advantage received or given.

The lowest odds that can be given, excepting the choice of the side, is what they call a bisque, that is, a stroke to be taken or scored whenever the player, who receives the advantage, thinks proper: for instance, suppose a critical game of the set to be forty thirty, by taking the stroke of forty thirty, they give the adversary so in respect of two bisques, &c.

The next greatest odds are fifteen, that is, a certain stroke given at the beginning of each game.

After these, half thirty, that is, fifteen one game, and so on to the next. Then follow the whole thirty, forty, &c.

There are also the following kind of odds which are given, viz. Round services: those are services given round the penthouse, so as to render it easy for the players to return it.

Half-court, that is, being obliged or confined to play within the compass of the walls, or sides of the court. This is a considerable advantage, given by him so confined, but the straight half-court is the greatest.

Touch-no-wall, that is, being obliged to play within the compass of the walls, or sides of the court. This is a considerable advantage, given by him so confined, but the straight half-court is the greatest.

Touching the hazards, that is, barring the dedans, gallery, or the last gallery on 9.
the hazard-side, or any particular one or more of them.

There are the common kind of odds or advantages given; but there are many others, which are according to what is agreed by the players; such as playing with board against racket, cricket-bat against racket, &c.

The guard is a weapon played by four persons, two partners on each side. In this case, they are generally confined to their particular quarters, and one of each side appointed to serve and strike out; in every respect, the game is played in the same manner as when two only play.

Any thing more to be said upon this subject would be needless, as nothing can be recommended, after reading this short account of tennis, but practice and attention, without which no one can become a proficient at the game.

TENON, in building, &c. the square end of a piece of wood, or metal, diminished by one-third of its thickness, to be received into a hole in another piece, called a mortise, for jointing or fastening the two together. It is made in various forms, square, dove-tailed, for double mortises, &c.

TENOR, of writing, &c. is the substance or purport of them, or a transcript or copy.

TENOR, in music, the second of the four parts in harmonical composition, reckoning from the bass. The tenor is the part most accommodated to the common voice of man, from which circumstance it has sometimes, by way of preference, been called "the human voice." Its general compass extends from C above G to G the treble-cliff note.

The tenor was formerly the plain-song, or principal part in a composition, and derived the name of tenor from the Latin word teno, I hold; because it held or sustained the air, point, substance, or meaning, of the whole cantus, and every part superadded to it was considered but as its auxiliary. It appears that the contrary practice of giving the air to the soprano, or treble, had its rise in the tendency of the ancient music to revolve musical themes round a central point, and to introduce them into musical performances; since which it has been universally adopted both in vocal and instrumental music.

TENOR-CLIFF, the name given to the C cliff when placed on the fourth line of the slave. See CLIFF.

TENOR VIOIN, or Viola, a stringed instrument resembling the violin, but lower in its scale, having its lowest note in C above G gamut. In concert this instrument takes the part next above the bass.

TENSE, tense, in grammar, an inflection of verbs, wherein they are made to signify or distinguish the circumstance of time, in what they affirm.

TENSION, the state of a thing stretched. Thus animals sustain and move themselves by the tension of their muscles and nerves. A chord or string gives an acute or deeper sound, as it is in a greater or less degree of tension, that is, more or less stretched or tightened.

TENT, in surgery, a roll of lint worked into the shape of a nail, with a broad flat head. See LINT, LINT-ROLL.

TENTER, a railing used in the cloth-manufacture, to stretch out the pieces of cloth, stuff, &c. or only to make them even, and set them square. It is usually about four feet in length, and exceeds that of the longest piece of cloth. It consists of several long pieces of wood, placed so that the lower cross-piece of wood may be raised or lowered, as is found requisite, to be fixed at any height, by means of pins. Along the cross-pieces, both the upper and under one, are hooked nails, called tenter-hooks, driven in from space to space.

TENTHREDO, a genus of insects of the order hymenoptera. The generic characteristic is, mouth with jaws, without proboscis; wings flat, swelled or slightly inflated; piercer consisting of two serrated and scarcely projecting lamine; scutellum with two distant granules. The larvae of the genus are remarkable for their great resemblance to those of the order lepidoptera or real caterpillars, from which however they may in general be readily distinguished by their more numerous feet, which are never fewer than sixteen, exclusive of the three first or thoracic pairs. When disturbed or handled, they usually roll themselves into a flat spiral. They feed, like the caterpillars of the lepidoptera, on the leaves of plants, and undergo their metamorphosis in very much the same case or enclopmen, prepared in autumn, out of which in the ensuing spring emerges the complete insect.

The tenthredines form a very numerous genus, and may be divided into tribes or sections, according to the form of the antenna, which are in some cladaved, in others filiform, &c. Among the principal species may be numbered the tenthredo lutea of Linnaeus, which anocedes from a large twin larva, of a finely granulated surface, with a double row of black specks along each side, and a dusky dorsal line bounded on each by yellow: it feeds on various species of willow, &c. The parchment-case in which it envelops itself in autumn is of a pale yellowish-brown colour, and the chrysalis, which is of a pale dinsky or brownish cast, exhibits the limbs of the future fly, which is equal in size to a common caterpillar, and of a yellow colour, barred with black: the antenna rather short, and strongly cladaved.

The tenthredo americana of Linnaeus is somewhat smaller than the preceding, and of a cinnamon-brown colour, with the under part of the abdomen rusous or dull orange: like the former, its caterpillar is of a green colour, and of a finely roughened surface covered with numerous whitish specks.

The larvae of the smaller tenthredines are often very injurious to different kinds of exculent vegetables, as turnips, &c. &c. There are nearly 200 species of this insect.

TENTHS, that yearly portion or tribute which all ecclesiastical livings antiently paid to the king, but in the tenure of this word, which is a very extensive one, is usually restrained by coupling other words with it: this is sometimes done by words which denote the duration of the tenant's estate; as if a man held them 100 years, it is called tenure in fee-simple. At other times the tenure is coupled with words pointing out the instrument by which an inheritance is held: thus, if the holding is by copy of court roll, it is called tenure by court roll.

At other times, this word is coupled with other words that shew the principal service by which an inheritance is held: as where a man held by knight's service, it is called tenure by knight's service.

TERANUS, a genus of the phaladiace decandria class and order of plants: the keel is very small, concealed within the calyx; stamina alternate, five, barren; stigma sesile, there are two species, creeping plants of Jamaica.

TEREBELLA, a genus of vermes molusca. The generic characteristic is, body oblong, creeping, naked, often enclosed in a tube furnished with lateral tufts and branches; mouth placed before, furnished with lips, without teeth, and protending a clavate proboscis; feelers numerous, ciliate, capillary, seated round the mouth. There are eleven species.

TEREDO, in natural history, a genus of vermes belonging to the order of lepideacae. The animal is a tenerry; there are two valves, calcareous, hemispherical, and cut off before, and two lanceolated. The shell is minute, exuding, and tapering, and furnished with a hard wood. There are only three species, the navalis, urticulis, and clava. See Plate Nat. Hist. fig. 394.

The navalis, or ship-worm, which has a very slender smooth cylindrical shell, inhabits the Indian seas, whence it was imported into Europe. It penetrates easily into the stoutest oak-planks, and produces dreadful destruction to the ships by the holes it makes in their sides; and it is to avoid the effects of this insect that vessels require sheathing.

The head of this creature is well prepared by nature for the hard offices which it has to undergo, being coated with a strong armour, and furnished with a mouth like that of the leech, by which it pierces wood as that animal does the skin. A little above this it has two horns which seem a kind of continuation of the shell; the neck is as strongly provided for the reception of the proboscis as the head, being furnished with several strong muscles; the rest of the body is only covered by a very thin and transparent skin, through which the motion of the intestines is plainly seen by the naked eye; and by means of the microscope several other very remarkable particulars become visible there. This creature is wonderfully minute when newly excluded from the egg; but it grows to the length of four or six inches, and sometimes more.

When the bottom of a vessel, or any piece of wood which is constantly under water, is inhabited by these worms, it is full of small holes; but no damage appears till the outer parts are cut away; then their shells habitually come into view. These animals are capable of forming such large space for enclosing the animal, and surrounding it with water. There is an evident care in these creatures never to injure one another's habitations, by which means each case is preserved, and extended in such pieces of wood as have been found eaten by them into a sort of honeycomb, there never is seen a passage or communication between any two of the shells, though the woody structure from them either without or below a piece of writing-paper. They penetrate some kinds of wood more easily than others.
They make their way most quickly into fir and alder, and grow to the greatest size. In the oak they make small progress, and appear squatter and blebile, and their shells much discoloured.

Since each of these animals is lodged in a solitary cell, and has no access to those of its own species, it has been matter of surprise how they should increase to so vast a multitude. Upon dissecting them, it appears that every individual has the parts of both sexes, and is therefore supposed to propagate by itself.

The sea-worms, which are pernicious to our shipping, appear to have the same office allotted to them in the waters which the termites have on the land (see Termes). They will appear, on a very little consideration, to be most important beings in the great chain of creation, and pleasing demonstrations of that infinitely wise and gracious Power which formed, and still preserves, the whole in such wonderful order and beauty; for if it was not for these and such animals, tropical rivers, and indeed the ocean itself, would be choked with the bodies of trees which are annually carried down by the rapid torrents, as many of them would last for ages, and perhaps centuries. Of which, happily, we cannot in the present harmonious state of things form any idea; whereas now being consumed by these animals, they are more easily broken in pieces by the waves; and the fragments which do not disintegrate become specifically lighter, and are consequently more readily and more effectually thrown on shore, where the sun, wind, insects, and various other instruments, speedily promote their entire dissolution.

TERMES. See Anatomy.

TERM, in geometry, is the extreme of any magnitude, or that which bounds and limits its extent. So the terms of a line, are points; of a superficies, lines; of a solid, superficies.

Terms, of an equation, or of any quantity, in algebra, are the several names or members of which it is composed, separated from one another by the signs + or −. So, the quantity \( 2a + 3b - 3x \), consists of the three terms \( a \), \( 3b \), and \( -3x \). In an equation, the terms are the parts which contain the several powers of the same unknown letter or quantity; for if the same unknown quantity is found in several members in the same degree or power, they shall pass but for one term, which is called a compound one, in distinction from a simple or single term. Thus, in the equation

\[
\begin{align*}
x^2 + 4a - 3b &= 0, \\
x &= a - \frac{3b}{x},
\end{align*}
\]

the four terms are \( x^2 \), \( 4a \), \( -3b \), and \( a - \frac{3b}{x} \); of which the second term \( a - \frac{3b}{x} \) is compound, and the other three are simple terms. To express a product, or of a fraction, or of a ratio, or of a proportion, &c. are the several quantities employed in forming or composing them. Thus, the terms of the product \( ab \), are \( a \) and \( b \); of the fraction \( \frac{a}{b} \), are \( a \) and \( b \); of the ratio \( a:b \), are \( a \) and \( b \); of the proportion \( a:b = c:d \), are \( a, b, c, \) and \( d \).

Terms, are those spaces of time wherein the courts of justice are open for all that complain of wrongs or injuries, and seek their rights by course of legal action, in order to their redress; and during which, the courts in Westminster-hall sit and give judgments, &c. but the high court of parliament, the chancery, and inferior courts, do not observe the terms; only the courts of king's-bench, common pleas, and exchequer, the highest courts at common law. Of these terms there are four in every year, viz: Hilary term, which begins the 23d of January, and ends the 12th of February, unless on Sundays, and then the day after; Easter term, which begins the Wednesday next after Easter-day, and ends the Monday next after Ascension-day; Trinity term, which begins the Friday after Trinity Sunday, and ends the Wednesday next after; and Michaelmas term begins the 6th and 7th of September.

There are in each of these terms stated days, called days in bank, that is, days of appearance in the court of common pleas, called usually bancum, or commune bancum, to distinguish it from bancum regis, or the court of king's-bench. They are generally at the distance of about a week from each other, and regulated by some festival of the church. On some of these days in bank, all original writs must be returnable, and therefore they are generally called the return of that term. 3 Black 227.

The first return in every term is, properly speaking, the first day in that term; and in the case of errors, extremely rare, of which happily, we cannot in the present harmonious state of things form any idea; whereas now being consumed by these animals, they are more easily broken in pieces by the waves; and the fragments which do not disintegrate become specifically lighter, and are consequently more readily and more effectually thrown on shore, where the sun, wind, insects, and various other instruments, speedily promote their entire dissolution.

TERMES. See Anatomy.

TERM, in Oxford. Hilary, or Lent term, begins on Jan. 14, and ends the Saturday before Palm Sunday. Easter term begins the tenth day after Easter, and ends the Thursday before Whit Sunday. Trinity term begins the Wednesday after Trinity Sunday, and ends after the act, sooner or later, as the vicar-chancellor of the place, Michaelmas term begins on Oct. 10, and ends Dec. 16.

TERMES, the white ant, a genus of insects of the order apetera; the generic character is, legs six, formed for running; eyes two; antennæ simple; mouth furnished with two jaws. The different species of living termites are very small, compared with those of the warmer regions of Africa and America; and instead of assembling in multitudes, as in those climates, are usually observed single. The same is observable in the termite, Pulsatorius of Linnaeus, a diminutive insect, of a whitish colour, and which, from its general resemblance to the insects of that genus, has by Derham and some other naturalists been distinguished by the title of a species, but I am of opinion that it is much more frequent, during the summer months, in houses, particularly where the wainscot is in any degree decayed, and is remarkable for causing a long-continued sound, exactly resembling the ticking of a watch. It is a very common insect in collections of dried plants, &c. which it often injures greatly. It is of so tender a frame as to be easily destroyed by the slightest pressure, and is an animal of very quick motion, which makes it very hard to find; it is small, and bears a complete resemblance to a common mite, being furnished with eight legs, and beset with long hairs. After a certain time it casts its skin, and appears in the very different form of a decider kind. Some individuals of this species become winged when arrived at their full growth; the wings, which are four in number, being very large, of a slightly indescent appearance, and variegated with blackish and brown clouds or spots. It is in the beginning of July that this change takes place, and at this time several may be seen with the wings half-grown; in a few days they seem to obtain their full size.

Mr. Derham imagines the ticking sound which these animals produce, to be analo-

gous to the call of birds to their mates during the breeding-season; and there seems to be no reason to call a species by the truth of this observation. We may add, that this sound, as well as that produced by the pinus fati-

dicus, or death-watch, seems to afford a con-

vincing proof of the faculty of hearing in insects, which some naturalists have been inclined to deny.

Of the exotic termites the most remarkable seems to be the termes bellicosus, whose his-

tory is described by Mr. Smeathman in the Philosophical Transactions.

With the good order of their subterranean cities, they will appear foremost on the list of the wonders of the creation, as most closely imitating mankind in provident industry and regular government, and being by nature, and by manner of living, which is in large communities that erect very extraordinary nests, for the most part on the surface of the ground, whence their excursions are made through subterranean passages covered with galleries, which they build whenever necessity obliges, or plunder in-

duces, to march above ground; and at
a great distance from their habitations carry on a business of depredation and destruction, scarcely credible but to those who have seen it.

The termites resemble the ants also in their provident and diligent labour, but surpass them as well as the bees, wasps, andr, and all other animals, in the arts of building; as much as if any other and other cultivated savages. It is more than probable they exceed them as much in sagacity and the arts of government; it is certain they shew more substantial instances of their ingenuity and industry, than any other animals; and do in fact lay up vast magazines of provisions and other stores; a degree of prudence which has of late years been denied, perhaps without reason, to the ants.

Their communities consist of one male and one female (who are generally the common parents of the whole, or greater part, of the rest); and of three order of insects, apparently of very different species, but really the same, which together compose great commonwealths, or rather monarchies, if we may be allowed the term.

The different species of this genus resemble each other in form, in their manner of living, and in their good and bad qualities, but differ as much as birds in the manner of building their habitations or nests, and in the choice of the materials with which they compose them.

There are some species which build upon the surface of the ground, or part above and part beneath; and one or two species, perhaps more, that build on the stems or branches of trees, sometimes aloft at a vast height. Of every species there are three orders: first, the working insects, which, for brevity, we shall generally call labourers; next the fighting ones, or soldiers, which do no kind of labour; and last, of all the winged ones, or perfect insects, which are male and female, and are now much less numerous than the first two.

The nests of the termites bellicosus are so numerous all over the island of bananas, and the adjacent continent of Africa, that it is scarcely possible to stand upon any open place, such as a plantation, or other clearing, where one of these buildings is not to be seen within fifty paces, and frequently two or three are to be seen almost close to each other. In some parts near Senegal, as mentioned by M. Altonson, their number, magnitude, and closeness of situation, make them appear like the villages of the natives.

These buildings are usually termed hills, by natives as well as strangers, from their outward appearance, which is that of little hills more or less conical, generally pretty much in the form of sugar-loaves, and about ten or twelve feet in perpendicular height above the common surface of the ground.

These hills continue quite bare until they are six or eight feet high; but in time the dead barren clay, of which they are composed, becomes fertilized by the genial power of the elements in these proclive climates, and the addition of other materials, brought by the wind; and in the second or third year, the billock, if not over-shadowed by trees, becomes, like the rest of the earth, almost covered with grass and other plants; and in the fourth year it may be burnt by the rays of the sun, it is not much unlike a very large lady-cock.

Every one of these buildings consists of two distinct parts, the exterior and the interior. The exterior is composed of a number of dome, large and strong enough to inclose and shelter the interior from the vicissitudes of the weather, and the inhabitants from the attacks of natural or accidental enemies. It is always, therefore, much stronger than the interior, which is the habitable part, divided with a wonderful kind of regularity and contrivance into an amazing number of apartments for the residence of the king and queen, and the nursing of the young. In the latter there is a small space for the magazines, which are always found well filled with stores and provisions.

From these habitations, galleries again ascend, and lead out horizontally on every side, and are carried under ground near to the surface a vast distance; for if you destroy all the nests within one hundred yards of your house, the inhabitants of those which are left unmolested farther off, will nevertheless carry on their subterranean proceedings, and invade the goods and merchandises contained in it by sap and mine, and do great mischief if you are not very circumspect.

It has been observed, that there are of species of these insects; of some of these orders the working insects or labourers are always the most numerous; in the termites bellicosus there seems to be at least one hundred labourers to one of the fighting insects. The state of one-fourth of an inch long, and twenty-five of them weigh about a grain; so that they are not so large as some of our ants. The second order, or soldiers, have a very different form from the labourers, and have been by some authors supposed to be the males, and the former neutrals; but they are, in fact, the same insects, only they have undergone a change of form, and approached one degree nearer to the perfect state. They are now much less numerous than the males, and equal in bulk to fifteen of the labourers.

There is now likewise a most remarkable circumstance in the form of the head and mouth; for in the former state the mouth is evident, and the jaws and holding-beads; but in this state, the jaws being shaped just like two very sharp awls, a little jagged, they are incapable of any thing but piercing or wounding, for which purposes they are very effectual, being as hard as a crab's claw, and placed in a strong horned head, which is of a nut-brown colour, and larger than all the rest of the body together, which seems to labour under great difficulty in carrying it; on which account perhaps the animal is incapable of climbing up perpendicular surfaces.

The third order, or the insect in its perfect state, varies its form still more than ever.

The head, thorax, and abdomen, differ almost entirely from the same parts in the labourers and soldiers; and, besides this, the animal is now furnished with four fine large brownish, transparent, wings, with which it is at the time of emigration to wing its way in search of a new and perhaps more suitable place, to make their nests without finding one winged insect, for those are to be found only just before the commencement of the rainy season, when they undergo the last change, which is preparatory to their hibernation.

In the winged state they have also much altered their size as well as form. Their bodies now measure between six and seven tenths of an inch in length, and their wings a foot above two inches, and from tip to tip they are equal in bulk to about thirty labourers, or two soldiers. They are now also furnished with two large eyes placed on each side of the head, and very conspicuous: if they have any force, they are not easily to be distinguished. Probably in the two first states, their eyes, if they have any, may be small, like those of moles, for as they live, like these animals, always under ground, they have as little occasion for these organs, and it is not to be wondered at that we do not discover them; but the case is much altered when they arrive at the winged state in which they are to roam, though but for a few hours, through the wide air, and explore new and distant regions. In this form the animal comes abroad during, or soon after, the first tornado, which, at the latter end of the dry season, proclaims the approach of the ensuing rains, and seldom waits for a second or third shower, if the fire, as is generally the case, happens in the night, and brings much wet after it.

The quantities that are to be found the next morning will go over the surface of the earth, as well as the earth itself, more, or very little, as is necessary for their wings are only calculated to carry them a few hours, and after the rising of the sun not one in a thousand is to be found with four wings, unless the morning continues very rainy, and then and then the animal is seen winging its way from one place to another, as if solicitous only to avoid its numerous enemies, particularly various species of ants which are hunting on every spray, on every leaf, and in every possible place, for this unhappy race, of which probably not a pair in many millions get into a place of safety, fulfill the first law of nature, and lay the foundation of a new community.

The termites arboreus, those which build in trees, frequently establish their nests within the roofs and other parts of houses, to which they do considerable damage, if not timely extirpated. The large species are not only much the most destructive, but more difficult to be guarded against, since they make their approaches chiefly under ground, descending below the foundations of houses and stores at several feet from the surface, and rising again either in the houses, or entering at the bottoms of the posts, of which the sides of the buildings are composed, bore quite through them, following the course of the fibres to the top, or making lateral perforations and cavities here and there as they proceed.

While some are employed in gutting the posts, others ascend from them, entering a ratter or some other part of the roof. If they once find the thatch, which seems to be a favourite food, they soon bring up wet clay, and build their pipes or galleries through the roof in various directions, as long as it will support them; sometimes eating the palm-tree leaves and branches of which it is composed, and perhaps sand, which is very pleasing to them, the rattan, or other running plant, which is used as a cord to tie the various parts of the roof together, and that to the posts which support it; thus, with the assistance of the rain, which during the rainy season are apt to shelter themselves there, and to burrow through it, they very soon ruin.
the house by weakening the fastenings, and exposing it to the weat. In the mean time the posts will be perforated in every direction, as full of holes as that timber in the bottoms of ships which has been bored by the worms; the fibres and knotty parts, which are so prominent, being left to the last.

They sometimes, in carrying on this business, seem to find that the post has some weight to support, and then if it is a convenient track to the roof, or is itself a kind of wood again, they bring their mortar, and all or most of the cavities leaving the necessary roads through it, and as fast as they take away the wood, replace the vacancy with that material; which being worked together by them closer and more compactly than human strength or art could ram it, when the house is pulled to pieces, in order to examine if any of the posts are fit to be used again, those of the softer kinds are often reduced almost to a shell, and all or a greater part of the timber, from wood to the core, as in and as hard as many kinds of free-stone used for building in England. It is much the same when the termites bellicose get into a chest or trunk containing clothes and other things: and if the house is great, or they are afraid of ants or other enemies, and have time, they carry their pipes through, and replace a great part with clay, running their galleries in various directions. The tree termites indeed, when they get within a box, often make a nest there, and being once in possession, destroy it at their leisure.

When the termites attack trees and branches in the open air, they sometimes work at a great rate of doing it. If a stake in a hedge that has not taken root and vegetated, it becomes their business to destroy it. If it has a good sound bark round it, they will enter at the bottom, and eat all but the bark, which will remain, and exhibit the appearance of a solid stick (which some vagrant colony of ants or other insects often shelter in till the winds disperse it); but if they cannot trust the bark, they cover the whole stick with mud, and then it loses, as if it had been dipped into thick mud that had been dried on. Under this covering they work, leaving no more of the stick and bark than is barely sufficient to support it, and frequently not the smallest particle; so that upon a very small tap with your walking-stick, the whole stake, though apparently as thick as your arm, and five or six feet long, loses its form, and disappearing like a shadow, falls in small fragments at your feet.

The first object of admiration which strikes one upon opening their hills, is the behaviour of the soldiers. If you make a breach in a slight part of the building, and do it quickly with a strong hoe, or pick-axe, in the space of a few seconds a soldier will run out, and walk about the breach, as if to see whether the enemy is gone, or to examine what is the cause of the attack. He will sometimes go again, as if to give the alarm; but generally, in a short time, he is followed by a large body, who rush out as fast as the breach will permit them; and so they proceed, the number increasing, as long as any one continues battering their building. It is not difficult to describe the rage and fury they show. In their hurry they frequently miss their hold, and tumble down the sides of the hill, but recover themselves as quickly as possible; and, being blind, bite every thing they run upon, and make a cracking noise, while some of them beat repeatedly with their forces upon the building, and make a small vibrating noise, something shriller and quicker than the ticking of a watch. If they get hold of any one, they will in an instant let out blood enough to weigh against their whole body; and if it is the leg they wound, you will see the stain upon the stocking extend an inch in width. They make their hooked jaws meet at the first stroke, and with that hold, but suffer themselves to be pulled away leg by leg, and piece after piece, without the least attempt to escape. On the other hand, keep out of their way, and give them no interruption, and they will in less than half an hour retire into the nest, as if they supposed the wonderful monster that damaged their castle to be gone beyond their reach. Before they are all got in you will see the labourers in motion, and beginning to vary their directions toward the breach, every one with a burthen of mortar in his mouth ready-tempered. This they stick upon the breach as fast as they come up, and do it with so much dispatch, that, though there are thousands, or rather millions, of them, they never stop or embarrass one another; and you are most agreeably deceived, when, after an apparent scene of hurry and confusion, a regular precision, gradually filling up the chasm. While they are thus employed, almost all the soldiers are retired quite out of sight.

A renewal of the attack, however, instantly changes the scene. At every stroke we hear a loud hiss; and on the first the labourers run into the many pipes and galleries with which the building is perforated, which they do so quickly that they seem to vanish, for in a few seconds all are gone, and the soldiers rush out as numerous and as victoriously as before.

Previously to breeding, a very surprising change takes place in the body of the queen or breeding animal. The abdomen of this female, in the spring, especially, gradually extends and enlarges to the enormous size, that an old queen will have increased so as to be fifteen hundred or two thousand times the bulk of the rest of her body, and twenty or thirty thousand times the bulk of a labourer. Mr. Smethurst conjectures the animal is upwards of two years old when the abdomen is increased to three inches in length, and has sometimes found them of near twice that size. The abdomen is now of an irregular oblong shape, being contracted by the muscles of every segment, and is become one vast matrix full of eggs, which make long circumvolutions through an immovable quantity of very minute vessels that circulate round the inside in a serpentine manner, which would exercise the ingenuity of a skilful anatomist to dissect and develop. This singular matrix is not more than two or three inches in length and size, than for its persistal nectar, which resembles the undulating of waves, and continues incessantly without any apparent effort of the animal; so that one part or other alternately is rising and sinking in perpetual succession, and the matrix seems never to rest, but is always protruding eggs to the amount of sixty in a minute, or eighty thousand and upward in one day of twenty-four hours. These eggs are instantly taken from the body by the attentions of the soldier, there are always, in the royal chamber and the galleries adjacent, a sufficient number in waiting) and carried to the nurseries, which in a great nest may some of them be four or five feet distant in a straight line, and are consequently much farther by their winding galleries. Here, after they are hatched, the young are attended and provided with every thing necessary until they are able to shift for themselves, and take care of themselves.

TERMINALIA, a genus of plants of the class of polyandria, and order of monoecia. The male calyx is quinquipartite; there is no corolla; the stigma in ten number. The homopterous flower is the same with that of the male; there is one style; the fruit, which is a drupe or plum, is below, and shaped like a boat. There are six species.

TERMINATOR, in astronomy, a name sometimes given to the circle of illumination, from its property of determining the boundaries of light and darkness.

TENSTROEMIA, a genus of the class and order polyandria monogynia. The calyx is five-parted; the corolla one-petalled, with the five lobes on the top; berry two-celled. There are five species, trees of the East and West Indies.

TERRA PONDEROSA. See BARYTES.

TERRIL FELLUS, son of the earth, a student of the university of Oxford, formerly appointed, in public acts, to make jesting and satirical speeches against the members thereof to tax them with any growing corruptions, &c.

TERRA-PLEIN, or TERRE-PLAIN, in fortification, the top, platform, or horizontal surface, of the rampart, upon which the cannon are placed, and where the defenders perform their office. It is so called because it lies level, having only a little slope outwardly to counteract the recoil of the cannon. Its breadth is from 24 to 30 feet; being terminated by the parapet on the outer side, and inwardly by the inner talus. The cover earth, or cover, is a magnet turned of a spherical figure, and placed so that its poles, equator, &c. do exactly correspond with those of the world. It was so first called by Gilbert, as being a just representation of the great magnetic globe we inhabit. Such a terrella, it was supposed, if nicely poised, and hung in a meridian like a globe, would be turned round like the earth in 24 hours by the magnetic particles pervading it; but experience has shown that this is a mistake.

TERRIER, a book or roll, wherein the several lands, either of a private person, or of a town, college, church, &c. are described. It should contain the number of acres, and the site, boundaries, tenant's names, &c. of each piece or parcel.

TESSELATED PAVEMENTS, those of rich mosaic work, made of curious square stones, bricks, or tiles, called tesselle from their resemblance to tiles.

TEST, a vessel used in metallurgy for absorbing the sooty of metallic bodies when melted. See CUPellation, Chemistry, and Metallurgy. Some of the German vessels used in this purpose are called crucibles, a sort of friable opaline stone, called white spathe, which appears to be a species of gyp-
sum, or of the stones from which plaister of Paris is prepared. The spath is directed to be calcined with a gentle fire, in a covered vessel, till the slight cracking, which happens at first, has ceased, and the stone has fallen into part into powder, and then reduced powder, which is passed through a fine sieve, and moistened with so much of a weak solution of vitriol as is sufficient for making it hold together. Gsell, however, finds, that if the stone is of the proper kind, which can be known only by trials, calculation is not necessary. Scheffer observes, that these kind of tests are liable to solen or fals souder in the fire, and that this inconvenience may be remedied by mixing with the uncalcined stone somewhat less than equal its weight, as eight-ninths, of such as has been already used and is penetrable by the scoria of the lead, taking only that part of the old test which appears of a green-grey colour, jecting the red crust on the top. Tests or cupels made of the spath are said not to require so much caution in heating and heating them as the common ones: it appears, however, from Scheffer's account, that they are less durable and quantable than the others; though greatly superior to those of wood ashes. Vegetable ashes, which stand pretty well the testing of silver, can scarcely bear any very great quantity of gold, this metal requiring a considerably more resistance to it than bone ashes answer so effectually, and are among us so easily procurable, that it is not needful for the miner to search for any other materials; though those who work off large quantities to gain a little silver or gold contained in it, may possibly, in places remote from populous cities, avail themselves of substances similar to the spath above mentioned.

The test, for its greater security, is fixed in the mould in which it was formed; which is sometimes a shallow vessel made of crucible earth or red iron; more commonly an iron hoop, with three bars arched downwards across the bottom, about two inches deep, and of different widths, from three or four inches to fifteen or more, each material to the other; but bone-ashes answer so effectually, and are among us so easily procurable, that it is not needful for the miner to search for any other materials; though those who work off large quantities to gain a little silver or gold contained in it, may possibly, in places remote from populous cities, avail themselves of substances similar to the spath above mentioned.

The test, for its greater security, is fixed in the mould in which it was formed; which is sometimes a shallow vessel made of crucible earth or red iron; more commonly an iron hoop, with three bars arched downwards across the bottom, about two inches deep, and of different widths, from three or four inches to fifteen or more, each material to the other; but bone-ashes answer so effectually, and are among us so easily procurable, that it is not needful for the miner to search for any other materials; though those who work off large quantities to gain a little silver or gold contained in it, may possibly, in places remote from populous cities, avail themselves of substances similar to the spath above mentioned.

which cannot be allowed to constitute a part of the animal character, since in different individuals, either from age, or other circumstances, these parts are found to vary in number, there being sometimes five claws instead of four on the fore feet. The tail is about the same length with the legs, or rather shorter, with the exception of a very small wad, and terminates in a naked horny pointed tip or process.

This animal lives to a most extraordinary age; several well attested examples are described of its having considerably exceeded the period of the human race, one of the most remarkable instances is of a tortoise introduced into the archbishop's garden at Lambeth, in the time of archbishop Laud, and as near as can be collected from its story, about the year 1630, which continued to live till the year 1733, when it was supposed to have perished rather from accidental neglect on the part of the gardener, than from the mere effect of age. This tortoise has had the honour of being commemorated by Derham, and many other writers, and its shell is preserved in the library of the palace at Lambeth.

The general manners of the tortoise, in a state of domestication in this country, are very agreeably detailed by Mr. White, in his history of Selborne. "A land-tortoise," says Mr. White, "which has been kept thirty years in a little walled court, retires under-ground about the middle of November, and comes forth again about the middle of April. When it first appears in the spring, it discovers very little inclination for food, but in the height of summer it grows voracious; and then, as the summer declines, its appetite declines; so that for the last weeks in autumn it hardly eats at all. Milky plants, such as lettuce, dandelions, sow-thistles, &c. are its principal food. On the first of November 1771, I remarked that the tortoise began to dig the ground, in order to form its hybernaculum, which it had fixed on just beside a great tuft of heath flowers. It scrapes out the ground with curiously shaped claws, and this continues doers and its legs is ridiculously slow, little exceeding the hour-hand of a clock. Nothing can be more avidious than this creature, night and day it eats the earth, and continues, great body into the cavity; but as the moon of that season proved unusually warm and sunny, it was continually interrupted, and called forth by the heat in the middle of the day; and though I continued there till the thirtieth of November, yet the work remained unfinished. Harsher weather, and frosty mornings, would have quickened its operations. No part of its behaviour ever struck me more than in these two times, always expresses with regard to rain: for though it has a shell that would secure it against the wheel of a loaded cart, yet does it discover as much solicitude about rain as a lady dressed in all her best attire, shrugging away the first sprinklings, and running its head up in a corner. If attended to, it becomes an excellent weather-glass; for as sure as it walks elate, and in a manner on tip-toe, feelings with great impatience, so sure will it rain before night. It is totally a diurnal animal, and never pretends to stir after it becomes dark.

"The tortoise," adds Mr. White, "like other reptiles, has an acrid stomach, as well as tongs, and can refrain from eating, as well as breathing, for a great part of the year. It was much from its acridity, in discerning those that do it kind offices. For soon after the good old lady comes in sight who has waited on it for more than thirty years, it hobblestowards its benefactress with awkward slowness; but remained stranger. This, not only the "ox knew not her young," but the "ass his master's crib," but the most absolute and top of beings distinguishes the land that feels it, and is touched with the feelings of gratitude. This creature not only goes under the earth from the middle of November to the middle of April, but sleeps great part of the summer: for it goes to bed in the longest days at four in the afternoon, and often does not stir in the morning till late. Besides, it retires to rest for every shower, and does not move at all in wet days. When one reflects on the state of this strange being, it is a matter of wonder Providence should bestow such a seeming waste of longevity on a reptile that appears to relish it so little as to squander away more than two-thirds of its existence in a joyless slumber, and be lost to all sensation for months together in the profoundest of all slumbers! Though habituated to warm weather, he avoids the hot sun; because when once got heated, would, as the poet says of solid armour, "cold with safety." He therefore spends the more sultry hours under the umbrellas of a large cabbage-leaf, or amidst the waving forests of an alliago stigmos. But as he avoids heat in the summer, so in the decline of the year, he improves the faint autumnal beams, by getting within the reflection of a fruit-tree wall; and though he has never read that planes inclining to the horizon receive a greater share of warmth, he inclines his shell by tilting it against the wall, to collect and admit every feeble ray."

2. Testudo marginata, marginated tortoise.

The general colour of this animal is a dark or blackish bay; the middle or convex part of the pieces composing the disk, being more or less dashed or variegated, in an irregular manner, with yellow: the marginal pieces are also variegated with the same colour, which predominate in water of deep green or water without visible divisions, which are pretty distinctly striated or furrowed, and from their peculiar width or dilatation form the chief part of the specific character. The under shell is of a pale yellow colour, each division being marked on its upper commissure by a transverse blackish band, running into a pair of pointed or subtriangular processes, extending nearly to the next or inferior division. The outline of the shell, if viewed from a front angle, will be found to be much longer in proportion than that of the testudo greca, accompanied by a slight contraction or sinking in each side.

The true native country of the animal seems not very distinctly known. Mr. Schoepf is inclined to think it an American species.

3. Testudo Indica, Indian tortoise. This very large terrestrial species, which is omitted by Linnaeus in the twelfth edition of the Systema Naturae, was first described by Perrault in the History of Animals published by the Royal Academy of Paris in 1722. The specimen was taken on the coast of Coromandel, and measured four feet and a half from the tip of the nose to the tail; and its height or convexity was fourteen inches: the shell itself was three feet long and two broad, and, like every other part of the animal, was of a dull-brown colour, the shell is invested of a large and dissimilar piece, and the edge on the fore part was rather reflected, for the easier motion of the animal's head: the head was seven inches long; the mandibles serratcd, and furnished with an internal row of denticali; the fore feet are undivided, thick, and armed with five blunt claws: the hind legs were eleven inches long; the feet tetradactylus, and armed with three claws: the tail six inches thick at the base, fourteen inches long, and terminated by a horny curved process.

4. Testudo lariata, lari-tortoise. This, which is supposed by the count de Cepede to be the testudo lariata of Linnaeus, is said to be extremely common in many parts of Europe, as well as Asia, being found in India, Japan, &c. It is, in general, not more than seven or eight inches long from the tip of the nose to that of the tail, and about three or four inches in breadth: the disk consists of thirteen pieces, which are striated and slightly pointed on the margin, and along the middle range runs a longitudinal carina: the margin consists of twenty-three pieces, bordered with slight striae: the colour of the shell is blackish, more or less: deep in different specimens, and the skin itself is similar: the feet are webbed, and there are five toes before, and four behind. Like other tortoises, it sometimes utters a kind of broken or interrupted hiss. This species, according to de Cepede, is no more common than in France, and is particularly plentiful in Languedoc, and in many parts of Provence; and in a lake of about half a league wide, situated in the plain of Durance, were found such vast quantities, that the neighbouring peasantry have in a manner supported by them for more than three months together.

Though this species is aquatic, it always lays its eggs on land; digging for that purpose a hollow in the ground, and covering the hole with earth. It is of a less soft than those of the sea-tortoises or turtles, and the colour less uniform. When the young are first hatched they measure about six lines in diameter. This animal walks much quicker than the land-tortoise, especially when on even ground. It grows for a long time, and has been known to live more than twenty-four years. The taste which it has for small snails, and such kind of wingless insects as frequent the neighbourhood of the water in which it inhabits, makes it useful in a garden, which it delivers from noxious animals, without doing any mischief itself. Like other tortoises, it may be rendered domestic, and may be kept in a basin or receptacle, filled with water, so contrived on the edges as to give it room to rest upon; when it wishes to wander about for prey. The count de Cepede adds, that though useful in gardens, it is found to be a very troublesome insect in fish-ponds; attacking and destroying the fish: biting them in such a manner, that they become enfeebled by loss of blood, and then dragging them to the bottom and devouring them; having only the bones and some of the carunculated parts of the head, and sometimes the air-bladder also, which
Floating on the surface, give notice of the enemies with which the pond is infested.

5. Testudo picta, painted tortoise. The remarkable colours of the shell of this species are sufficient to distinguish it from all others: the shell is large, oval, or of a flattened or slightly convex form, and of a chestnut-brown colour, paler or darker in different individuals, and consisting, as usual, of thirteen segments, each of which is of a form approaching to square, and pretty deeply edged or bordered with paler shades: a stripe of the same colour also runs down the middle of the dorsal segments, while the marginal pieces, which are twenty-five in number, are each marked by a secalic spot of the same colour at the edge, surrounded by two, or sometimes by three yellow bands, following the direction of the first-mentioned spot, and thus forming so many semi-elliptic yellow zones or stripes on each piece. The neatness and accuracy of these, as well as of the yellow borders on the large or middle segments of the shell, vary, as may be supposed, on different individuals, and in general seem most distinctly expressed on the smallest specimens. This ceases, however, in the middle-sized tortoises: the shell measuring from four to six inches in length, or somewhat more; the head is moderately small, and covered with a smooth skin; blackish above, but yellow on the sides, and also by the ears, part, and very elegantly streaked in a longitudinal direction, with several double rows of black streaks: the legs are blackish, and marked with two longitudinal yellow stripes: the claws are sharp, and very powerful, surrounded with several lateral furrows and roughish points; the marginal pieces are twenty-three in number; the head is large, and of a brown colour, variegated on the sides with white: the legs short, sinewy, and covered with short claws, on the fore feet five distinct toes, connected to the very tips by a web, and terminated by so many sharp, crooked claws: the hind feet have only four toes, with sharp claws, and sometimes a fifth toe, resembling an appearance of a small unarmed fifth or spurious toe: the tail is short, conical, scaly, pointed, and but little exceeding the margin of the shell in length: the under shell is yellowish, spotted, and variegated with brown. See Plate Nat. Hist. fig. 399.

8. Testudo scabra, rough tortoise. The shell of the species quoted by Linnaeus in his description of T. scabra is figured in its natural size in the work of Seba, who affirms that it never grows larger than represented in his figure; measuring about two inches and a half in length, and near two inches in breadth; being of a corded figure, or somewhat elongated, the head is light reddish, pretty variegated on the head and shell with white lines and spots, in a kind of flanny or wavy pattern: the feet are marked with red specks, and each toe has five long, sharp claws: the head is very prominent, and the eyes small: down the back of the disk are represented in Seba's engraving three very conspicuous white lines or carinæ; so that the title of tri- carinata would apply to this, as well as to the species so denominated by Mr. Schoepf.

9. Testudo ferox, fierce tortoise. This remarkable species is distinguished by the unusual nature of its shell, which is hard or coriaceous, while the edges gradually degenerate into a flexible coriaceous verge: this shell is obscurely marked with five or six transverse bands, and granulated with small spots or prominences, which gradually enlarge as they approach the leathery or flexible edge: the head is rather small, and of an unusual shape, being somewhat trigonal, with the snout very much lengthened, and the eye placed at an angle, by the nostrils, and projecting much beyond the lower mandible: the neck, when retracted, appears very thick, and surrounded by many wrinkles or folds of skin; but when extended, is of very great length, so as nearly to equal that of the whole shell: the legs are short, thick, and covered with a wrinkled skin: the feet are all furnished with strong and broad webs, connecting the three last toes of each; the three first on each foot are furnished with pretty strong claws, but the remaining ones are unarmed; and besides the real or proper toes, there are two spurious or additional ones on the hind, and one on the fore feet, serving to strengthen and expand the web to a greater degree: the tail is short, pointed, and being large and round, the corners very small and round. The colour of this animal on the upper parts is a deep-brownish olive, and on the under parts white; the shell being marked beneath in a very elegant manner, with ramifications of vessels disposed upon it. The species is found in Pennsylvania, Carolina, &c. and, contrary to the nature of most others of the tribe, is possessed of very considerable vigour and swiftness of motion, springing forwards towards its assailant, when disturbed or attacked; and exhibiting great activity and alacrity. Its length is about a foot and half, or more, and its breadth about fifteen inches. It was first described by Dr. Garden, who communicated it to Mr. Pennant, by whom it was introduced into the Philosophical Transactions. Specimens examined by Dr. Garden weighed twenty-five pounds, but it is said to grow so large as to seventy pounds. The individual mentioned by Dr. Garden laid fifteen eggs during the time it was kept, which were exactly spherical, or nearly an inch in diameter, and fifteen more were found on dissection. Its flesh is said to be extremely delicate, being equal, if not superior, even to the flesh of the green turtle.

The great soft-shelled turtle, described by Mr. Bartram in his Travels, appears to be the same with this. It is said by Mr. Bartram to be of a flat form, two feet and a half long, and a foot and a half broad: the shield soft and cartilaginous on each side, and this part becomes gelatinous on being dried: the fore and hind part of the shield is beset with round horny warts or tubercles: the sternum or under shell semicartilaginous, except on the middle, where it is bony; the head large and clubbed, and the nose extended, truncated in the manner of a hog's snout: the eyes large, and seated at its base: mouth wide; the edges tuning and wrinkled, and bearded by several long processes, which are extensible at the pleasure of the animal, and give it an ugly and forbidding aspect. Mr. Bartram's figure also represents the throat and part of the neck as furnished with similar warts. Mr. Bartram adds, that it is food of the muddy parts of rivers, &c. hiding itself among the roots and leaves of water-plants, and thence springing on its prey, stretching out its neck to an incredible length, and seizing with wonderful celerity young birds, &c. &c. It is found in all the rivers, lakes, and pools, of East Florida, weighing from thirty to forty pounds. The warts or processes on each side the neck may constitute perhaps a species different from this species, green turtle; they are not to be found in that described by Dr. Garden and Mr. Pennant. See Plate Nat. Hist. fig. 399.

10. Testudo serpentina, snake tortoise. This species, first described by Linnaeus, appears to have been very obscurly known;
having been figured in no work of natural history till it was introduced into Mr. Scho-eps's publication. It is a native of North America, where it inhabits stagnant waters, growing to the weight of fifteen or twenty pounds. It feeds by preying on fish, ducklings, &c. &c. seeing its prey with great force, stretching out its neck and hissing at the same time. Whatever it seizes in its mouth it holds with great force, and will suffer itself to be raised up by a stick rather than quit its hold. The head is large, depressed, triangular, and covered with a scaly and warty skin: the orbits of the eyes are oblique; the mouth wide; the mandibles sharp; the neck covered by scaly warts, and appearing short and thick when the animal is at rest, but when in the act of sprincing on its prey, is stretched out to a third part of the length of the shell: the toes of all the feet are distinct, but connected by a web; and are five in number on the fore-feet, and four on the hind; all armed with claws longer than the toes themselves: the tail is straight, and about two-thirds the length of the shell; it is completely covered with the upper part with sharp bony scales directed backwards and gradually decreasing to the tip, while the sides and under part are covered with smaller scales: the under part of the body is covered by a loose, wrinkly, well-scaled soft scales and granules: the shell is slightly depressed, of an oval form, and consists of thirteen pieces in the disk, each of which rises behind into a kind of projection or obtuse point, and is bordered and radiated all round, and held in different directions: the general colour of the whole is a dull chesnut-brown, lighter or paler beneath.

This animal conceals itself in muddy waters in such a manner as to leave out only a part of its back, like a stone or other inanimate object, by which means it the more easily obtains its prey. Mr. Pennant, in the supplement to his Arctic Zoology, mentions this as a new species, under the name of seratus tortoises. He says, it is called by the native of China, 'Limeus is.-has been mistaken in supposing it a native of China.

Sea-tortoises, or turtles. The marine tortoises, or turtles as they are commonly called, are distinguished from those of the preceding division by their very large and long bony-scaled feet, in which are inclosed the bones of the toes; the first and second alone on each foot being furnished with visible or projecting claws, the others not appearing beyond the edge. The shell, as in the land-tortoises, consists of a strong bony covering, in which are imbedded the ribs, and which is coated externally by hard horny plates, in one or two species much thicker or stronger than those of the land-tortoises.

Testudo coriacea, coriaceous turtle. Of all the marine tortoises this appears to grow to the largest size, having been sometimes seen of the length of eight feet, and of the weight of a thousand pounds. It differs from the others in the form of its body, which is longer in proportion, and still more in its external covering, which, instead of being of a horny nature, as in others, is of a substance resembling strong leather, marked over the whole surface into small, obscurely subhexagonal and pentagonal subdivisions or lines, which do not take away from the general smoothness of the surface. Along the whole length of this covering or leathery shield run five distinct, strongly prominent, tuberculated ribs or ridges; and indeed if those parts of the body which are visible above water, are taken into account, we may say there are seven ridges on the shield. There is no under or thoracic shell, so that the animal might form a distinct genus from the rest of the tortoise tribe. The head is large, and the upper mandible prolonged at the tip in such a manner as to give the appearance of two large teeth or processes, between which, when the mouth is closed, is received the tip of the lower mandible. The fins or legs are large and long, and covered with a tough leathery skin: the tail is rather short and sharp-pointed. The general colour of the whole animal is dusky brown, paler beneath. This singular species is a native of the Mediterranean sea, and has at different periods been taken on the coasts both of France and England. In the month of August, in the year 1729, a specimen was taken about three leagues from Nantz, not far from the mouth of the Loire: it measured seven feet one inch in length, three feet seven inches in breadth, and two feet in thickness. It is said to have utter'd a hideous noise when taken, so that it might be heard to the distance of a mile. Its mouth at the same time foaming with rage, and exhaling a noisome vapour. In the year 1778, a specimen was taken on the coast of Languedoc, which measured seven feet five inches and a quarter, which was taken on the coast of Cornwall, which, according to Dr. Borlace, "measured six feet nine inches from the tip of the nose to the end of the shell; ten feet four inches from the extremes of the fore fins extended; and was judged to weigh eight hundred pounds weight." The fine specimen lately in the Leverian Museum was of similar weight, and was taken on the coast of Dorsetshire.

This species is found not only in the European sea, but in those of South America also, and occasionally appears about some of the African coasts.

According to Cepede, the coriaceous tortoise is one of those with which the Greeks were well acquainted, and he supposes it to have been the species particularly used in the construction of the ancient lyre or harp, which was at first composed by attaching the strings or wires to the shell of some marine tortoise. We may add, that the ribs or prominences on the back of the shell bear an obscure resemblance to the strings of a harp, and may have suggested the name of luth or lyre, by which it is called among the French, exclusive of the use to which the shell was antiently applied.

The coriaceous tortoise, says Mr. Pennant, is reputed to be extremely fat, but the flesh coarse and bad: the Carthagians, however, will eat no other species.

It may be added, that the small sea-tortoise described by Mr. Pennant, in the Philo-losophical Transactions for the year 1771, is evidently no other than the young of this animal. See Plate Nat. Hist. fig. 305.

2. Testudo mydas. The green turtle, so named, not on account of its being externally green, but from the green tinge which its fat frequently exhibits when the animal is taken in its highest state of perfection, may be considered as one of the largest of this genus, often measuring above five feet in length, and weighing more than five or six hundred pounds. It frequents in a somewhat heart-shaped form, or pointed at the extremity, and consists of thirteen dorsal segments or divisions surrounded by twenty-five marginal pieces. Its colour is a dull pale-brown, more or less variegated with deeper undulations, but not exhibiting those strong and beautiful colours which so peculiarly distinguish that of the T. imbricata, or hawk's-bill turtle, which affords the tortoise-shell used for ornamental purposes in various manufactories, having neither sufficient strength nor beauty: but so much is the flesh esteemed, that the inhabitants of the West Indian islands have long considered it as one of the most excellent articles of food, and have gradually succeed- ed in introducing a similar taste among some of the European nations. In our own country in particular it is in the highest estimation, and is regularly imported in considerable quantity from the Metropolis.

The introduction of the green turtle as an article of luxury into England is of no distant date, and perhaps can hardly be traced much farther than about fifty or sixty years backward. Formerly the nature of the sea-tortoises understood by the Europeans before that period, if the different kinds were in general confounded by navigators, who-accounts relative to their charac-teristics, a food vain to the species which they happened to take for that pur- pose; some insisting that the turtle was a coarse and unpalatable diet, while others considered it as of the highest degree of excel- lence. "Of the sea-turtles," says Catesby, "the most in request is the green turtle, which is esteemed a most wholesome and delicious food. It receives its name from the fat, which is of a green colour. Sir Hans Sloane informs us, in his History of Jamaica, that forty sloops are employed by the inhabitants of Port Royal, in Jamaica, for the catching them. The markets are there supplied with turtle in great quantities. The Bahama-rians carry many of them to Carolina, where they turn to good account; not because that plentiful country wants provisions, but they are esteemed there for their flesh, and for the delicacy of their flesh. They feed on a kind of grass, growing at the bottom of the sea, commonly called turtle-grass. The inhabit-ants of the Bahama Islands, by often practice, and very expert at catching turtles, particu-larly the green turle. In April they go, in little boats, to Cuba and other neighbour- ing islands, where, in the evening, especially in moonlight nights, they watch the going and returning of the turtle to and from their nests, at which time they turn them on their backs, where they leave them, and proceed on, turn-ing all they meet; for they cannot get on their feet again when once turned. Some are large that three men to turn over them. The way by which the turtle, which are most commonly taken at the Bahama is-lands is by striking them with a small iron peg of two inches long, put in a socket, at the end of a staff of twelve feet long. Two men generally set out for this work in a little light boat or canoe, one to row gently and steer the boat, while the other stands at the
head with his striker. The turtle is sometimes discovered by their swimming with their head and back out of the water, but they are often discovered lying at the bottom, a fathom or more deep. If a turtle perceives he is discovered, he starts up to make his escape: the men in the boat pursuing him, endeavour to keep sight of him, and recover again by the turtle putting his nose out of the water to breathe: thus they pursue him, one paddling or rowing, while the other stands ready with his striker. It is sometimes half an hour before he is then beaten to one at once to the bottom, which gives them an opportunity of striking him: which is by piercing him with an iron peg, which slips out of the socket, but is fastened with a string to the pole. If he is spent and tired by being long pursued, he tamely submits, when struck, to be taken into the boat or hauled ashore. There are men who by diving will get on their backs, and by pressing down their hind parts, and raising the fore part of their force, bring them to the top of the water, while another slips a noose about their necks.

Though the green turtle is a native of the West Indian seas, yet it is sometimes driven by storms on shore, and residence, and instances have occurred in which it has been taken on the coasts of Europe. An occurrence of this kind is said by the count de Cepede to have happened in France, a turtle having been taken at Dieppe in the year 1732, which weighed between eight and nine hundred pounds, and was almost six feet in length, and four wide. It may, however, be doubted whether this animal was not rather a caretta or loggerhead, than a green turtle. Another, of still larger size, is also said to have been taken on the coast of France, about two years afterwards.

The sea-tortoises, or turtles in general," says Catesby, "never go on shore but to lay their eggs, which they do in April: they then crawl up on the sea above the flowing of high water, and dig a hole above two feet deep in the sand, into which they drop in one night above a hundred eggs, at which time they are called their nature's oysters; they regard none that approach them; but will drop their eggs into a hat, if held under them; but if they are disturbed before they begin to lay, they will forsake the place, and seek another. They lay their eggs at three, and sometimes at four different times; there being fourteen days between every time; so that they hatch and creep from their holes into the sea at different times. When they have laid their complement of eggs, they fill all the hole with sand, and leave them to be hatched by the heat of the sun, which is usually performed in about three weeks." It may be proper to add, that the eggs are about the size of tennis-balls round, and the shell thicker than an inch, with a smooth parchment-like skin. See Plate Nat. Hist. fig. 309.

3. Testudo imbricata, the hawks-bill turtle. The testudo imbricata is so named from the peculiar disposition of its scales or lamina, which commonly lap over each other at their extremities in the manner of tiles on the roof of a building. The outline of the shell, viewed from above, is more heart-shaped than in other sea-tortoises, and terminates more acutely: each of the middle row of scales on the back is also of a sharpened form at the tip, more especially in the young or half-grown animal, and has a ridge or caine down the middle of each, and is smaller in proportion than in other turtles; the neck longer; and the beak narrower, sharper, and more curved, so as to give no incomparable resemblance to the bill of a hawk, from which circumstance the animal derives its common or popular name of the hawks-bill turtle. The fore legs are longer than in the rest of the tribe, and it is said that when turned or laid on its back, the animal is enabled by their as- tounding strength, to bear up in a manner as to recover its former situation, which no other turtle can do. In old specimens the neatness of the shell, and the well-defined outline of the scales, are occasionally impaired, and this seems to be one principal reason of its having been sometimes confounded with the carapace of the hawk. This bill turtle is a native of the Asiatic and American seas, and is sometimes, though less frequently, found in the Mediterranean. Its general length seems to be about three feet, from the tip of the bill to the end of the shell; but it has been known to measure five feet in length, and to weigh five or six hundred pounds. In the Indian ocean in particular, specimens are said to have occurred of prodigious magnitude.

The shell of this animal was anciently used for a shield, and still serves for that purpose among barbarous nations. The flesh is in estimation as a food; the lamellae or plates of the shell, which are far stronger, thicker, and clearer than in any other kind, constitute the sole value of the animal, and affording the substance particularly known by the name of tortoise-shell: they are semitransparent, and most elegantly variegated with whitish, yellowish, reddish, and dark-brown chords and undulations, so as to constitute, when properly prepared and polished, one of the most elegant articles for ornamental purposes.

See TECTUS: SHELL.

The natural or general number of the dorsal pieces is thirteen; the marginal row consisting of twenty-five smaller pieces. This external coating is raised or separated from the bone on which it covers, by placing fire beneath the shell; the heat causes the plates to start, so as to be easily detached from the bone. These plates vary in thickness, according to the age and size of the animal, and measure from one eighth to one quarter of an inch in thickness. A large turtle is said to afford about eight pounds of tortoise-shell.

In order to bring tortoise-shell into the particular form required on the part of the artist, it is steeped in boiling water, till it has acquired a proper degree of softness, and immediately afterwards committed to the pressure of a strong metallic mould of the figure required; and where it is necessary that the pieces should be joined and imbedded in a surface of considerable extent, the edges of the respective pieces are first scraped or thinned, and being laid over each other during their heated state, are committed to a strong press, by which means they are effectually joined or agglutinated. These are the methods also by which the various ornaments of gold, silver, &c. are occasionally affixed to the tortoise-shell.

The Greeks and Romans appear to have been peculiarly partial to this elegant ornamental article, with which it was customary to decorate the doors and pillars of their houses, their beds, &c. &c. In the reign of Augustus this species of luxury seems to have been at its height in Rome.

"The Egyptians," says Mr. Bruce, in the supplement to his Travels, "dealt very largely with the Romans in this elegant article of commerce. Pliny tells us the cutting them for fingering or inlaying was first practised by Carvilius Pollio, from which we should presume, that the Romans were ignorant of the art of separating the lamina by fire placed in the shell, which, as he says, they did not know out: for these scales, though they appear perfectly distinct and separate, do yet adhere, and often break than split, where the mark of separation may be seen distinctly. Mar-
TETRAEDRON, or TETRAEDRON, in geometry, is one of the five finite or regular bodies or solids, comprised under four equilateral and equal triangles. Or it is a triangular pyramid of four equal and equilateral faces.

In the description of the tetrahedron it is determined that the side of a tetrahedron is to the diameter of its circumscribing sphere, as $\sqrt{2}/2$ to $\sqrt{3}$; consequently they are incommensurable.

If a denotes the linear edge or side of a tetrahedron, $b$ its whole superficies, $c$ its solidity, $r$ the radius of its inscribed sphere, and $R$ the radius of its circumscribing sphere; then there is a general relation among all these is expressed by the following equations.

\[
a = 2\sqrt{2}/3 \approx 1.15; \quad b = 2\sqrt{3}/3 \approx 1.23; \quad c = 3\sqrt{3}/2 \approx 2.69; \quad R = \frac{2}{3}; \quad r = \frac{2\sqrt{3}}{3}.
\]

TETRAMORNIA (toward four, and power), four powers; the name of the 15th class in Limnæus's sexual system. See Botany.

TETRAO, of this genus the following species are found in Britain: 1. The uncorus, or lack of the wood, inhabits woody and mountainous countries; in particular, forests of pines, birch-trees, and junipers; feeding on the fruits of the former, and berries of the latter; the first often infests the flesh with such a taste as to render it scarcely edible. In the spring it calls the females to its haunts with a loud and shrill voice; and is at that time so very inoffensive to its safety, as to be very easily shot. It stands perched on a tree, and descends to the females on their first appearance. They lay from eight to sixteen eggs; eight at the first, and more as they advance in age.

This bird is common to Scandinavia, Germany, France, and several parts of the Alps. It is found in no other part of Great Britain than the Highlands of Scotland, north of Inverness; and is very rare even in those parts.

The length of the male is two feet nine inches; its weight sometimes fourteen pounds.

The female is much less, the length being only two feet six inches. The sexes differ also greatly in colours. The head of the female is of a pale yellow; the head, neck, and back, are elegantly marked, slender lines of grey and black running transversely. The upper part of the breast is of a rich glossy green; the rest of the breast and belly black, mixed with some white feathers; the sides are marked like the neck; the coverts of the wings crossed with undulated lines of black and reddish brown; the exterior webs of the greater quill-feathers are black; the tail consists of eighteen feathers, the middle of which is the longest; these are black, marked on each side with a few white spots. The legs are strong and covered with brown feathers; the edges of the toes are black. Of the female, the bill is dusky; the throat red; the head, neck, and back, are masked with transverse bars of red and black; the breast has some white spots on it, and the lower part is of a plain orange-colour; the head and neck is larded with pale-orange and black; the tips of the feathers are white. The tail is of a deep rust-colour, barred with black, tipped with white, and consists of sixteen feathers.

2. The tetric, black grouse, or black-cock, like the former species, is fond of woody and mountainous situations; feeding on the Vaccinium, and other mountain-fruits, and in the winter on the tops of the heather. In the summer they frequently descend from the hills to feed on corn. They never pair; but in the spring the male gets upon some eminence, crows and claps his wings; on which signal all the females within hearing resort to him. The hen lays seldom more than five or seven eggs. When the female is obliged, during the time of incubation, to leave her eggs in quest of food, she covers them up so artfully with only twenty-four hours above; but it is very difficult to discover them. On the occasion she is extremely tame and tranquil, however wild and timorous at other times. She often keeps

In the antient music, all the primitive or chief divisions were confined to four chords; so that the great scale consisted of repetitions, and all the upper tetrachords were considered only as repetitions of the first or lowest.

TETRADIAPASON, the Greek appellation of the quadruple octave, which we also call the 29th; in systems of the antients not extending to this interval, they only knew it in imagination, or by name.

TETRADYNAHIA (towards four, and power), four powers; the name of the 15th class in Limnæus's sexual system. See Botany.
her next though strangers attempt to drag away. As soon as the young ones are chased, they are seen running with extreme fertility after the mother, though sometimes they are not entirely disgorged from the egg. The hen leads them forwards for the first time into heath, and when they see them alight and alight on the wild mountain-berries, which, while young, are their own food. As they lower their appetites grow stronger, and they feed upon the tops of heath and heath cones of about a month old; at the end of which the young males fly for her, and keep in great harmony together till the beginning of spring. At season they begin to consider each other's possible game-cocks, that time is so intimate to their own dignity, that it often happens that two or three are killed at a shot.

An old black cock is in length twenty-two inches, and weighs near four pounds. The bill is dusky; and the plumage of the whole body black, crossed over the neck and rump with a shining blue. The coverts of the wings are of a dusky brown; the inner coverts white; the thighs and legs are covered with dark-brown feathers; the toes resemble those of the former species. The female coverts only two pounds, and its length is one of six inches. The head and neck are marked with alternate bars of dull red and black; the breast with dusky black and white; and the last pre-coccyx. The back, coverts of the wings, and tail, are of the same colours as the neck, but the red is deeper. It is slightly forked. The feathers under the tail are white, marked with a few bars of black and white. This bird is the largest in the same late in the summer. It lays from six to eight eggs, of a dull yellowish-white colour, marked with numbers of very small ferruginous specks; and towards the smaller end with some blotches of the same hue. See Nat. Hist. fig. 400.

3. The scoticus, red game, or moor-fowl, peculiar to the British islands. The male has about nineteen inches; and is in body 134 inches. The plumage on the head is of a light tawny red; each feather is marked with dusky bars of the middle and black. The back and scapular feathers are a deep red; and on the middle of each other is a large black spot; the breast and belly are of a dull purplish brown, crossed in its numerous narrow dusky lines; the legs and feet are clothed to the claws with sick white feathers. The claws are sharp, very broad and strong. The female has only fifteen inches. The colours in general are duller than those of the male. These birds pair in the spring, and lay from six to ten eggs. The young brood follow the adult in the whole summer; in the winter they are in flocks of forty or fifty, and become remarkably shy and wild; they always keep on the tops of the hills, are scarcely ever found on the sides, and never descends into the valleys. Their food is the mountain-berries and tops of the heath.

4. The lagopus, white game, or ptarmigan, is fifteen inches in length, and weighs nineteen ounces. Its plumage is of a pale brown or ash-colour, elegantly crossed or mottled with small dusky spots and minute bars; the head and neck with broad bars of black, rust-colour, and white: the belly and wings are white, but the shafts of the greater quill feather black; in the middle, the rear feathers are grey, blue, and white, and the neck, where there is a mixture of red, with a white bar. The females and young birds have a great deal of rust-colour in them. The tail consists of sixteen feathers; the two middle of which are ash-coloured, marked with black, and tipped with white; the two next black, slightly marked with white at their ends, the rest wholly black: the feathers beneath the tail are white, and almost entirely cover it.

Ptarmigans are found in this kingdom only on the summit of the highest hills of the Highlands of Scotland, of the Hebrides and Orkneys; and a few still inhabit the lofty hills of Kreswick in Cornwall, as well as the mountains of Wales. They live amid the rocks, perching on the grey stones, the general colour of the strata in these exposed situations. They are very likely birds; so tame as to bear driving like poultry; and, if provoked to rise, take very short flights, making a great circuit like pigeons. Like the grouse, they keep in small packs; but never, like those birds, take shelter in the heath, but beneath loose stones. To the taste they scarcely differ from a grouse.

II. Perdix, comprehends both the partridge and quail.

In England, the partridge is a favourite delicacy at the tables of the rich; and the desire of keeping it to themselves has induced them to make laws for its preservation, no way harmonising with the general spirit of English legislation. The partridge seems to be a bird well known over all the old continent. Their feathers resemble those of the game-cocks in general; but their cunning and instinct seem superior to those of the larger kinds. Perhaps, as they live in the more neighbourly of their enemies, they have more frequent occasions to put their ingenuity in practice, and learn by habit the means of evasion or safety. Whenever therefore a dog or other formidable animal approaches their nest, the female very well knows how to be incapable of flying, just hops up, and then falls down before him, but never goes off so far as to discourage her pursuer. At length, when she has drawn him entirely away from her secret treasure, she at once takes wing, and fairly leaves him to gaze after her despair. After the danger is over, and the dog withdrawn, she then calls her young, who assemble at once at her cry; and follow where she leads them. There are generally from ten to fifteen in a covey; and, if un molested, they live from fifteen to seventeen years.

2. The coturnix, or common quail, is not above half the size of the partridge. The feathers of the head are black, edged with rusty brown: the breast is of a pale yellowish red, spotted with black; the feathers on the back are marked, with lines of pale yellow, and the legs are of a pale hue. Except in the colours thus described, and the size, it ever resembles a partridge in shape, and, except that it is a bird of passage, it is like all others of the poultry kind in its habits and nature.

The quail seems to spread entirely throughout the old world, but does not inhabit the mountains. It is proposed to shift its quarters according to the season, coming northward in spring, and departing south in autumn, and in vast flocks, like other migrating birds. I twice in a year it comes in such vast quantities as to capri, that the bishop of the island draws the cries of its revenue from them; hence he is called the quail-bishop. But this does not stand alone; almost all the islands in the Archipelago, on the opposite coasts, are at times covered with these birds, and some of them occurring in this circumstance. Onto the west coast of the kingdom of Naples, within the space of four or five miles, a hundred thousand have been reported to be seen in a day, which have been sold for eight livres per hundred to the dealer for sale them to Rome. Great quantities also sometimes alight in spring on the coasts of Provence, especially in the diocese of the bishop of Frejus, which is near the sea, and appear at their first landing, as if they were afraid that they are often taken by the hand.

With us they may be said not to be plenty at any time. They breed with us, and the major part migrate south in autumn; the rest only shift their quarters, as they have been met with on the coasts of Essex, and in Hampshire, in the winter season, retiring thence in October.

It feeds like the partridge, and, like that bird, makes no nest, except a few dry leaves or sticks scraped together may be called so; and sometimes a hollow on the bare earth suffices. In this the female lays her eggs to the number of six or seven, of a whitish colour, marked with irregular rust-coloured spots. Its song is very original. It is never long as is hatched, like young partridges. They have but one brood in a year.

Quail-fighting was a favourite amusement among the Athenians. They abstained from the flesh of this bird, deeming it unholy; some, as supposing that it fed upon the white hellebore; but they reared great numbers of them for the pleasure of seeing them fight; and staked sums of money, as we do with cock, upon the success of the combat. Fashion, however, has at present changed with regard to this bird: we take no pleasure in its coigne, but its flesh is considered as a very great delicacy. Quails are easily caught by a call: the Fowler early in the morning having spread his net, and go out of it among the corn; he then imitates the voice of the female with his quail-pipe, which the cock hearing, approaches with the utmost assiduity; when he has got under the net, the Fowler then discovers himself, and terrifies the quail, who attempting to get away, entangles himself in the more in the net, and is taken.

TETRODON, a genus of fishes of the order Nines. The generic character is, jaws bony, divided at the tip; body roughened beneath; ventral has teeth.
1. Tetradon lapidaceus, bare tetradon. The fishes of this genus, of which there are
14 species, like all the others, have the power of inflating their body at pleasure, by means of
an internal membrane for that purpose, and during the time of inflation the small
spines disappear over their sides and abdomen are erected in such a manner as to operate as
a defence against their enemies: they are chiefly natives of the tropical seas, though
sometimes seen in the higher northern and southern latitudes, and are supposed to live
principally on the crustaceous and testaceous animals.

The present species grows to the length of
about twelve inches, and is of a thick form in
front, the hinder parts tapering suddenly
toward the base, the colour being a fresh
pink above, and whitish with a slight silvery
cast beneath. The present species has branches
of the Northern seas, sometimes seen
presented with numerous small spines. To the
abdomen, with numerous, longitudinal,
ventral, deep-brown streaks; fins and tail as in
the preceding species. The native of the Medi-
terranean and American seas, sometimes
found in the river Nile, where Hassequist
was assured by the fishermen that on being
taken the hands were stung in the same manner
as with nettles.

2. Tetradon testudinus, tortoise-shell te-
tradon. Length two feet; shape lengthen-
ed; colour rufous-brown above, marked by
circular round, pale-blue spots; beneath
shiny or ash-coloured, beautifully varied by
longitudinal and transverse black streaks; fins and tail
bright yellow; the whole abdomen is
dressed with numerous small spines, which,
when the animal is in a quiet state, are im-
bedded in so many corresponding cavities in the
abdomen; but when elevated when the slightest
alarm, distends its body. Native of the
Indian seas. The Linnaean name of this fish
is supposed to have been given from its
tortoise-like bulk, but perhaps, with more propriety,
from its variegated skin.

3. Tetradon ocellatus, ocellated tetradon.
Length six or eight inches; shape thick,
wide, contracting suddenly towards the tail:
mouth slightly produced: colour deep-green
above, a yellow tint on sides; eyes raised,
position on the sides, and abdomen, which are white.
Native of the Indian seas, and sometimes of the
adjacent rivers, particularly those of China
and Japan. It is of an extremely poisonous
nature, it eaten without the greatest care it
properly cleaning it before dressing, and is
said sometimes to have proved fatal in the
short space of two hours. The symptoms,
according to Rumphius, may be curable by the
treatment of the administration of a vegetable which
he calls rex amaronis. The emperor of Ja-
pan prohibits his soldiers, under very severe
penalties, from eating this fish: the rest of his
subjects may, as Mr. Pennant observes, run
the risk of being poisoned with impunity.

TEUCRUM, germander, a genus of
plants of the class dianemum, and order
gynopasminata; and in the natural system ran-
ging under the 42d order, verticillata. The
corolla has the upper lip divided into two
parts beyond the base, and divericated where
the stamina issue out. There are 69 species,
of which the scorodonia, scormium, and cha-
maidrys, are species of common occurrence. 1. The
scordonia, wood sage, or germander, is dis-
tinguished by leaves which are heart-shaped,
 serrated, and petiolated; by racemi, which are erect
and expanded in one row; and by an erect stem.
The flowers are straw-coloured, and the filaments red. 'The plant has a bit-
ter taste, and smells like hops, with a little mixture of garlic. It is used in brewing in
the isle of Jersey instead of hops. 2. The scor- domium, or common water-germander, has
creeping perennial roots, sending up many square,
procumbent, or trailing stalks, branch-
ing diffusely, and small reddish flowers. This
plant was formerly considered as medicinal,
but has now fallen into disuse. It grows na-
aturally in marshy places, in the isle of Ely
and other parts of England, and most parts of
Europe; and is sometimes admitted into gar-
dens, in many countries, for variety, and as
an ornamental plant. S. The chamaedrys, or small-
ner creeping germander, has reddish flowers,
growing almost in a verticillus, or whorls,
round the stalk, three on each peduncle: ap-
pearing in June and July. There are also some
species, ornamental as greenhouse
plants.

THALIA, a genus of plants of the class monandria, and order
polygynia; and in the natural system ranging under the 8th or
decasminata. The corolla is petunia-like
and undulated; and the drupe has a
smooth kernel. There are two species;
the genculata and canaxifrons.

H Alyrtrum, meadows rue, a genus of plants
of the class polyandria, and order
polygynia; and in the natural system ranging under the 29th order.
There is now no calyx; the petals are four or five in num-
ber, and the seeds are naked and without a
tail. There are 22 species; three of which are indigenous, the flavum, minus, and alpin-
um. The flavum or meadow, rue, has a leafy furrowed stalk, and a man-
fold erect panicule. It has commonly 24 sta-
mina, and from ten to sixteen pistils. The
root and leaves of the plant dye a yellow col-
our, and cattle are fond of it. It grows on
the banks of some rivers. 2. The minus, or
small meadow-rue, has sepals and leaves,
and a branching flowers. This plant is frequent
in sandy soils and mountainous pastures.

The alpinum, or alpine meadow-rue, has
evry simple stalk, and almost naked; and
racemus simple and terminal. It is frequent on
the sides of rivulets.

THALIFITE, a stone found in the
isles of mountains in Denmark, and
Chamouni, in the Alps. It is sometimes
amorphous, and sometimes crystallized. The
primitive form of its crystals is a rectangular
prism, whose bases are rhombi with angles of
96.5 degrees. The most usual variety is an
elongated four-sided prism (often flattened),
terminated by four-sided inco-
plete pyramids; sometimes it occurs in regular
six-sided prisms. The crystals are often very
shaped.

Its texture appears fibrous. Lustr 2.
Glassy. Causes single refraction. Britti
Specific gravity 3.42 to 3.46. Colour dark
green. Powder white or yellowish green and
feels dry. It does not become electric by
rubbing, but by the blowpipe, frotts, and
melts into a black slag. With borax melts
into a green bead.

A specimen of thalifite, analysed by Mr.
Descôteil, contained

THASPIA, the deadly carrot, a genus of
plants of the class pentandria, and order di-
and in the natural system ranging under the 42d order, umbelliferae. The plant is of noble growth, and the fruits are very beautiful. There are six species; the villous, sativa, asclepium, giganica, trifolita, and polygami. The roots of the latter were formerly ordered in medicine, but are now entirely disused. It is cultivated along with extreme violence in both uplands and downwarlds.

**THEA.** The tea-tree, in botany, a genus of the class and order polygonaceae, monogynia. The corolla is six or nine-petalled; the calyx five or six-leaved; the capsule triloculcus. There are three species, which are the most principal varieties. The viridis or green, and the bohea, which again admit of various subdivisions or varieties. There is, however, much uncertainty on this point. The country of which the tea plant is a native is hidden from the exploring eye of the philosopher; it is jealous of Europeans, and seldom gives them an opportunity of studying its productions. The tea plant is a native of Japan, China, and Tartary, and has not, as far as we can learn, been introduced growing spontaneously in any other part of the world. Sir Charles Thunberg, one of the most distinguished pupils of Linnaeus, who resided sixteen months in Batavia and Japan, has given a full description of the tea plant, and having classified it in the same manner as his master, says expressly that it has only one style. Several of the British botanists, on the other hand, refer it to the order of trigniae; declaring their authority from a plant in the duke of Northumberland's garden at Sion-house, which had three styles.

Linnaeus says that there are two species of the tea plant; the bohea, the corolla of which has six petals; and the viridis, or green tea, which has nine petals. Thunberg makes only one species, the bohea, consisting of two varieties: the one with broad and the other with narrow leaves. This botanist's authority is decisive respecting the Japanese tea plants; but as this subject has not yet been explored, we cannot determine what number of species there are in that country. The tea-tree, however, is now common in the botanical gardens in this country, and part of their prize plants, and there are several varieties, or, at least, permanent varieties of it: one with a much longer leaf than the other, which our gardeners call the green tea; and the other with shorter leaves, which they call the bohea. The greatest is by much the hardest plant, and with very little protection will bear the rigours of our winters. Messrs. Loddridges, of Hackney, have now several large plants of it in the open ground, which they only cover with mats in hard frost. They are chiefly propagated in this country by layers. See Plate Nat. Hist. fig. 400.

This plant delights in valleys, and is frequent on the sloping sides of mountains and the banks of rivers. In its native country it enjoys a southern exposure. It flourishes in the northern latitudes of Pekin as well as round Canton; but attains the greatest perfection in the mild temperate regions of Naskit. It is said only to be found between the 45th and 44th degree of north latitude. In Japan it is planted round the borders of fields, without regard to the soil; but as it is an important article of commerce with the Chinese, whole fields are sown with it, and it is by them cultivated with care. Thenob Rochen says, it grows equally well in a poor as in a rich soil; but that there are certain places where it is of a better quality. The tea which grows in rocky ground is superior to that which grows in a light soil; and the worst kind is that which is produced in the plains. It is propagated by seeds; from six to twelve are put into a hole about five inches deep, at certain distances from each other. The reason why so many seeds are sown in the same hole is said to be, that only one plant will vegetate. Sometimes this plant, being thus sown, grows with no other care. Some, however, manure the land, and remove the weeds; for the Chinese are as fond of good tea, and take as much pains to procure it of an excellent quality, as the Europeans do to procure excellent wine. The leaves are not fit for being plucked till the shrub is of three years' growth. In seven years it rises to a man's height; but as it then bears but few leaves, it is cut down to the stem, in this production a new crop of fresh leaves about the following summer, every one of which bears nearly as many leaves as a whole shrub. Sometimes the plants are not cut down till they are ten years old. We are informed by Kämpfer, that some seasons in which the leaves are collected in the islands of Japan, from which the tea derives different degrees of perfection.

The first gathering commences at the end of February or beginning of March. The leaves are then small, tender, and unfolded, and not above three or four days old: these are called fitch-tsiaa, or "tea in powder," because it is pulverised; it is also called imperial tea, being generally reserved for the court and people of rank; and sometimes also it is named bloom tea. It is sold in China for 20d. or 2s. per pound. The labourers employed in collecting it do not pull the leaves by handfuls, but pick them up one by one, and take every precaution that they may not break them. However long and tedious this labour may appear, they gather from four to ten or fifteen pounds a day.

The second crop is gathered about the end of March or beginning of April, just after this season's leaves have attained their full growth, and the rest are not above half their size. This difference does not, however, prevent them from being all gathered indiscriminately. They are afterwards picked and assorted into different parcels, according to their age and size. The youngest, which are carefully separated from the rest, are often sold for leaves of the first crops, or for imperial tea. Tea gathered at this season is called tea-tsinia, or "Chinese tea," because the people of Japan infuse it, and drink it after the Chinese manner.

The third crop is gathered in the end of May, or in the month of June. The leaves are then very numerous and thick, and have the appearance of a young shoot. This kind of tea, which is called ben-tsiaa, is the coarsest of all, and is reserved for the common people. Some of the Japanese collect their tea only at two seasons of the year; and the second, as has already mentioned: others confine themselves to one general gathering of their crop, towards the month of June; however, they always form afterwards different assortments of their leaves.

An infusion of tea is the common drink of the Chinese; and indeed, when we consider one circumstance in their situation, we must acknowledge that Providence has displayed much goodness in scattering this plant with so much profusion in the empire of China. The water is said to be unwholesome, and would therefore, perhaps, without some corrective, be unfit for the purposes of life. The Chinese pour boiling water over their tea, and leave it to infuse, as we do in Europe, but they use it in mixture and even without sugar. The people of Japan reduce theirs to a fine powder, which, they dilute with warm water until it has acquired the consistence of thin soup. Their manner of serving tea is as follows: They place before the company the tea-equipage, and the box in which this powder is contained; they fill the cups with warm water, and taking from the box as much powder as the point of a knife can contain, throw it into each of the cups, and stir it with a tooth-pick until the liquor begins to foam; it is then presented to the company, who sip it while it is warm. According to Du Halde, this mode has been peculiar to China, and is also used in some of the provinces of China.

The first European writer who mentions tea is Giovanni Botero, an eminent Italian author, who published a treatise about the year 1590, on the causes of the magnificence and greatness of cities. He does not indeed mention its name, but describes it in such a manner that it is impossible to mistake it. "The Chinese (says he) have a herb out of which they press a delicate juice, which serves them for drink instead of wine; it also preserves their health, and frees them from all those evils which the immoderate use of wine produces among us."

Tea was introduced into Europe in the year 1610 by the Dutch East India company. It is generally said, that it was first imported from Holland into England, in 1666, by the lords Arlington and Ossory, who brought it into fashion among people of quality. But it was used in coffee-houses before this period, as appears from an act of parliament in 1660, in which a duty of 8d. was laid on every gallon of the infusion sold in these places. In 1666 it was sold in London for 6s. per pound, though it did not cost more than 2s. or 3s. 4d. at Batavia. It continued at this price till 1707. In 1715 green tea began to be used; and as great quantities were then imported, the price was lessened, and the practice of drinking tea descended to the lower ranks. In 1720 the French began to send it to us by a clandestine cominerce. Since that period the demand has been increasing yearly, and it has become almost a necessary of life in several parts of Europe, and among the lowest as well as the highest ranks.

The following table will give an idea of the quantity of tea imported annually into Great Britain and Ireland since 1717:

Besides those quantities imported into Britain and Ireland, much has been brought to Europe by other nations.
THE whole tea imported into Europe from China amounted to 17 million pounds; in 1785 it was computed to be about 19 million pounds.

In this country teas are generally divided into three kinds of green, and five of bohea: the former are 1. Imperial or bloom tea, with a large loose leaf, light-green colour, and a faint delicate smell. 2. Hyson, so called from the name of the merchant who first imported it: the leaves of which are closely curled and small, of a green colour, verging to a blue: 3. Single tea, from the name of the place where it is cultivated. 4. Congou, which imparts a yellow-green colour by infusion. 2. Canmo, so called from the place where it is made; a fragrant tea, with a violet smell; its infusion pale. 3. Congo, which has a larger leaf than the preceding, and its infusion somewhat deeper, resembling common bohea in the colour of the leaf. 4. Pekoe tea; this is known by the appearance of small white down mixed with it. 5. Common bohea, whose leaf is darker and one colour. There are other varieties, particularly a kind of green tea, done up in roundish balls, called gunpowder tea.

THEATINES, a religious order in the Roman church, so called from their principal founder John Picon, bishop of Theate or Chieti, in the kingdom of Naples, and afterwards pope, under the name of Paul IV.

THEFT, in law, an unlawful felonious taking away another man's moveable and personal goods, against the owner's will, with intent to steal them. It is divided into theft or larceny, properly so called, and petty theft, or petty larceny; the former wherein is of goods above the value of 12d. and is deemed felony; the other, which is of goods under that value, is not felony. See the articles Felony and Larceny.

THEFTBOTE, the receiving a man's goods again from a thief, or other amends, by way of composition, and to prevent prosecution, that the felon may escape unpunished; the punishment whereof is fine and imprisonment.

THELIGONUM, a genus of plants of the class monoeccia, and order polyanthria; and in the natural system ranging under the 33d order, scabridae. The male calyx is bith; there is no corolla; the stamens are generally 12. The female calyx is also bith; there is no corolla; only one pistil; the capsule is coriaceous unilocular, and monospermous. There is only one species, the cynoaranea, which is indigenous in the south of Europe.

THEOBROMA, a genus of plants of the class polypodiophyta, and order decandria; and in the natural system ranging under the 37th order, columnifera. The calyx is triphyllous, and there are five in number, are vaulted and two-horned; the nectarium is pentaphyllous and regular; the stamina grow from the nectarium, each having five anthers, see Plate Nat. Hist. fig. 492. There is one species:

The cacao, or chocolate-tree, which we shall describe in the words of Dr. Wright: "In all the French and Spanish islands and settlements in the warmer parts of America, the chocolate-tree is carefully cultivated. This was formerly the case also in Jamaica but at present we have only a few straggling trees left as monuments of our indolence and bad policy. There are delightful walks in shady places and deep valleys. It is seldom above 20 feet high. The leaves are oblong, large, and pointed. The flowers spring from the trunk and large branches; they are small, and pale red. The pods are oval and pointed. The seeds or nuts are numerous, and are curiously stowed in a white pithy substance. The cocoa-nuts being gently parched in an iron pot over the fire, the external covering separates easily, and is levigated on a smooth stone; a little anacto is added, and with a few drops of water is reduced to a mass, and formed into rolls of one pound each. This simple preparation of chocolate is the most natural, and the best. It is in daily use in most families in Jamaica, and seems well adapted for rearing of children."

THEODOLITE, a mathematical instrument much used in surveying, for the taking of angles, distances, &c.

THEOREM, a proposition which terminates in tautology, and which considers the properties of things already made or done. Or a theorem is a speculative proposition, deduced from several definitions compared together. Thus in triangle is compared with a parallelogram standing on the same base, and of the same altitude; and party from their immediate definitions, and partly from other of their properties already determined, it is inferred that the parallelogram is double the triangle; that proposition is a theorem.

Theorem stands contrasting from problem, which denotes something to be done or constructed, as a theorem proposes something to be proved or demonstrated.

There are two things to be chiefly regarded in every theorem, viz., the proposition and the demonstration. In the first is expressed what is to be demonstrated, in certain ideas, and what is to be demonstrated. In the latter, the reasons are laid down by which the understanding comes to conceive that it does or does not agree to it.

Theorems are various kinds: an Universal theorem, is that which extends to any quantity without restriction, universally, as this, that the rectangle or product of the sum and difference of any two quantities is equal to the difference of their squares.

Particular theorem, is that which extends only to a particular quantity, as this, in an equalilateral rectilinear triangle, each angle is equal to 60 degrees.

Negative theorem, is that which expresses the impossibility of any assertion, as that the sum of two biquadratic numbers cannot make a square number.

Local theorem, is that which relates to a surface that is either rectilinear, or bounded by the circumference of a circle; as that all the angles in the same segment of a circle are equal.

Solid theorem, is that which considers a space terminated by a solid line; that is, by any of the three cenic sections; as this; that if a right line cuts two asymptotic parabolas, its two parts terminated by them shall be equal.

Reciprocal theorem, is one whose converse is true; as that if a triangle has two sides equal, it has also two angles equal; the converse of which is likewise true, viz., that if the triangle has two angles equal, it has also two sides equal.

THERMOMETER. A glass vessel filled to a certain degree with a liquid, for the purpose of shewing the expansions of that liquid in different temperatures, or for the purpose of shewing the temperature by the corresponding expansion of that liquid, is called a thermometer; i.e., a measure of the temperature.

The fluids most used for thermometers are either mercury or spirit of wine; the latter of which is generally tinged red, by means of cochineal, or Brazil wood, &c. for the pur-
THERMOMETER.

One of rendering it more visible; hence they are denominated the mercurial thermometer, and the spirit thermometer. Other fluids, on account of their clamminess, or of their great irregularity of expansion, are not useful for thermometers.

The most proper and the most useful shape for thermometers, is that of a long tube with a narrow bore, and with a globular cavity at one extremity (see Plate Miscel. fig. 237). The cavity of the bulb C, and part of the tube, as far, for instance, as A, are filled with the fluid; the rest of the tube is either partly, or quite, exhausted of air; and the end B of the tube is hermetically sealed; viz. perfectly closed by melting the extremity of the tube at the flame of a candle or lamp, burned by means of a blowpipe.

When the bulb C is heated, the mercury, or the spirit of wine, is expanded; and not being able to extend itself any other way, all the increment of bulk is manifested in the increase of the diameter of the tube, viz. the whole of the surface A of the fluid will rise considerably into the tube. On the other hand, when the bulb C is cooled, the fluid contracts, and its surface A descends. It is evident, that, certain peribns, the larger is the proportion to the diameter of the cavity of the tube, or the narrower the latter is in proportion to the former, the greater will the motion of the surface A be in the tube. But it must be observed, that when the bulb is very large, the thermometer will not easily arrive at the precise temperature of any place, wherein it may be situated. Some persons, in order to give the bulb a greater surface, and to render it more capable of readily attaining a given temperature, have made it not globular, but cylindrical (which shape was adopted by Fahrenheit), or flat, or bell-like, &c.; but those shapes are improper, because they are liable to be altered by the varying gravity of the atmosphere, consequently those thermometers cannot be accurate.

If a thermometer is heated suddenly, as when the bulb C is immersed in hot water, the surface A of the fluid in it will be seen to descend a little, and instantly after will be seen to rise; the reason of which is, that the heat of the water enlarges the glass first, and is then communicated to the fluid. But, if the contrary, if a bulb of a thermometer is cooled suddenly, the surface A of the fluid will first rise a little, and then will descend; because the cold contracts the glass alone at first, and afterwards contracts the fluid.

Ice is melted by a certain invariable degree of temperature; and water freezes at about the same temperature; therefore, if the bulb C of a mercurial thermometer is placed in melting ice, or in melting snow, and a mark is made on the outside of the tube, even with the surface of the fluid, as at D; that mark is called the freezing-point, though in fact it is the melting-point of ice; the freezing-point of water being not so constant. If the bulb of the thermometer is placed in boiling water, and a mark is made on the glass tube, even with the surface of the fluid within, at E, that mark is called the boiling-point; for in an open vessel, and under the same atmospheric pressure, which is indicated by the barometer, water constantly boils at the same temperature, and an increased fire will force it to evaporate faster, but will not raise its temperature.

Those points being

Fahrenheit's, which is generally used in Great Britain. It is also used throughout this work, unless some other is mentioned. Reaumur's, which is generally used in France, and other parts of the Continent. Celsius's, which has been used in the French elements, under the name of centigrade thermometer.

The Florentine thermometers, which were made and used by the members of the famous academy at Paris, and are some of the first instruments of the sort, were vaguely graduated, some having a great many more degrees than others. But two of their most common graduations seem to be useful, viz. the annuated (or mercurial thermometer, viz. the annual thermometer of the Academy of Sciences, seems to have been graduated already thus,

These are the chief thermometers that have been used in Europe; and the temperatures indicated by the principal of them may be reduced into the corresponding degrees on any of those scales, by means of the following simple theorems; in which R signifies the degrees on the scale of Reamur, F those of Fahrenheit, and S those of the Swedish thermometer.

1. To convert the degrees of Reamur into those of Fahrenheit; $\frac{x}{4} + 32 = F$.

2. To convert the degrees of Fahrenheit into those of Reamur; $(x - 32) \times \frac{5}{9} = R$.

3. To convert the Swedish degrees into those of Fahrenheit; $\frac{5}{9} x + \frac{32}{5} = F$.

4. To convert Fahrenheit's into Swedish; $(x - 32) \times \frac{5}{9} = S$.

5. To convert Swedish degrees into those of Reamur; $\frac{x}{5} + \frac{32}{9} = R$.

6. To convert Reamur's degrees into Swedish; $x \times \frac{4}{5} = S$.

To such readers as are unacquainted with the algebraic expression of arithmetical formule, it will be sufficient to express one or two of these in words, to explain their use: 1. Multiply the degree of Reamur by 9, divide the product by 4, and to the quotient add 32, the sum expresses the degree on the scale of Fahrenheit. 2. From the degree of Fahrenheit subtract 32, multiply the remainder by 4, and divide the product by 9, the quotient is the degree according to the scale of Reamur, &c.

Thermometers have been made of a great variety of shapes and sizes, suitable to the different purposes for which they were intended.

Thermometers for shewing the temperature of the atmosphere, need not have their scales much extended; it is more than sufficient if they go as high as 120°. The lower degrees may be carried down as low as may be necessary for the cold of any particular climate. The mercurial thermometer needs not to be graduated lower than 40° below 0, because at about that degree mercury ceases to be a fluid.
The spirit thermometer may be graduated lower if necessary. We shall therefore mention, that a number which will be noticed hereafter, if a mercurial thermometer and a spirit thermometer are both graduated according to the above-mentioned directions, the two thermometers will not, in their usual indications of the same temperatures, point to the same degrees.

The degrees of thermometers may be delineated on metal, or wood, or paper, or ivory, &c., but such substances should be preferred for the scales of thermometers, as are not apt to be bent or shortened, or otherwise altered by the weather, especially when the instruments are not defended by a glass case, or by a box with a glass face.

The bulb of the thermometer must be clean and colourless; since coloured surfaces are apt to be partially heated by a strong light. The ball of the thermometer ought not to be in contact with the substance of the scale, lest it should be affected by the temperature of that substance.

Thermometers which are to be situated in the open air out of the house, must be at some distance (at least a foot) from the wall, and which shall not possibly be in any way not directly upon them. Fig. 238 represents a thermometer of the most usual shape independent of the case.

For chemical purposes, the bulb and part of the tube of the thermometer, must project some way below the scales, in order that they may be placed in liquids, mixtures, &c.

For other purposes, as for botanical observations, hot-houses, brewing-manufactories, baths, &c., the thermometers must be made longer, or shorter, or narrower, or particular directions must be added to the scales, &c.; but we shall not take any further notice of those fluctuating variations.

It is necessary, however, to describe a sort of thermometers which have been constructed for a particular purpose; namely, for shewing the highest degree of heat or cold, of objects which may be placed in the immediate presence of the observer; as for instance, in the course of the night, or in the hottest part of the day, or even during a whole season.

Thermometers for this purpose have been constructed, peculiarly intended for persons, as by Bernoulli, Kröf, lord Charles Cavendish, &c. but the best of them, which however is not without faults, and of course is in need of improvements, was contrived by Mr. James Siv, and is described in the 72nd vol. of the Philosophical Transactions. Fig. 239 exhibits this instrument, but divested of the scale and frame; ab is a tube of thin glass, about 16 inches long, and \( \frac{7}{8} \) of an inch in diameter; cd is a smaller tube with the inner diameter, about \( \frac{3}{8} \) joined to the larger at the upper end b, and bent down, first on the left side, and then, after descending two inches below ab, upwards again on the right, in the several directions daebg, parallel to, and one inch distant from it. On the end of the same tube at k, the inner diameter is enlarged to half an inch from h to i, which is two inches in length. This glass is filled with highly rectified spirit of wine, to within half an inch of the end ; excepting that of the small tube from d to g, which is filled with mercury. From a view of the instrument in this state, it will readily be conceived, that when the spirit in the large tube, which is the bulb of the thermometer, is expanded by heat, the mercury in the small tube on the left side will be pressed down, and consequently cause that on the right side to rise; on the contrary, when the spirit is condensed by cold, the reverse will happen, the mercury on the left side will rise as that on the right side descends. Further, therefore, which is Fahrenheit's, beginning with 0, at the top of the left side, has the degrees numbered downwards, while that at the right side, beginning with 0 at the bottom, ascends.

The divisions are arranged, by placing this thermometer with a good standard mercurial one in water, gradually heating or cooling, and marking the divisions of the new scale at every 5°. The method of shewing how high a degree of heat or cold is, is, to place the thermometer at the second degree; let it then be in the air, or immersed in a similar substance, and the liquid will always rise or fall, according as the temperature increases or decreases; and therefore it may be depended on, that the scale is correctly adjusted.

The common contrivance for a self-registering thermometer, now sold in most of the London shops, is, one mercurial and the other of alcohol (fig. 243), having their stems horizontal, the former has for its index a small bit of magnetic steel wire, and the latter a minute thermometer, in a tube inserted into small knobs by means of the flame of a candle.

The magnetic bit of wire lies in the vacant space of the mercurial thermometer, and is pushed forward by the mercury whenever the temperature rises, and pushes that fluid against it; but when the temperature falls and the fluid retires, this index is left behind, and consequently shews the maximum. The other index, or bit of glass, lies in the tube of the spirit thermometer immersed in the alcohol; and when the spirit retires by depression of temperature, the index is carried along with it in apparent contact with its interior surface; but on increase of temperature it moves forward and leaves the index, which therefore shews the minimum of temperature since it was set. As these indexes merely lie in the tube, the operation of motion is altogether incon siderable. The fluid is brought to the mercury by applying a magnet on the outside of the tube, and the other is duly placed at the end of the column of alcohol by inclining the whole instrument.

The operation of this instrument has been thus explained: When the surface of the column of spirit is viewed by a magnet, it is seen to have the form of a concave hemisphere, which shews that the liquid is attracted by the glass. The glass in that place is consequently attracted in the opposite direction, by a force equal to that which is employed in maintaining that concave figure; and if it was at liberty to move, it would be drawn back till the flat surface was restored. Let a small stick or piece of glass be to lose within the tube and to protrude into the vacant space beyond the surface of the alcohol. The fluid will be attracted also by the glass, and form a concave between its surface and the bore of the tube. But the small interior piece, being quite at liberty to move, will be drawn towards the spirit so long as the attractive force possesses any activity; that is, so long as any additional fluid hangs round the glass, or, in other words, until the end of the stick of glass is even with the surface. Whence it is seen that the small piece of glass will be resisted, in any action that may tend to protrude it beyond the surface of the fluid; and if this resistance is greater than the force required to slide it along in the tube (as in fact it is), the piece must be slide along as the alcohol contracts; so as always to keep the piece within the tube, this fact is accordingly observed to take place.

It might at first sight be imagined that equal increments of heat would cause fluids to expand equally; viz. that if the heat is increased gradually by one degree, two degrees, &c., the fluid that heated fluid thus heated would expand its bulk by a certain quantity, then by twice that quantity, three times that quantity, and so on. But this is not the case, and every fluid seems to follow a particular law of expansion.
Mercury seems to expand more equally than any other fluid. Yet its increments of bulk are not quite proportional to the increments of heat, with other fluids the irregularity of expansion is very considerable.

One cubic inch of mercury, or one measure whatever of it, at 32° of temperature, when heated to the temperature of boiling water, viz. at 212°, will be found increased in bulk by the quantity 0.01386. This fluid metal boils and becomes a vapour at 600° of Fahrenheit's thermometer, and it becomes a solid at 40°; viz. 72° below melting ice. Below that point, viz. —40°, it contracts irregularly.

Spirit of wine boils at about 180° and the promise probably never freezes. When brassy, or a mixture of water and spirit, freezes, it is the water that is solid, but the spirit will be found collected together in one or more bubbles, in some part of the ice.

From all that has been said with respect to the expansion of fluids, it appears that, on account of the variability of the rate of expansion, mercury and spirit of wine are the only two fluids which can be used for thermometers; observing that some compensation must be made by the spirit thermometer, in order to make it correspond with the scale of the mercurial thermometer. But the mercurial thermometer cannot indicate a temperature higher than 600°. Hence various ingenious inventors have endeavored to devise instruments capable of indicating the higher degrees of heat, which would be of great use in philosophy, chemistry, and various arts; but the only useful contrivance that has been made is that of the late Mr. Wedgewood. This ingenious gentleman applied to the measuring of high degrees of heat, a singular property of argilaceous bodies, a property which obtains more or less in all such kind of them, as far as an argilaceous substance, when exposed to fire, is diminished in bulk by it, or does the bulk increase again after cooling; and this diminution of bulk is proportional to the degree of heat to which the substance has been exposed.

This property may seem to be a deviation from the general rule, viz. that heat expands all sorts of bodies; but it is to be observed that any heat enables them to contract their dimensions; but in this case it must be considered that the clay pieces contract and remain contracted, because some substance, viz. water and an aeiform fluid, is separated from them by the action of the fire.

Mr. Wedgewood's thermometer, or apparatus for measuring the high degrees of heat, consists of small pieces of clay of a determined length, which are to be placed in the furnace. Each of these pieces, after they have been exposed to the fire, Fig. 241 represents the gauge, which is either of brass or of porcelain. Fig. 242 represents a section of the same; and the letters refer to the like parts in both figures. EFGH is a smooth flat plate; AC, BD, are two rulers of equal pieces, a quarter of an inch thick, and fixed fast upon the plate, so as to form a converging canal ABCD, whose width at CD is three-fourths of the width at AB. The whole length of the canal from AB to CD, is divided into 240 equal parts, and the divisions are numbered from the wider end. The liquid to be expanded as to its exact degree, is put into the canal, and is afterwards diminished in bulk by the action of fire (as the thermometrical pieces which will be described in the next paragraph), it may then be passed further in the canal, and more so according as the diminution is greater.

The thermometrical pieces are small cylinders of clay, a little flattened on one side. They are nearly as much in diameter as they are in length. When one of these pieces is to be used, it is proper to measure it first by placing it in the gauge at AB; for sometimes the pieces are a few degrees larger or smaller than the distance AB, which excess or defect being ascertained, must afterwards be allowed for. P represents one of these pieces set in the gauge for measurement.

The piece is then placed in the furnace, or between the ends of Fahrenheit's thermometer, at the end of the operation, or at any period, and, when grown cold, is measured by sliding it as far as it will go, into the canal of the gauge, the number of divisions against the scale of the gauge will shew the contracted dimensions of the piece, and of course the degree of heat to which it has been exposed.

It will be found that these pieces will go very little beyond 0 in the canal, if they have been exposed to a low degree of heat; or go to 27 or 28, if they have been exposed to the heat in which copper melts; to about 90° if exposed to the welding-heat of iron; or about 160° if exposed to the greatest heat that can be produced with charred pine or a well constructed air-furnace, &c.

The same thermometrical piece which has been used before, may be used again for higher degrees of heat, but not for lower degrees.

It is now necessary to shew the correspondence between the scale of this, and the scale of Fahrenheit's mercurial thermometer.

As the mercurial thermometer cannot show a temperature higher than 600°, and Wedgewood's thermometer cannot shew a temperature lower than 60°, it shows degrees between these limits, but it is necessary to shew the intermediate degrees, and which might reach some degrees below 600°, and some degrees above the temperature of a red heat. Mr. Wedgewood chose a piece of silver, the expansion of which measured in a gauge made for the purpose, similar to the gauge figured 241, might indicate the degrees of temperature between the two thermometers; with this instrument he first found the correspondence between the scale of Fahrenheit's and the last-mentioned gauge, by placing them alternately in water of the temperature of 50°, and in boiling water. Then he found the correspondence between the degrees of the gauge of the silver piece, and that of the earthen thermometrical pieces, by placing them both at the same time in different and higher degrees of heat; lastly, by computation from those results, he determined the correspondence between the degrees of Fahrenheit's scale and those of his own thermometrical gauge.

It was found that one degree of Wedgewood's thermometer is equal to 150° of Fahrenheit's; and that the 0 of Wedgewood's coincides with the 177.5° of Fahrenheit's; from which a comparison of the two thermometers may be made, or rather of the imaginary extensions of their two scales; for, in fact, Fahrenheit's thermometer cannot show a figure higher than 320°, and Wedgewood's cannot show a figure below 50°; so that it may be observed that the degrees of Wedgewood's scale are supposed to show equal increments of heat, whereas in truth we do not know whether the clay thermometrical pieces contract in proportion to the increments of heat; which shows that, though this is the best known thermometer for measuring the higher degrees of heat, yet an improvement of the same, or some other manageable and more accurate contrivance, is highly desirable.

Upon the whole it appears, that the spirit thermometer enables us to measure the degrees of heat as low as has ever been experienced, either naturally, or by artificial cooling; that the mercurial thermometer enables us to measure from a red heat up to the farthest extent of that scale, viz. to its 240th degree, which is reckoned as equivalent to 327°27' of Fahrenheit's scale.

THESIUM, Base flueinum, a genus of plants of the class pistacia, and order nooxynagia. The calyx is monophyllous, with the stamens inserted in the axil of each leaf, and one seed, which is inferior. There are nineteen species; one of which is a British plant, the linophyllum or bastard-tobacco. It has a foliaceous panicule with linear leaves, and flows in June and July.

TILLAPI, Bastard-cress, or Mithridate mustard, a genus of plants of the class tetradyum, and order silicoua; and in the natural system ranging under the 39th order, silicoua. The pod is enamour, obcordate, and polyspermous; the valves are boat-shaped, and marginated and carinate. There are 14 species; of which six only are natives of Britain. 1. The arvense, treacle-mustard, or pennycress, which is a weed, like garlic, and has a white flower. 2. The hirtum, or perennial mithridate mustard. 3. The campstire, or mithridate mustard. 4. The montanum, or mountain mithridate mustard. 5. The perennis, or treacle-mustard. 6. The burras pastoris, or shepherd's purse. The seeds of some of these species have an acrid biting taste, approaching to that of the common mustard; with which they agree nearly in their pharmacutic properties.

THIRD, in music, an interval so called because it contains three diatonic sounds. The Greeks not admitting the third as a consonance, it obtained no general name amongst them; but took that of the lesser or greater interval from which it was formed.

There are four species of thirds; two consonant, and two dissonant. The consonants are: first, the major third, called by the ancient dition, composed of two tones; secondly, the minor third, called hemitonic, consisting of a tone and a half. The dissonant thirds are, first, the diminished third, composed of two major semitones; secondly, the superius third, composed of two tones and a half. This last interval, not having place in the same mode, or key, is never used either in harmony, or in melody. The Italians sometimes introduce the
diminished third in airs, but it is never used in harmony.

The dominant thirds are the spirit of harmony, particularly the major third, which is sonorous and brilliant; the minor third is more tender, and even pathetic; a difference of character from which skilful composers derive some of the best and most poignant effects.

The old French theorists had almost as severe laws respecting the thirds as we now observe in regard to fiftis and eightis. It was the best forbidden to have two in immediate succession, even of different kinds, particularly in the same direction.

THIRTEENTH, in music, an interval forming the octave of the sixth, or the sixth of the octave. It contains twelve diatomic degrees, i.e. thirteen sounds.

THOA, a genus of the monocotyledon poyantria class and order of plants. There is no calyx or corolla; the male stamens are numerous; two; seed three or four-cleft; seed is grown in a brittle shell, covered with a bristly nect. There is one species.

THORACIC, a term applied to an order of fishes in the Linncean system; the character of this order of fishes is, that they have but two lateral fins placed directly under the thorax. Of this order there are 21 genera, viz. the

THORACIC DUCT. See ANATOMY.

THORAX. See ANATOMY.

The theory of insects is the back part of the breast. See ENTOMOLOGY.

THORNBACK. See RAI.

THOINUING, a genus of plants of the class diandria, and order monogynia. The corolla is quadrilateral, the calyx quadri- partite, and the anther sessile. There is only one species, a tree of Madagascar.

THRESHING, or Threshing, in agriculture, the art of beating the corn out of the ear.

THRESHING-MACHINES. The threshing of corn by means of machinery, has been long in use in the northern districts of the kingdom, and mills of this sort are now becoming general in most parts of the country; and upon arable farms of considerable extent, they cannot but be highly advantageous, as they save much labour and expense. In the making of those machines, attention should always be had to the size of the farms, or rather the quantity of grain that may be grown on them, and the mill proportioned accordingly. They are mostly constructed on the principles of the flax-mill, and are moved either by water or horses, the first by far the best method where it can be had; the grain by these machines being, in a manner, swung out of the ears by means of beaters which are attached to a cylinder that moves with very great velocity. Since the introduction of these machines, many improvements have been made on them; a screen has been added for the grain to pass through into a winnowing-machine, and a circular rake to remove the straw from it; as

before this addition the straw was forced out from the beater upon the upper barn-floor, and raised and laboriously and putting into order, which by this contrivance is saved. In working these mills, four persons are commonly necessary; one takes the sheaf from the stack, another places it ready for the third who is to feed the mill, and the fourth removes the straw to prevent its collecting in too large a quantity. It has been objected to these machines, that they do not thrash some sorts of grain clean; this has been particularly the case with barley. It is, however, observed by an intelligent writer, that the circumstance on which the good threshing of this kind of grain depends, is the iron covering under which the beating-wheel, having six beaters, moves; in some machines this is fixed, while the beating-wheel is capable of being raised or depressed at pleasure; but a recent improvement is, to render the iron roof movable, and the wheel fixed; and the iron is placed so near to the beaters that the grain is rubbed, as well as stricken out of the ear. In some machines of this sort, the beaters are a little rounded; but it is probably a better practice to have them of a rectangular form.

In some large mills of this kind the rollers take in about three hundred inches of grain in a minute. The medium length of the straw being estimated at about thirty inches, and supposed there would be ten feet deep to引进 the machine at a time, the whole sheaf will be equal to sixty inches, and the machine, when supplied with a middling quantity of water, will thrash five sheaves in a minute. But in respect to the performance of these mills much must depend on the attention with which they are fed, as a small neglect in this point will make a very considerable difference in the quantity of work done.

An excellent description of a mill of this nature is given in a late publication, in which it is remarked, that in such mills five people are commonly necessary to keep the work going on without interruption; yet this depends greatly on the construction of the machines, some of them being so contrived, that the work can be performed with much fewer hands. The manner in which one person operates is this: One person is employed in the constant work in carrying the sheaves to the man who feeds or puts the unthreshed corn into the machine, and in loosing the bands; another is required to feed the machine; a third to carry off the straw; the fourth to attend the samers, and lay aside the cleaned grain; and a fifth, where horses are made use of, to take care that they go regularly; and thus by means of five men and four horses they will through at the rate of five quarters in the hour on a medium, and when the crop is rich, and easily threshed, considerably more: consequently if a threshing-mill was to be employed for a whole day, or nine hours, it would thresh forty-five quarters; but in that case it would be necessary to employ two sets of horses. The expense is calculated in this manner:

Hire of eight horses, at 22. 6d. each per day. 1 0 0
Five men's wages, at 1s. 6d. each, 0 7 6
Total. 1 7 6

In this account the hire of the men and horses is, it is conceived, charged at the lowest rate, and that the expense of thrashing one quarter would cost about 1l. 7s. 6d. or about 7d. each quarter. But that taking the average expense of thrashing forty-five quarters of grain with horses, throughout the whole kingdom, including an equal proportion of all kinds, it cannot be, it is supposed, estimated at less than 3l. 7s. 6d. or 1s. 6d. each quarter, which makes a difference of about 1s. 6d. each. It must be observed, that since the introduction of these mills, the grain is thrashed by the ordinary servants on the farm, and without in any material degree obstructing the operations in the field; farmers are in general employing their men and horses in this business in bad weather, where other operations cannot be carried on.

The whole expense of constructing a threshing-mill, including the building of the shed for covering the great wheel, does not, in almost any case, exceed 100l. The annual repayment of the money, on another, amount to 5l., which added to the interest of the prime cost, makes the yearly expense 10l. 5s.; a sum for which any quantity of grain, however great, that may be supposed to be saved on the threshing-mill, and that to in a manner so much superior to what can be done by manual labour. The expense either of erecting these machines, or of keeping them afterwards in repair, must be considered by every intelligent occupier of a corn farm as a secondary object, when compared with the advantages that are derived from them; such as the performing of the operation at less than half the ordinary price, and affording the farmer the means of securing his grain from being embezzeled; besides, the saving, in regard to superior clean threshing, as has been now well ascertained, is not only more than the annual expense of repairs, but so great as, on a farm of considerable extent, to reimburse the farmer for the whole of his expenditure in the course of a few years. Considering, therefore the increasing scarcity of labourers, and the recent increase in the price of the better cultivated parts of the kingdom, the introduction of threshing-mills into common use cannot but be highly beneficial.

There is, however, one difficulty in the introduction of threshing-mills into the southern parts of the kingdom, which arises from the manner of harvesting all kinds of grain, except wheat, which cannot probably be easily removed; as the corn, in order to be clean threshed, should be put into the machine as straight and regular as possible. For while the sheaves, after being loosened and spread on the board, so as to be easily taken in by the feeding rollers, are passing between them, they keep the straw steadily, by which means the strokes of the beaters or scutters operate with more force and effect in separating the grain from the ears; whereas, if the unthreshed corn goes in sideways or irregularly, the threshers can have but little power upon it. This would no doubt frequently happen, threshing corn which has been mown with the scythe, and which is harvested in every respect like hay; so that unless the unthreshed grain is put into the mill in small quantities, it is almost impossible.
that it can be completely separated from the straw.

But though, when the size of the machine is considered, the expense of erecting it may be from sixty to one hundred pounds, according to situation and materials, smaller ones may be erected at much less, as from thirty to fifty pounds.

Some of the early mills have rollers or small mill-stones added to them, for the purpose of crushing and grinding grain for horses, swine, and other animals; and also instruments for cutting straw into chaff.

On the whole, this line of employing machines of this kind, it is remarked by an able writer, that it is the only method left for having the corn cleanly and properly threshed. They are so quick in the work, that the whole may be done under the eye of the master, and the corn secured in the granary without the least pilfering. The saving, by this means of threshing, in the extra quantity of corn procured, and the security against having the corn stolen, or injured in any way, especially in wet seasons, and with smutty wheat, which is threshed by it without any mischief being done to the sound grain, the smut not being crushed comes out whole, and is blown away with the chaff.

The principal objections that have been made to these machines, are the great expense of erecting and using them, their tendency to diminish the labour of the poor, and their allowing too great a supply of straw at a time. These objections are, however, of little consequence, when the general utility and advantages of such machines are considered; besides the latter are either such as have natural and deep root from them, or as may be readily obviated. The difficulty in regard to the straw may be easily removed, by having it properly stacked up or cut into chaff.

THRAVE, or THREAVE of corn, twenty-four sheaves, or four shocks of six sheaves to the shock, though, in some counties, they only reckon twelve shocks to the thrave.

THREAD, a small line made up of a number of fine fibres of any vegetable or animal substance, such as flax, cotton, or silk; from which it takes its name of linen, cotton, or silk thread.

Linen and cotton thread may be dyed of a durable and deep black by a solution of iron in sour beer, in which the linen is to be steeped for some time, and afterwards boiled in madder. See the article DYEING. Thread may be easily bleached by the oxymuriatic acid discovered by Mr. Scheele. This acid whitens cloth remarkably well, but it is still more advantageous for bleaching thread.

THREATENING LETTER. If any person shall send any letter threatening to accuse, defame, or threaten, punishable with death, transportation, pillory, or other infamous punishment, with a view to extort money from him, he shall be punished at the discretion of the court, with fine, imprisonment, pillory, whipping, or transportation. 80 C. 11. c. 24. But if the writer of a threatening letter delivers it himself, and does not send it to any other person under this act, Lösch's Corl. Law, 351.

THRINAX, small Jamaica junc-palm; a genus of plants of the natural class of palm and order of flaccid-sedges. The calyx is sepalate, there is no corolla; there are six stamens; the stigma is emarginate, and the berry monosperous. This plant was brought from Jamaica to Kew gardens by Dr. Threlfall.

THRIPS, a genus of the order hirudiptera; the generic character is, many insecutores; antennae the length of thorax; body linear, abdomen reflexed upwards; wings four, straight, long, narrow, incumbent on the back in length. The larva is a great consisting of very small insects, which are principally found on flowers. The antennae are submoniform, and of the length of the thorax; the wing is secure or incomparable, long and parallel between the neck or head; the body of a lengthened or sublinear shape, and the abdomen is at pleasure bent upwards or backwards; the wings are four in number, narrow, long, incumbent, and very slightly, or scarcely, crenulate.

The most familiar example of the genus is the thrips physapus of Linnaeus, which is a very small slender insect, of a black colour, very frequently seen during the spring and summer on various flowers. It consists especially on what are termed the compound flowers, as dandelion, &c. It wanders about the petals of the flower, descending to the bottom of the flowers, occassionally creeping at intervals, and often slipping from place to place, in performing which action it is observed suddenly to turn back its abdomen, so as nearly to touch the thorax with its tip. The wings are of a transparent quality, white, very narrow, and when properly magnified, are observed to be edged and tipped with hairs growing gradually longer as they approach the tips, where they are of considerable length. They are much shorter than the upper, beneath which they are, in general, almost concealed; the antennae consist of six joints, and the feet are tipped with an expanse and apparently vascular process, enabling the little animal to adhere at pleasure with the greater security to any particular substance. All these particulars require a microscope for their investigation, the whole insect not exceeding the tenth of an inch in length. This small species resembles the complete insect, but is destitute of wings; when very young it is white, and afterwards of a yellowish or reddish colour, and like the complete insect, is seen wandering about the petals of flowers.

The thrips physapus has been supposed to do much injury to wheat, rye, &c. by causing the young flowers to decay, thus preventing the growth of the embryo grain. This opinion, however, has been somewhat corrected by erroneous; who have contended that the thrips does not attach itself to such of the cereals as are in a perfect healthy state, but rather to such as are diseased by having the embryo grain covered with the growth of a very minute fungus, often growing on wheat; &c. and belonging to the genus acidioma or lyco-

THRU, the eoror viza, a genus of plants of the class monoclad, and order monoclad; and in the natural system ranging under the 35th order, conifera. There are four species of this genus, which are mostly known, the brahimiens, a shrub of Brazil.

THUYA, the orbor viza, a genus of plants of the class monadacl, and order monadacl; and in the natural system ranging under the 35th order, conifera. There are four species of this genus, which are mostly known, the brahimiens, a shrub of Brazil.

THYME, or Thymus vulgaris; a genus of the plant kingdom, and order monadacl; and in the natural system ranging under the 35th order, conifera. There are four species of this genus, which are mostly known, the brahimiens, a shrub of Brazil.
into a hard black enamel. With borax it exhibits the same phenomena, or even when the stone is simply heated at the end of a fire.

A specimen of thummerstone, analysed by Klaproth, contained

52.7 silica
23.6 alumina
9.4 lime
9.6 oxides of iron, with a trace
of manganese.

97.3

A specimen, analysed by Vauquelin, contained

44 silica
14 lime
10 oxide of iron
4 oxide of manganese

99.

THUNDER. See Electricity.

THUNBERGIA, a genus of plants belonging to the class dicotyledon angiosperma. The calyx is double; the corolla bell-shaped; capsules beaked. There are 5 species.

TIJUS. See RESTIES.

TIYMBRA, a genus of the class dicotyledon angiosperma. The calyx is two-lipped; seeds semiblind. There are 3 species.

TIYMYUS, THYME, a genus of plants of the class dicotyledon, and order gynnopteridae; and in the natural system ranging under the 42d order, verticillata. The calyx is bilabiata, and its throat closed with soft hairs. There are 22 species; of which only two are natives of Britain, the serpyllum and acinos.

1. The serpyllum, or mother of thyme, has pale red flowers growing on round heads, terminal; the stalks are procumbent, and the leaves plane, obtuse, and dilated at the base.

2. The acinos, or wild basil, has flowers growing in whorls on single footstalks; the stalks are erect and branched; the leaves acute and serrated. The thymus vulgarus, or garden thyme, is a native of France, Spain, and Italy. The attachment of birds to this and other aromatic plants is well known. In the experiments made at Upsal, sheep and goats were observed to eat it, and swine to refuse it.

Thymus, in anatomy, a gland, which in infants is very remarkable; it is situated in the upper part of the thorax, immediately under the sternum, and lies upon the pericardium, and on the trunk of the aorta and of the vena cava. See ANATOMY.

TIYNNUS, a genus of the hymenoptera order of insects. The generic character is, mouth hairy, with an incised mandible; the jaw short and straight; lip longer than the jaw, membraneous at the tip, and trifid, the middle division emarginate; tongue very short, involute; feelers four, equal, filiform; antennae cylindrical, the first joint thicker.

There are four species, three inhabiting New Holland, and the fourth is found in Africa.

THYROID GLAND. See ANATOMY.

THYRUS, in botany, a mode of flowering resembling the cone of a pine.

TIARELLA, a genus of plants of the class dicotyledon, and order gynnopteridae, and in the natural system ranging under the 13th order, sylvestrense. The calyx is quinquepartite; the corolla pentapetalous, and inserted into the calyx; the petals are entire; the capsule is unilocular and bivalve, one valve being less than the other. There are two species, the cordifolia and trifoliata, natives of North America.

TIBIA. See ANATOMY.

TIDALIS, or THIBRUS. See ANATOMY.

TIDES. See Astronomy.

Tide-waiters, or tide-men, are inferior officers belonging to the custom-house, whose employment it is to watch or attend upon ships, until the customs are paid; they get this name from going on board ships on their arrival in the mouth of the Thames or other part, and in the tide of the holders, or those of the measure, or those of the tide; a measure of liquid things, as wine, oil, &c., containing the third part of a pipe, or forty-two gallons. See MEASUREMENT.

TIGER. See FELIS.

Tiger-shell, a beautiful species of webula, of a dusky-red colour, spotted all over with large irregular blotches of white: it is brought from the East Indies, and is about two inches in length, and about an inch in diameter.

TILE, in building, a sort of thin brick, used on the roofs of houses; or more properly a kind of clayey earth, kneaded and mixed with water, dried and salted, and then allowing it to stay in the air a kiln, like a brick, and used in the covering and paving of different kinds of military and other buildings. The best brick-earth only should be made into tiles.

The thinness for all sorts of uses may now be comprised under seven heads, viz. 1. The plain tile for covering of houses, which is flat and thin. 2. The plain tile for paving, which is also flat, but thicker, and which is 9, 10, or 12 inches. 3. The pantile, which is also used for covering of buildings, and is hollow, and crooked, or bent, somewhat in the manner of an S. 4. The Dutch glazed pantile. 5. The English glazed pantile. 6. The gutter-tile, which is made with a kind of wings. And 7. The hip or corner-tile.

Tiles, plain, are best when they are firmest, soundest, and strongest. Some are dusky-coloured, and others rich in colour. The dusky-coloured are generally the strongest. These tiles are not laid in mortar, but pointed only in the inside.

Tiles, paving, are made of a more sandy earth than ordinary or common, or plant tiles for covering large spaces; the materials for these last must be absolute clay, but for the others a kind of loam is used. These are made thicker and larger than the common roof-tiles; and when care has been taken in the choice of the earth, and the management of the fire, they are very regular and beautiful.

Tiles, pan, when of the best kind, are made of an earth not much unlike that of the paving-tiles, and clay of the same; but the best sort of all is a pale-coloured loam that is less sandy; they have about the same degree of fire given them in the baking, and they come out nearly of the same colour. These tiles are laid in mortar, because the roof being very flat, and many of them warped in the baking, they will not cover the building so well that no water can pass between them.

Tiles, pan, Dutch glazed, get the addition of glazing in the fire. Many kinds of earthy matter running into a glassy substance in great heat, is a great advantage to them; preserving them much longer than the common pan-tiles, so that they are very well worth the additional charge that attends the using them.

Tiles, pan, English glazed, are in general not so good as the Dutch ones under that denomination, but the process is nearly the same.

Tiles, Dutch, for chimneys, are of a kind very different from all the rest. They are made of a whitish earth, glazed and painted with various figures, such as birds, flowers, or landscapes, in blue or purple colour, and sometimes quite white; they are about 0.5 inches thick, and which are made by the Dutch in each way, and three quarters of an inch thick. They are seldom used at present.

Tiles, gutter, are made of the same earth as the common pan-tiles, and only differ from them in shape; but it is advisable that particular care be taken in tempering and working the earth for these, for none are more liable to accidents. The edges of these tiles are turned up at the larger ends for covering the tiles; they are seldom used where lead is to be had.

Tiles, hip or corner, are at first made flat, like pan-tiles of a quadrangular figure, whose two sides are right lines, and the ends arches of circles; the upper end concave, and the lower convex the latter being about seven times as broad as the other; they are about 10.5 inches long; but before they are burnt, are bent upon a mould in the form of a ridge tile, having a hole at the narrow end, to nail them on the hip-corner for covering the roof.

Tiles, ridge, are made to cover the ridges of houses, and are made in the form of a semi-cylindrical surface, about 13 inches in length, and of the same thickness as plain tiles; their breadth at the outside measures about sixteen inches.

TILLA, lime, or Linden-tree, a genus of plants of the class polyantha, and order morgynia, and in the natural system ranging under the columnae. The calyx is quinquepartite; the corolla pentapetalous; the capsule semibifid; the juice crimson, quinquvalve, and opening at the base. There are four species; the europaea, americana, pubescens, and alba. The europaea, or common lime-tree, is generally supposed to be a native of Britain; but we are informed by Mr. Coxe, that Mr. Pennant told him (on what authority is not mentioned) that it was imported into England before the year 1652.

The wood is light, smooth, and of a spongy texture, used for making laths and tables for shoemakers, &c. Ropes and bandages are made of the bark, and mats and rustic garnments of the inner rind, in Carniola and some other countries. The lime-tree contains a gummy juice, which being repeatedly boiled and clarified, produces a substance like sugar.

TILLANDSIA, a genus of the hemiphylia monogynia class of plants, with a tubulated monopetalous flower, trifol at the limb; the fruit is a long, oblong, acuminate capsule, formed of three valves, and containing only one cell, with numerous seeds affixed to a long capillary plume. There are 16 species.

TILLER of a ship, a strong piece of wood fastened in the head of the rudder, and in small ships and boats called the helm.

In ships of war, and other large vessels,
the timber is to be felled, the statute requires it to be done then, for the advantage of tanning.

After timber has been felled and secured, it is hauled by hand; for which purpose some of the men advise it to be laid up in a very dry airy place, yet out of the wind and sun, or at least free from the extremities of either; and that it may not decay, but dry evenly, they recommend it to be laid up with wings, and covered with carting. It must not stand upright, but lie all along, one piece over another, only kept apart by short blocks interposed, to prevent a certain mouldiness which they otherwise apt to contract in sweeping one another; from which arises frequently a kind of fungus, especially if there are any sappy parts remaining. Others advise the planks of timber to be laid for a few days in some cool or dark place, to work off the sap, and extract the sap, and afterwards dry them in the sun or air. By this means, it is said, they will be prevented from either chopping, casting, or cleaving, but against shrinking there is no remedy. Some argue that placing them in the earth, others in a hot; and some for scourching and seasoning them in fire, especially piles, posts, &c., which are to stand in water or earth. The Venetians have not found the method of preserving wood, which is done after this manner: they put the piece to be seasoned into a strong and violet flame, in which they continually turn it round by means of an engine, and take it out when it is every way covered with a black coaly crust; when the internal part of the wood is so hardened, that neither earth nor water can damage it for a long time afterwards.

After timber has been well seasoned and fixed in their places, care is to be taken to defend or preserve them; to which the smearing with lime-wood oil, tar, or other oleaginous matter, contributes much. (being the principal danger which they are exposed to is shrinking.) The mean circumference be found in feet and decimals of a foot; square it, multiply this square by the decimal 0.77577, and the product by the length. Ex. Let the mean circumference of a circle be 24 feet. Then $0.77577 \times 24 = 202.615$, the number of cubical feet in the tree. The foundation of this rule is, that when the circumference of a circle is 1, the area is $0.775774715$, and that when the mean circumference be found in feet and decimals of a foot; square it, multiply this square by the decimal 0.77577, and the product by the length. According to the planck's method, the tree of the last example would be computed at 159.13 cubic feet only.

But the common way used by artificers for measuring round timber, differs much from this rule. They call one-fourth part of the circumference the girth, which is by them reckoned the side of a square whose area is equal to the area of the section of the tree; therefore square the girth, and then multiply by the length of the tree. According to the planck's method, the tree of the last example would be computed at 159.13 cubic feet only.

For measuring hewn or square timber, the custom is to find the middle of the length of the tree, and there to measure its breadth, by clapping two rules to the sides of the tree, and measuring the distance betwixt them; in like manner they measure the breadth the other way. If the two are found unequal, they are added together, and half their sum is taken for the true side of the square.

Timber, strength of. "After spending much time," says Mr. Smart, "in making various experiments, and comparing the results with those of Buffon, Belidor, &c., the differences were so great, that it would be wasting time to enumerate them; I shall therefore only mention the means of observations necessary to be known by all those mechanics who use timber; and point out some evident errors in a table of Belidor's, supposed to be the result of the best set of experiments ever produced in transverse strain.

He tells us, that a bar of wood, thirty-six inches long, and one inch square, supported at the ends by two props, will break with a weight of 187 pounds, and that the stress of the load is loose at the ends; but if the ends are firmly fixed, it will require 283 pounds to break it.

"This appeared to me so great an error, that I was induced to put little or no confidence in many of his experiments; and, in consequence, I made two fathoms of fir, of the same dimensions, one with a strong shoulder at each end, to prevent its bending, which having firmly fixed in a frame, I carried a weight more than ten times greater than that which was loose."

The fibres of timber requiring so great a force to tear them asunder in a vertical direction, and being easily broken by a transverse strain, which cannot be resisted by the parts lying nearly an equal weight in all directions, opens a wide field for useful experiments.

All timber-trees have their annual circles, or growths, which vary greatly according to the soil and exposure of the sun. The northeast side of the trees (being much smaller in the grain than the other parts, which are more exposed to the sun) is strongest for any column that has a weight to support in a vertical direction; because those circles, being nearer each other, and the area contains a greater quantity of them; nor are they so liable to be compressed by the weight, or to slide past each other, as when they are at a greater distance. On the other hand, this part of the tree is not fit for a transverse strain; because the nearer the hard circles are to each other, the easier the beam will break, there being so little space between them, and the hard circle forms a thin, smooth wire, which cannot slide past the other upon: but that part of a tree, the tubes of which are of a greater distance, or of larger grain, is more elastic, and requires a greater force to break it; because the outside fibre on the convex side; cannot slide past the next, nor is the one pressed upon it, which forms the full-crum to break it on. It is generally observed in large timbers, such as masts, that the fracture is seldom on the convex, but usually on the concave side; which is owing to the fibres on the concave side being more readily forced past each other, and those on the convex being so difficult to be torn asunder, that they cannot snap, in consequence of the largeness of the segment of the circles, they describe when on the strain. The curve described by the inner layers of the wood being so large, and indeed little less than a straight line, cannot form a fulcrum to break the outer ones upon; and as the convex side, or that on which the fibres are extended, ought to be always free from any mortise or incision on the outside, the strength decreases as it approaches the centre.

Fig. 7, 8, 9, and 10, Plate Ship-build, describe the simple method invented by Mr. George Smart, of converting all timber that is straight, and intended for square beams, to great advantage in general.
is generally called the major time, and that of the reversed \( \gamma \) the minor time.

The moderns have added to the old music a combination of times; but still we may say that we have now no more than two times common and triple: since the time of nine crotches, or nine quavers in a bar, is but a species of triple time; and that of six crotchets, or six quavers in a bar, though called a compound time, is only measured by two beats, one down and one up, as absolutely common time as that of four crotchets in a bar.

With respect to the velocities of the different species of time, they are as various as the measures and modifications of music, and are generally expressed by some Italian word or phrase at the beginning of each movement, as largo (rather slow), presto (quick), &c. But when once the time of the improvements has been once, it cannot be perfectly equal, that is, every bar is to take up the same quantity of time, and the corresponding divisions of the bars are to be perfectly symmetrical with respect to each other.

**TIMEKEEPERS, in a general sense, denote instruments adapted for measuring time. See CHRONOMETER.**

In a more peculiar and definite sense, time-keeper is a term first applied by Mr. John Harrison to his watches constructed for determining the longitude at sea, and for which he received, at different times, the parliamentary reward of twenty thousand pounds. Several other artists have since received also considerable sums for their improvements of time-keepers, as Arnold, Mudge, &c. See LONGITUDE.

This appellation is now become common among artists, to distinguish such watches as are made with extraordinary care and accuracy for nautical or astronomical observations.

The principles of Mr. Harrison's time-keeper, as they were communicated by himself to the commissioners appointed to receive and publish the same in the year 1765, and after, are as follows:

In this time-keeper there is the greatest care taken to avoid friction, as much as can be, by the wheels moving on small pivots, and in roller-holes, and high numbers in the wheels and pinions.

The part which measures time goes but the eighth part of a minute without winding up; so that part is very simple, as this winding-up is performed at the wheel next to the balance-wheel, by which means there is always an equal force acting at that wheel, and all the rest of the work has no more to do in the measuring of time than the person that winds it once a day.

There is a spring in the inside of the fusee, which I will call a secondary main spring. This spring is always kept stretched to a certain tension by the main spring; and during the time of winding up the time-keeper, at which time the main spring is not subjected to act, this secondary spring supplies its place.

In common watches in general, the wheels have about one-third the dominion over the balance, but in this balance-spring bar that is, if the power which the balance-spring has over the balance is called three, that from
...and that the balance, when at rest, the force of the error, acting on the pendulum, balances the spring, and makes the balance, when at rest, to a greater degree in proportion to the vibration that is a) pitch, than the force of the weight of the pendulum a b) common spring can move the pendulum on the perpendicular, when it is at rest.

"My timekeeper's balance is more than three times the weight of a large-sized common watch balance, and three times its diameter, and a common balance goes through about six inches of space in a second, but mine goes through about twenty-four inches in that time; so that my timekeeper only these advantages over a common spring; it is a good example of the advantage of an exceedingly strong spring, and at the same time, I may be allowed to say, an artificial cycloid, which acts at the spring; so that if these contrivances, let the balance vibrate more or less, all its vibrations are performed in the same time, and therefore if it goes at all, it must go true. So that it is plain from this, that such a timekeeper goes entirely from principle, and not on chance.

We must refer those who may desire to see a minute account of the construction of Mr. Harrison's timekeeper, to the publication of the Commissioners of longitude.

We shall here subjoin a short view of the improvements in the Harrison's watch, which will be presented to the Board of longitude by Mr. Ludlam, one of the gentlemen by whom, by order of the Commissioners, Mr. Harrison discovered and explained the principle upon which his timekeeper is constructed. The defects in common watches which Mr. Harrison proposes to remedy, are these: 1. That the main spring acts constantly with the same force upon the wheels, and through them upon the balance. 2. That the balance, together with an equal force, or meeting with a different distance from the air, or the oil, or the friction, vibrates through a greater or less arch. 3. That these unequal vibrations are not performed in equal times. And, 4. That the balance-spring is altered by a change of heat.

To remedy the first defect, Mr. Harrison has contrived that his watch shall be moved by a very tender spring, which never unrolls itself more than one-eighth part of a turn, and acts upon the balance through one wheel only. But such a spring cannot keep the watch in motion. He has then joined another, whose force is to wind up the first spring eight times in every minute, and which is itself wound up but once a Vol. II.

day. To remedy the second defect, he uses a much stronger balance-spring than in a common watch. For if the force of this spring upon the balance remains the same, whilst the force of the other varies, the error arising from that variation will be less, as the fixed force is the greater. But a stronger spring will require either a heavier or a larger balance, and must have a greater friction. Mr. Harrison, therefore, increases the diameter of it. In a common watch it is under an inch, but in Mr. Harrison's, two inches and ten tenths. However, the method already used little lessened the errors, and not removing them, Mr. Harrison uses two ways to make the times of the vibrations equal, though the arches may be unequal: one is to place a pin so that the balance-spring pressing against it, has its force increased, but increased less when the vibrations are larger: the other, to give the pallets such a shape, that the wheel may press them with less advantage when the vibrations are less but great advantage when the vibrations are greater. The method by which he achieves this, is to make the balance a different part of the spring in different degrees of heat, and lengthen or shorten it as the regulator does in a common watch.

The principles on which Mr. Arnold's timekeeper is constructed are these: The balance is unconnected with the wheel-work, except at the time it receives the impulse to make it continue its motion, which is only whilst it vibrates 10° out of 360°, which is the whole vibration; and during this small interval it has little or no friction, which is on the pivots, which work in ruby holes on diamonds. It has but one pallet, which is a planet surface formed out of a ruby, and has no oil on it. Watches of this construction, in the hands of Mr. Pelletier, of Lyons, go with great accuracy, and do not require any oiling; they keep the same rate of going in every position, and are not affected by the different forces of the spring; and the compensation for heat and cold is absolutely adjustable.

TIN, a metal known to the ancients: the physicians procured it from Spain and Britain, with which nations they carried on a very extensive and lucrative commerce. This metal has a fine white colour, like silver; a slight disagreeable taste, and emits a peculiar smell when rubbed. Its specific gravity is 7.29. It is very malleable. Tin-laf or foil is about 3/10th part of an inch thick, and it might be reduced to half this thickness. It is very flexible, and produces a remarkable cracking noise when bent, and the white heat. When exposed to the air it very soon loses its lustre, and assumes a greyish-white colour, but undergoes no further change. Neither is it sensibly altered by being kept under water, but when it is made to pass over red-hot tin, it is decomposed, the tin is oxidized, and hydrogen gas is evolved.

When tin is melted in an open vessel, its surface becomes very soon covered with a grey powder, which is an oxide of the metal. If the heat be continued, the colour of the powder gradually changes, and at least it becomes yellowish. In this state it is known by the name of putty, and employed in polishing glass and other hard bodies. When tin is heated very violently in an open vessel, it takes fire, and is converted into a fine white oxide, which may be obtained in crystals.

Tin is capable of combining with two different proportions of oxygen, and of forming two oxides; usually distinguished, on account of their colour, by the names of the yellow and the white oxide. The protoxide may be obtained by exposing tin to a strong heat under a bell-jar, constantly stirring it with a rod. It may be procured also by dissolving tin in dilute sulphuric acid without the assistance of heat, and then precipitating the oxide by pure potash; but in that case it retains a little acid, and has a white colour. It is composed of about 20 parts of oxygen and 80 of tin.

Tin oxide may be obtained by heating tin in concentrated nitric acid. A violent effervescence ensues, and the whole of the tin is converted into a white powder, which is deposited at the bottom of the vessel. It is composed of about 22 parts of oxygen and 72 of tin.

Tin combines with sulphur and phosphorus; but it has never been combined with carbon or hydrogen.

Sulphuric oxide of tin may be formed by throwing on the surface of the metal melted in a crucible, or by fusing the two ingredients together. It is brittle, heavier than tin, and not so fusible. It is of a bluish and lamellated structure, and is capable of crystallizing. According to Bergman, it is composed of 80 parts of tin and 20 of sulphur; according to Pelletier, of 85 parts of tin and 15 of sulphur.

When equal parts of white oxide of tin and phosphorus are mixed together and heated gradually in a retort, some sulphur and phosphorus are disengaged; and there remains a substance composed of tin, 60 of oxygen and 60 of white oxide of tin, formerly called aurum mithrum, musicum, or mosaicum, and now sulphurized oxide of tin. It consists of beautiful gold-coloured flakes, exceedingly light, which adhere to the sides of the vessel in which the substance was formerly very complicated. Pelletier first demonstrated its real composition, and was hence enabled to make many important improvements in the manner of manufacturing it.

Phosphorus of tin may be formed by melting in a crucible equal parts of filings of tin and phosphoric glass. Tin has a greater affinity for oxygen than phosphorus has. Part of the metal therefore combines with the oxygen of the glass during the fusion, and leaves off in the state of an oxide, and the rest of the tin combines with the phosphorus. The phosphorus of tin may be cut with a knife; it extends under the hammer, but separates in laminae. When newly cut, it has the colour of silver; its filings re-semble those of lead. When these filings are thrown on burning coals, the phosphorus in takes fire. This phosphorus may likewise be formed by dropping phosphorus gradually into melted tin. According to Pelletier, whose experiments we are indebted for the knowledge of all the phosphorus, it is composed of about
85 parts of tin and 15 of phosphorus. Marggraf also formed this phospshur, but he was ignorant of its composition.

Tin does not combine with azote or mur-"mous; though the last substance converts it into an oxide.

Tin is capable of combining with most of the metals, and some of its alloys are much employed. The greater number of them and divided. The older metallurgists considered it as a property of tin to render other metals brittle. Hence they called it diabolous metallorum.

1. It mixes readily with gold by fusion; but the proportions in which these metals combine chemically are still unknown. When one part of tin and twelve of gold are melted together, the alloy is brittle, hard, and hard-colored. Twenty-four parts of gold and one of tin produce a pale-colored alloy, harder than gold, but possessed of considerable ductility. Gold alloyed with no more than \( \frac{1}{4} \) of tin is scarcely altered in its properties, according to Mr. Alchome; but Mr. Tillet, who more later examined this alloy, found that whenever it was heated it broke into a number of pieces. It is very difficult to separate these metals from each other. The method is to fuse the alloy with sulphuret of antimony.

2. Before alloy of platinum and tin is very fusible and brittle, at least when these metals are mixed in equal proportions. Twelve parts of tin and one of platinum form an alloy, possessed considerable ductility, which becomes yellow when exposed to the air.

3. The alloy of silver and tin is very brittle, hard, and durable. The two metals can scarcely be separated again by the usual processes. This alloy has been applied to no use.

4. Mercury dissolves tin very readily cold; and these metals may be combined in any proportion by pouring mercury into melted tin. The amalgam of tin, when composed of three parts of mercury and one of tin, crystallizes in the form of cubes, according to Daubenton; but, according to Sage, in gray brilliant square plates, thin towards the edges, and thick towards the center. Each of the cavities between them are polygonal. It is used to silver the backs of glass mirrors. See FOLIATION of looking-glasses.

5. Tin unites very readily with copper, and forms an alloy exceedingly useful for a great variety of purposes. Of this alloy canons are made; bell-metal; bronze; and the mirrors of telescopes, are formed of different proportions of the same metals. The addition of tin diminishes the ductility of copper, and increases its hardness, tenacity, fusibility, and sonorosity. The specific gravity of the alloy is greater than the mean density of the two metals. It appears, from the experiments of Mr. Bricke, that this augmentation of density increases with the tin; and that the specific gravity, when the alloy contains 100 parts of copper and 16 of tin, is a maximum: it is 8.87. The specific gravity of equal parts of tin and copper is 8.76, but it ought only to be 8; consequently the density is increased 0.79. In order to mix the two metals exactly, they ought to be kept a long time in fusion, and constantly stirred, otherwise the greater part of the copper will sink to the bottom, and the greater part of the tin rise to the surface; and there will be formed two different alloys; one composed of a great proportion of copper combined with a small quantity of tin, the other of a great proportion of tin alloyed with a small quantity of copper.

Bronze and the metal of canons are composed of from 6 to 12 parts of tin combined with 100 parts of copper. This alloy is brittle, yellow, heavier than copper, and has much more tenacity; it is much more fusible and less altered by exposure to the air. It was this alloy which the ancients used for sharp-edged instruments before the method of working iron was brought to perfection. The spekloos of the Greeks, and perecho, were tin. Even their copper coins contain a mixture of tin.

Bell-metal is usually composed of three parts of copper and one part of tin. Its color is greyish-white; it is very hard, sonorous, and clastic. The greater part of the tin may be separated by melting the alloy, and then pouring a little water on it. The tin decomposes the water, is oxidized, and thrown upon the surface.

The mirrors of telescopes are formed by melting together the parts of tin and one part of copper. This alloy is very hard, of the color of steel, and admits of a fine polish. But besides this there are many other compounds used for the same purpose.

Vessels of copper, especially when used as kitchen-utensils, are usually covered with a thin coat of tin, to prevent the copper from oxidizing, and to preserve the food which is prepared in them from being mixed with any of that poisonous metal. These vessels are then said to be tinned. Their interior surface is scraped very clean with an iron instrument, and rubbed over with sal ammoniac. The vessel is then heated, and a little pitch thrown into it, and allowed to spread on the surface. Then a bit of tin is applied all over the hot copper, which instantly assumes a silvery whiteness. The intention of the previous steps of the process is, to have the surface of the copper perfectly bare and mealy, enter which cannot combine with the oxide of copper. The coat of tin thus applied is exceedingly thin. Bayen ascerlentiate, that a pan nine inches in diameter, and three inches three lines in depth, when tinned, only acquires an additional weight of 21 grains. Nor is there any method of making the coat thicker. More tin indeed may be applied; but a moderate heat melts it, and causes it to run off.

6. Tin does not combine readily with iron. An alloy, however, may be formed, by fusing them in a close crucible, completely covered from the external air. We are indebted to Bergman for the most precise experiments on this alloy. When the two metals were fused together, he always obtained two distinct alloys; the first composed of 21 parts of tin and one part of iron; the second of two parts of iron and one of tin. The first was very malleable, harder than tin, and not so brilliant; the second but moderately malleable, and too hard to yield to the knife.

The formation of tin-plate is a sufficient proof of the affinity between these two metals. This very useful alloy is formed by dipping into melted tin thin plates of iron, thoroughly cleaned by rubbing them with sand, and then sleeping them 24 hours in water scalded by bran or sulphuric acid. The tin not only covers the surface of the iron, but penetrates it completely, and gives the whole a white colour. See TINNIN.

The affinities of tin, and its oxides, are, according to Bergman, as follows:

- Tin.
- Oxide of tin.
- Zinc.
- Tartaric acid.
- Mercury.
- Muratic.
- Copper.
- Sulphure.
- Antimony.
- Oxalic.
- Gold.
- Arsenic.
- Silver.
- Phosphoric.
- Lead.
- Nitric.
- Iron.
- Succinic.
- Manganese.
- Fluoric.
- Nickel.
- Sulfur.
- Arsenic.
- Citric.
- Platinum.
- Lacetic.
- Bismuth.
- Acetic.
- Cobalt.
- Boracic.
- Sulphur.
- Prussian.

Tin-plate, an ore of tin which occurs in masses and is usually covered with a metallic crystallized. These crystals are very irregular. Colour dark brown; sometimes yellowish grey, and some times nearly white. Sometimes transparent when crystallized. Specific gravity 0.9 to 0.97. Before the bloom is removed, and on charcoal is partly reduced. Tinges borax white. According to Klaproth it is composed of

- 77.50 tin
- 21.50 oxygen
- .75 iron
- .75 silica

100.00

TINCTURE. See PHARMACY.

TINCTURE, in heraldry, the hue or colour of any thing in coat-armour. See HERALD.

TINEA. See MEDICINE.

TINNIN. Tinning is the art of covering any metal with a thin coating of tin. Copper and iron are the metals most commonly tinned. The use of tinning these metals is, to prevent them from being corroded by rust; as tin is not so easily acted upon by the air or water, as iron and copper are.

What are commonly called tin-plates, sheets, so much used for utensils of various kinds, are in fact iron plates coated with tin.

The principal circumstance in the art of tinning is, to have the surfaces of the metal to be tinned perfectly clean and free from rust, and also that the melted tin may be perfectly metallic, and not covered with any ashes or cals of tin.

TINNIN. Tinning. When iron plates are to be tinned, they are first scoured, and then put into what is called a pickle, which is sulphuric acid diluted with water; this dissolves the rust of oxide that was left after scouring, and renders the surface perfectly clean. They are then again washed and scoured. They are now dipped into a vessel full of melted tin, the surface of which is covered with round pieces, and renders the action of the air. By this means, the iron coming in contact with the melted tin in a perfectly metallic state, it comes out completely coated.
When a small quantity of iron only is to be used, it is heated, and the tin rubbed on to a piece of it; or more conveniently, the scale or spangles which are sprinkled the iron with some powdered tin, the use of which is to reduce the tin at may be oxidized. Any inflammable substance, as off for instance, will have in some degree the same effect, which is owing to its attraction for oxygen.

Tinning of copper. Sheets of copper may be tinned in the same manner as iron, copper boilers, saucepans, and other kitchen utensils, are tinned after they are made. They are first scoured, then made hot, and the tin rubbed on as before with resin, nothing ought to be used for this purpose but pure grain tin; but lead is frequently fixed with the tin, both to ablate its impurity, and to make it lie on more easily; but it is a very pernicious practice, and ought to be severely prohited.

To whiten brass or copper by boiling. Put a brass or copper into a pipkin with some lime tartar, alum, and grain tin, and boil them together. The vessels will soon be covered with a coating of tin, which, when well polished, will look like silver. It is in this manner that pins, and many sorts of tins, are whitened.

TINNITUS ALÆRUM, a noise or buzzing in the ear, when it seems to receive sounds which do not exist, or at least which are not produced by the motion of the external air; but the ear being filled with a certain species of sound, cannot admit other sounds, unless they are very violent. The tinnitus is of two kinds, the one proceeding from a distemper of the organ of hearing, the other from a disorder of the brain.

TIPHIA, a genus of insects of the order Mecoptera. The generic character is, mouth clefted over by the upper jaw extended from the head; palpi two, recurved, longer than the head; pterous, very thin. The larger kinds of tipulæ are, in general, stigniæ by their lengthened bodies, horizontally expanded wings, and the unusual length and slenderness of their legs, which are also remarkably difficult to catch, and so to enable the insect without breaking some of its limbs. The smaller kind have incumbent wings, and in habit or general appearance are much alluded to gnats, and some are so very small as scarcely covered the tenth of an inch in length. The larvæ of this genus differ in habit, according to their different modes of life, some being terrestrial, and others aquatic. They feed on the softer kinds of vegetable substances, as the fine fibres of roots, &c.

The larvæ of the European tipulæ, is the pulica or Lucanus, often measuring more than an inch and a half in body; and is distinguished by the short legs, which are transparent, with large dusky indentations intermixed with white towards the rib or upper edge. This insect proceeds from a dusky or greyish larva of a lengthened form, and des-

TITANUM, a metal found in black sand, resembling guncpowder, in Cornwall, and upon examination, is found to possess the following properties: Its colour is orange-red, and it has a good deal of lustre. As it has been only obtained in very small agglomerated grains, neither its hardness, specific gravity, nor malleability, has been ascertained. It is one of the most infusible of metals, requiring a greater heat to melt it than can be produced by any method at present known.

When heated, in the open air, it combines readily with oxygen, and seems capable of existing in three different oxides; namely, the blue or purple, the red, and the white.

The protoxide, which is of a blue or purple colour, is formed, when titanium is exposed hot to the open air, evidently in consequence of the absorption of oxygen.

The deutoxide or red oxide is found native. It is often crystallized in four-sided prisms. Its specific gravity is about 4.2; and it is hard enough to scratch glass. When heated it becomes brown, and when burned by a very violent fire some of it is volatilized. When heated sufficiently along with charcoal, it is reduced to the metallic state.

The peroxy or white oxide may be obtained by fusing the red oxide in a crucible with four times its weight of potash, and dissolving the whole in water. A white powder is precipitated, which is decomposed by the acid of titanium. Vauquelin and Hecht have shown that it is composed of 89 parts of red oxide and 11 parts of water.

Titanium does not seem to be capable of combining with sulphur.

Phosphates of titanium have been formed by Mr. Chenex by the following process: He put a mixture of charcoal, phosphat of titanium (phosphoric acid combined with oxide of titanium), and a little borax, into a durable crucible, well tuted, and exposed it to the heat of a forge. A gentle heat was first applied, which was gradually raised for three quarters of an hour, and maintained for half an hour as high as possible. The phosphat of titanium was found in the crucible in the form of a metallic button. It is of a white colour, brittle, and granular, and does not melt before the blowpipe.

Vauquelin and Hecht attempted to combine it with silver, copper, and zinc, without success. But they combined it with iron, and formed an alloy of a grey colour, interpersed with yellow-coloured brilliant particles. This alloy they were not able to fuse.

The affinity of the oxides of titanium are,
according to professor Lampadius, as fol-
los. 64. Gallic acid, Sulphuric, Phosphoric, Muratic, Arsenic, Nitric, Oxalic, Acetic.

TITLES, are the tenth part of the increase yearly arising and reposing from the profits of lands, the stock upon lands, and the per-
sonal industry of the inhabitants. And hence they are usually divided into three kinds: pradial, mixed, and personal.

Pradial titles are such as arise merely and immediately from the ground, as grain of all sorts, hay, wood, fruits, herbs; for a piece of land or ground, being called in Latin praedium, whether it is arable, meadow, or pasture, the fruit or produce thereof is called pradial, and consequently the title payable for such annual produce is called a pradial title.

Mixed titles are those which arise not im-
mediately from the ground, but from things immediately nourished from the ground: as by means of cattle depastured thereof, or otherwise nourished with the fruits; as colts, calves, lambs, chickens, milk, cheese, eggs.

Personal titles are such as arise from the labour and industry of man, employing himself in some personal work, artifice, or negotiation; being the tenth part of the clear gain, after charges deducted. Watts, c. 59. But while the tithe is paid in England, except by especial custom.

Tithes with respect to value, are divided into great and small. Great tithes are, corn, hay, milk. Small tithes are the pradial tithes of all other kinds, together with those that are mixed, and personal.

Tithes of common right belong to that church, within the precincts of whose parish they arise. But one person may prescribe to have tithes within the parish of another; and this is what is called a portion of tithes.

No title is due to the mere produce of a mine, or of a quarry, because this is not a fruit of the earth, renewing annually; but is the substance of the earth, and has been perhaps so for a great number of years. 1 Rol. Abr. 637.

But in some places tithes are due by cus-
tion of the produce of mines. 2 Vern. 36.

No title is due of lime: the chalk of which this is made being part of the soil. 1 Rol. Abr. 637.

Tithes is not due of bricks which are made from the earth itself. 2 Mod. 77.

Nor is tithe due of turf, or of gravel; be-
cause both these are part of the soil. 1 Mod. 35.

It has been held, that no title is due of salt, because this does not renew annually. 1 Rol. Abr. 642.

But every one of these, and all things of the kind, may by custom become tithe.

1 Rol. Abr. 642.

Barren land converted into tillage: no tithe shall be paid for the first seven years; but if it is not barren in its own nature, as if it is fertile, garnished and made fit for tillage, tithes shall be paid presently; for woodland is fertile, not barren. 1 Rol. Abr.

Glebe lands, in the hands of the parson, shall not pay tithe to the vicar, nor being in the hands of the vicar, shall they pay tithe to the parson, because the church shall not pay tithes to the church. But if the parson lets his recarty, reserving the glebe lands, he shall pay the tithes thereof to the lessee. Gisb. 651.

No tithes are due for houses; for tithes are only due of such things as are renewed from year to year. 11 Rol. Rep. 16. But houses in London and in the next year, no tithe for such land; because by this lying fresh, the title of the next crop of corn is increased. 1 Rol. Rep. 642. But if suffered to lie fallow longer than by the course of husbandry is usual, an agriment title is due for the heads depa-
tured upon such land. Sheep. Abr. 1098.

Sheep, after paying tithe of wool, had been fed upon tumps not severed, by which they were bettered to the value of five shilling each, and were then sold; it also appeared, that before the next shearing time, as many as had been bought in as were sold, and that some of this wool of wool had been paid. It was held, that if an agriment was to be paid for the sheep sold, it would be a double tithe; and the court held, that this was a new increase, and decreed the defendant to account for an agriment title. Gibs. Rep. in E. 231. But in a later case the court held, that no agriment title should be paid on any sheep if the sheep were animalis fructuosa. Busby 278.

Corn. It is held that no tithe is due of the raking of corn involuntarily scattered. Cro. Eliz. 173. But if more of any sort of corn be. scattered, then there would have been scattered if proper care had been taken, tithe is due of the raking of such corn. Cro. Eliz. 473. No tithes are due of the stubbles left in corn-fields, after mowing or reaping of corn. 2 Rol. Abr. 641.

Tithe of hay is to be paid, though beasts of the plough or pail, or sheep, are to be foddered with such hay. 12 Mod. 197. But no tithe is due of hay upon the heads or ploughed grounds, provided that such heat lands are not wider than is sufficient to turn the plough and horses upon. 1 Rol. Abr. 646. It is laid down in an old case, that if a man cuts down grass, and while it is in the swaths carry it away, and gives it to his plough-cow, that not having sufficient for their support, otherwise, no tithe is due thereof. 1 Rol. Abr. 645. And in a modern case, the cause of exchequer was of opinion, that no tithe is due of vetches, or of clover, cut green and given to cattle in husbandry. Rainh. 279.

Wood. Tithes of wood is not due in com-
mon right, because wood does not renew itself annually; but it was in antient times paid in many places by custom. 2 Inst. 645. Fag-
got wood, however, pays tithe.

Exemptions from tithe are of two kinds either to be wholly exempted from paying any tithes, or from paying tithe in kind. The forser is called de non decadendo; the latter de modo decadendo.

Privy tithe of non decadendo, is to be free from the payment of tithes, without an recompence for the same. Concerning which the general rule is, that no layman can pro-
scribe in non decadendo; that is, to be de-
charged absolutely, from the payment of tithes and to pay nothing in lieu thereof; unless he begins his prescription in a religious or ecclesi-
astical person. But all spiritual persons, in bishops, deans, prebendaries, parsons, and vicars, may prescribe generally in non deca-
dando. 1 Rol. Abr. 653.
A modus decimandus, usually called by the name of modus only, is where there is by custom a particular manner of tithing, different from the general laws of taking tithes in kind. This is sometimes a pecuniary or money payment, as in the case of the tithe of land; sometimes a compensation in work and labour; as that the parson shall have only the twelfth cock of hay, and not the tenth, in consideration of the owner's making for him; sometimes in lieu of a large quantity, when arrived to great maturity; as a couple of fowls in lieu of tithes, &c. Any means in short, whereby the general law of tithing is altered, and a new method of taking them is introduced, is called modus decimandus, or special method of tithing. 2 Black. 29.

In order to make a modus or prescription good, several qualifications are requisite. It must be supposed to have had a reasonable commencement; as that at the time of the prescription, the thing titheable was the real value of money, though now become much less. It must be something for the parson's benefit; therefore the finding straw for the body of the church, the finding a rope for a bell, or pulling a cart, have been adjudged not to be good. But it is a good modus to be discharged, that one has time out of mind been used to employ the profits for the repair of the church, for the parson has a benefit by that.

A modus must be certain; so a prescription to pay a penny or thereabouts, for every acre of land, is void for the uncertainty. And it has been held, that if a precise day of payment is not certain, the modus will not. And now it is held, that where an amensal modus has been paid, and no certain day for the payment thereof is limited, the same shall be due and payable on the last day of the year.

A modus must be antient; and therefore if it is any thing near the value of the tithe, it will be supposed to be of late commencement, and for that reason will be set aside.

A modus must be durable: for the tithe in kind, being an inheritance certain, the prescription for it should be as durable; therefore a certain sum, to be paid by the inhabitants of such a house, has been set aside, because the house may go down and none inhabit it.

And it must be constant and uninterrupted; for if there have been frequent interruptions, no custom or prescription can be obtained. But after it has been once duly obtained, a disturbance for ten or twenty years shall not destroy it.

When a common is divided and inclosed, a modus shall only extend to such tithes as the common yielded before inclosure, and not to the tithes of hay and corn, which the common, whilst it was common, did never produce. 1635.

The parson cannot come himself and set out his tithe without the consent of the owner, as may attend and see it set out; yet the owner is not obliged to give him notice when he intends to set it out, unless by special custom. 1 Ed. 1891. After it is set out, the care thereof as to waste or spoliating rests on the parson, and not upon the owner of the land; but the parson may spread, dry, and prepare his corn, hay, or the like, in any convenient place upon the ground, till it is sufficiently weathered, and fit to be carried into the barn. And he may carry his tithe from the ground, either by the common way, or such other way as the owner of the land uses to carry away his nine parts. If the parson suffers his tithe to stay too long upon the land, the other may detain the same as doing damage, or he may have an action on the tithe, and he cannot put in his cattle and destroy the corn or other title, for that would be to make himself judge what shall be deemed a convenient time for taking it away. Lord Baym. 180.

Payment of tithes. By 1 Geo. I. c. 6, all customary payments due to clergyman, the payment of tithes, &c. are enforced; and the prosecution in this case may be for any tithes or church-rates, or any customary or other rights, dues, or payments, belonging to any church or chapel, which, of right, by law and custom ought to be paid for the stipend or maintenance of any minister or curate, officiating in any church or chapel, provided that the same does not exceed 20l. But the time is not limited, within which the same shall become enforceable.

And if any quaker shall refuse to pay or compound for the same, any parson, vicar, curate, farmer, or proprietor of such tithes, or any churchwarden, chapelwarden, or other person who has or is supposed to have, receive, or collect any such tithes, rates, dues, or payments, may make complaint to any two justices, other than such as is patron of the church or chapel, or interested in the tithes. And by of certain days not limited between the time of refusal and the complaint; nor is it hereby required that such complaint shall be in writing. But it will be more conformable to the usual practice in like cases, if it is in writing. Upon which complaint, the said justices are required to summon in writing, under their hands and seals, by reasonable warning, such quaker, against whom such complaint shall be made. And after appearance, or otherwise, as the justice shall direct, the said justice or the clerk, or any other person, administrator of the estate, or executor of the will of the person who had the tithes, or the executor of the vendor or purchaser of the estate, may direct and appoint the payment thereof, so that the sum, ordered as aforesaid, does not exceed 10l.; and also such costs and charges, that upon the merits of the case shall appear, not exceeding 10s.; and on refusal to pay, any one of the two next justices, by warrant under his hand and seal, may levy the same by distress and sale, rendering the overplus, the necessary charges of distressing being first deducted and allowed by the said justice, unless it is in the case of appeal, and then no warrant of distress shall be granted till the appeal shall be determined. Tithes under the value of 40l. may also be recovered by the same process from persons who are not quakers. As no time is limited for obtaining the distress, nor charges allowed for keeping it, it may be sold immediately.

Any person who shall think himself aggrieved by the judgment shall have an appeal to the next session; where if the judgment shall be affirmed, they shall decree the same by order of session, and give costs against the appellant, to be levied by distress and sale, as to them shall seem reasonable; and no proceeding herein shall be removed by certiorari, or otherwise, unless the title of such tithes shall be in question.

The withholding of tithes from the parson or vicar, whether the former is a clergyman or lay-appropriator, is among the primary causes cognizable in the ecclesiastical court; but herein a distinction must be taken: for the ecclesiastical courts have no jurisdiction to try the right of tithes, unless between spiritual persons, between spiritual and temporal, and are only required to settle the payment of them when the right is not disputed. 2 Inst. 364.

Tithes, however, if of any considerable value, are generally sued for in the exchequer by English bill, except where the title is not in the church with the stipulated grace of the tithe, or, if others, unless the title of such tithes shall be in question.

TITHINGMEN. In the Saxon times, for the better conservation of peace, and the more easy administration of justice, every hundred was divided into ten tithings, called tenchings or ten tithings. Each tithing consisted of ten triforbs, or triforbs of ten families; in which tithingmen, or civil deans, were to examine and determine all smaller differences between villages and neighbours, but to refer all greater matters to the superiors, which had a jurisdiction over the whole hundred.

TITLE, in law, denotes any right which a person as to the possession of a thing; or an authentic instrument, whereby he can prove his right. See RIGHT, &c.

As to the titles of the clergy, they denote certain places wherein they may exercise their functions. There are several reasons why a church is called titular; but that which seems to be the best, is because antiently the name of the same was in the church, and thereto the clergyman was an engraver on the porch, as a sign that the saint had a title to that church, and thence the church itself was afterwards called titular. In this sense a title signifies the church to which a bishop was presented, and where he is constantly to reside; and by the canons, none shall be ordained without a title. This is in order to keep out from such the ministry who, for want of maintenance, might bring a disturbance into the church. Can. 31.

In short, according to some writers, such a title is an assurance of being preferred to an ecclesiastical benefice; that is to say, a certificate that the clerk is provided of some church or vicarage, or where the bishop that ordains him, intends shortly to admit him to a benefice or curacy then void.

TITMOUSE. See PARUS.

TMESIS, in grammar, a figure whereby a compound word is separated into two parts, and one or more words placed between them; thus, for quiresque, Virgil says, quae mihi venit ex tantum terras, &c.

TOAD. See RANA.

TOBACCO. See NICOTIANA.

TODUS, the tody, in ornithology, a genus belonging to the order of passerines. The beak is slender, depressed, broad, and the base beset with bristles; the nostrils are small and oval; the toes are placed three before and one behind; the middle are connected to the outer. There are 15 species according to

Dr. Latham. * Birds of this genus (says
that eminent ornithologist) inhabit the warmer parts of America. They vary considerably in their bills, length of beak, and all of them have a certain flattening or depressions, which is peculiar. They have a great affinity to the flycatchers; and, indeed, to speak the truth, the two genera run much into one another. However, in one thing they differ materially; for in the tody, the outer and middle toes are much connected, whereas in the flycatcher genus they are divided to their origin."

BOUNDARY, the balsam of tallow-tree, a genus of plants, and the class deciduous, and order monogynia. The calyx is five-toothed, bell-shaped; petals five, obovate; style none. There is only one species, the balsamum. This tree grows to a considerable height; it sends off numerous large branches, and is covered with a large bark; the leaves are elliptical or ovate, entire, pointed, alternate, of a light-green colour, and stand upon short strong stalks; the flowers are numerous, and produced in lateral racemes.

It grows in Spanish America, in the province of Tolou, behind Carthagena, where we are supplied with the balsam. This balsam is obtained by making incisions in the bark of the tree, and the exudation is collected into spoons, which are made of black wax, from which it is poured into proper vessels.

This balsam is of a reddish-yellow colour, transparent, in consistence thick and tenacious. By age it grows hard and thick, and finally, that it may be rubbed into a powder between the finger and thumb. Its smell is extremely fragrant, somewhat resembling that of lemon. It is taste, in warm and sweetish, and on being chewed, it adheres to the teeth. See PARAS.

This balsam possesses the same general virtues with the balsam of Gilead, and that of Peru. It is, however, less heating and stimulating, and may therefore be employed with more safety. It has been chiefly used as a pectoral, and is said to be an efficacious corroboration in glects and seminal weakness. It is a perfect medicine, as Pharmacopoeia in the syrups totulanum, tintura totulanum, and syrupus balsamicus.

TOMATORE, a metal composed of copper and arsenic. See ARSEN.

TOMATE, a genus of the class and order dodecandria monogynia. The involute is four or five-leaved; calyx none; corolla five-petalled; nect. scales five; berry one-seeded. There are three species, of which the saffire or tallow-tree of China is the most remarkable. The leaves and twigs of this tree abound in a viscous juice, and being bruised and macerated in water, render it glutinous, and it is used by the natives to work up their plaster. A small quantity of thick white oil is extracted from the berries, of which candles are made resembling wax or spermaceti.

TONIC weight, 20 hundred. See WEIGHT.

TONE, or TUNE, in music, a property of sound whereby it comes under the relation of grave and acute; or it is the degree of elevation any sound has, from the degree of swiftness of the vibrations of the parts of sonorous bodies. See SOUND.

TONGUE. See ANATOMY.

TONNAGE, a custom or impost due for merchandise brought or carried in tows from or to other nations after a certain rate in every ton.

The usual method of finding the tonnage of any ship is by the following rule:—Multiply the length of the keel by the breadth of the beam; and that product by half the breadth of the boat; and divide the last product by 94, and the quotient will be the tonnage.

Ship's keel 72 feet; breadth of beam 24 feet.

\[ 72 \times 24 \times 12 \div 94 = 120.6 \text{ tonnage.} \]

The tonnage of goods and store is taken sometimes by weight, and sometimes by measurement; and that is allowed to the vessel which yields the most tonnage. In tonnage by weight, 20 cwt. make 1 ton. In tonnage by measurement, 46 cubic feet are equal to the weight of one hundredweight; all other stores to be measured by tonnage, are taken to pieces, and packed in the manner which will occupy the least room on board ship. All ordinance, whether brass or iron, is taken in tonnage by its actual weight. Musket-cartridges are reckoned in rounds or boxes, all ammunition in boxes, and other articles of great weight, are taken in tonnage according to their actual weight.

The following is the tonnage allowed to the military officers of the ordnance embarked for foreign service, for their camp-equipment and baggage:—

For a field officer = 5 tons. For a captain = 3 tons. For a subaltern = 1.5 tons.

TONSELLA, a genus of the class and order triandria monogynia. The calyx is five-parted; petals five; nect. pitcher-shaped; berry one-celled, four-seeded. There are two species, trees of the West Indies.

TONTINE. See ANATOMY.

TONTINE, in ecclesiastical history, a particular manner of administering a fund; the stock, the amount of which is fixed; while the interest arising from the stock, the amount of which is fixed; the interest arising from the stock, or the interest of the survivor, will be no more than 11. 17s. 6d. But it is to be observed, that these lives will be continually dying from the time of the first subscription to the conclusion of the tontine; and the scheme of this weekly contributions will reduce the share of each survivor to 11. 12s. nearly. When the expenses of management are also deducted, and allowance is made for the loss which may be sustained by investing the money in the public funds, it is more than probable that the shares will fall greatly below the sum just stated, and that the surviving members will, at the end of seven years, be left at and to the end of seven years, to the share of each survivor; the interest of the money they have paid, after having endangered the loss of the greatest part of it by dying in the mean time. In several of these schemes, which have lately been called by mineralogists accidental rubies, topaz, and sapphire; which, agreeing in their crystallization and most of their properties, were ar-
ranged under one species by Mr. Ronan de Lisle. The word topaz, derived from an island in the Red Sea, where the ancients used to find topazes, was applied by them to a mineral very different from ours. Our variety of our topaz they denominated chrysolite.

The topaz is found in Saxony, Bohemia, Siberia, and Brazil, mixed with other minerals in granitic rocks.

It is commonly crystallized. The primitive form of its crystals is a prism whose sides are rectangles, and bases rhombs, having their greatest angles 154° 22′, and the internal molecule has the same form; and the height of the prism is to a side of the rhomboidal bases as 3 to 2. The different varieties of topaz crystals hitherto observed, amount to 6. Five of these are eight-sided prisms, terminate by four-sided pyramids, or wedge-shaped summits, or by irregular figures of 7, 13, or 15 sides: the last variety is a twelve-sided prism, terminated by six-sided pyramids wanting the apex. For an accurate description and illustration of the varieties, the reader is referred to Mr. Hany.

The texture of the topaz is foliated. It causes a double refraction. Specific gravity from 3.45 to 3.56. The Siberian and Brazil topazes, however, become positively electrified on one side, and negatively on the other. It is insusceptible of the blowpipe. The yellow topaz of Brazil becomes red when exposed to a strong heat in a crucible; that of Saxony becomes white by the same process. This shows us that the colouring matter of these two stones is different.

The colour of the topaz is various, which has induced mineralogists to divide it into the following varieties:

1. Red topaz, of a red colour, inclining to yellow; called Brazilian or occidental ruby.
2. Yellow topaz, of a golden-yellow colour, and sometimes also nearly white; called occidental or Brazil topaz. The powder of this and the following variety, causes syrup of violets to assume a green colour.
3. Saxony topaz. It is of a pale wine yellow colour, glossy greyish white.
4. Augite marini, of a bluish or pale-green colour.
5. Occidental sapphire, of a blue colour, and sometimes white.
6. A specimen of white Saxony topaz, analyzed by Vauquelin, consisted

| 68 aluminia | 31 silica |

99.

TOPOGRAPHY, a description or draught of some particular place, or small tract of land, as that of a city or town, minor or mountain, field, garden, house, castle, &c. such as surveyors set out in their plots, or make draughts of, for the information and satisfaction of the proprietors.

TORDYLIUM, hart-wort in botany, a genus of plants of the family Compositae, and order Dignyana, and in the natural system, arranged under the 45th order, Umbellata.

The corollas are radiated, and all hermaphrodite; the fruit is roundish, and crested on the margin; the involucr long and un

There are seven species; of which two are British, the maximum and officinale.

1. The maximum, or knotted parsley, has simple sessile umbels, the exterior seeds being rough. It grows in the borders of the coasts, and in damp places.

TORMENTILLA, T. tormentil, a genus of the class Polyandria, family Polygynia, and in the natural system ranging under the 35th order, Santenum. The calyx is obovate; the petals are four; the seeds round, naked, and affixed to a juiceless receptacle. There are two species, the erecta and repens, both indigenous. The erecta, common tormentil, or sepool, has a stalk somewhat erect, and sessile leaves. The roots consist of thick tubercles, an inch or more in diameter, requiring of an assenting quality. They are used in most of the Western Islands.

TORNADO, or Tornado, a sudden and vehement gust of wind from all points of the compass, frequent on the coast of Guiana.

A tornado seems to partake much of the nature of a whirlwind or water-spout, but is more violent in its effects. It commences very suddenly, several clouds being previously drawn together, when a spot of wind, proceeding from them, strikes the ground, in a round spot of a few rods or perches diameter, in the course of the wind of the day, and proceeds thus half a mile or a mile. The prominence of its descent makes it rebound from the earth, throwing such things as are movable before it, but some sideways or in a lateral direction from it. A vapour, mist, or rain descends with it, by which the path of it is marked with vet.

The gentleman who furnishes the above general description, gives an account of one which happened a few years since at Leicester, about forty miles from Boston, in New England. "It happened in July, on a hot day; about four o'clock in the afternoon. A few clouds having gathered westward, and congealed, as is usual, in the running together in a point being observed, immediately a spot of wind struck the ground at the west end of a house, and instantly carried it away with a negro man in it, who was afterwards found dead in the path of it. Two men and a woman, by the breach of the floor, fell into the cellar; and one man was driven forcibly up into the chimney-corner. These were preserved, though much bruised; they were wet with a vapour or mist, as were the remains of the floor, and the whole path of the spot. This wind raised boards, timbers, &c. A joist was found on one end, driven near three feet into the ground. The spot probably took it in its elevated state, and drove it forcibly down. The tornado moved with the celerity of a madding wind, and constantly declined in strength till it entirely ceased."  

TORPEDO. See RAY, and ELECTRICITY.

TORRICELLIAN experiment, a famous experiment made by Torricelli, a disciple of the great Galileo, which has been already explained.

TORRID ZONE, among geographers, denotes that tract of the earth lying upon the equator, and on each side as far as the two tropics, or 23° 30′ of north and south latitude.

TORTOISE-shell, the shell of the testaceous animal called a tortoise; used in inlaying, and in various other works, as for small boxes, combs, &c. 

Mr. Catesby observes, that the hard strong covering which includes all sorts of tortoises, is very improperly called a shell; being of a perfect bony contexture, but covered on the outside with scales, or rather plates of a horny substance; which are what workmen call tortoise-shell. See HELIX.

There are two general kinds of tortoises, viz. the land and sea tortoise, testudo terrestris and marina. The sea-tortoise, again, is of several kinds; but it is the testudo imbricata of Linnaeus, alone which furnishes that beautiful shell so much admired in Europe. See Testudo.

The whole spoils of the tortoise consist in thirteen leaves or scales, eight of them flat, and five a little bent. Of the flat ones; there are four large ones, sometimes a foot long, and seven or eight inches broad. The upper shell is thick, clear, transparent, of the colour of antimony, sprinkled with brown and white. When used in marquetry, &c. the workmen give it what colour they please by means of coloured leaves, which they put underneath it.

Working and joining of tortoise-shell.—Tortoise-shell and horn become soft in a moderate heat, as that of boiling water, so as to be pressed, in a mould, into any form, the shell or horn being previously cut into plates of a proper size. Plummer informs us, in his Art de Tourner, that two plates are likewise united into one by heating and pressing them; the edges being thoroughly cleaned, and made to fit close to one another. The tortoise-shell is conveniently heated for this purpose by applying a hot iron above and beneath the juncture, with the interposition of a wet cloth to prevent the shell from being scorched by the iron. These iron should be pretty thick, that they may not lose their heat before the union is effected. Both tortoise-shell and horns may be stained of a variety of colours, by means of the colouring drugs commonly used in dyeing, and by certain metallic solutions.

TOUCAN. See RAMPHASTOS.

TOUCAN, in astronomy, a constellation of the southern hemisphere, consisting of eight small stars, and otherwise called asser americus. See ASTRONOMY.

TOUCAN, in anatomy, a constellation of the southern hemisphere, consisting of eight small stars, and otherwise called asser americanus. See ASTRONOMY.

TOUCAN, in anatomy, a constellation of the southern hemisphere, consisting of eight small stars, and otherwise called asser americus. See ASTRONOMY.

TOUCAN, in anatomy, a constellation of the southern hemisphere, consisting of eight small stars, and otherwise called asser americus. See ASTRONOMY.

TOUCAN, in anatomy, a constellation of the southern hemisphere, consisting of eight small stars, and otherwise called asser americus. See ASTRONOMY.

TOUCAN, in anatomy, a constellation of the southern hemisphere, consisting of eight small stars, and otherwise called asser americus. See ASTRONOMY.
fourth part of their breadth in thickness, and an inch and a half long; these being thus prepared are pasted on the under surface of each mark so as to give its particle, or the thinnest quirety of the admixture in it. The black rough marbles, the basaltites, or other softer kinds of black pebbles, are the most proper for touchstones.

The method of using the needles and stone is this: the piece of metal to be tried, ought first to be wiped well with a clean towel, or piece of soft leather, that you may the better see its true colour; for from this alone an expert person will, in some degree, judge beforehand what the price of metal is, and how and with what debate. Then choose a convenient, not overlarge, part of the surface of the metal, and rub it several times very hard and strongly against the touchstone; that in case a decortical coat or crust should have been laid upon it, it may be worn off by that friction: this, however, is more readily done by a grindstone, or small file, if you have them at hand. Then wipe a flat and very clean part of the touchstone, and rub against it, over and over the surface of the piece of metal, till you have, on the flat surface of the stone, a thin layer, about an inch long, and about an eighth of an inch broad; this done, look out the needle that seems most like the metal under trial, wipe the lower part of this needle very clean, and then rub it against the touchstone as you did the metal, by the side of the other line, and in a direction parallel to it. When this is done, if you find no difference between the colours of the two marks made by your needle and the metal under trial, you may, with great probability, pronounce that metal and your needle to be of the same alloy, which is immediately known by the mark engraven on your needle. But if you find a difference between the colour of the mark given by the metal, and that by the needle you have tried, choose out another needle, either of a darker or lighter colour than the former, as the difference of the tinge on the touchstone directs; and by where the marks of this kind are rubbed you would be able to determine which of your needles the metal answers, and whence it is of, by the mark of the needle; or else you will find that the alloy is extraordinary, and cannot be determined by the comparison of your needles.

TOURMALINE, in mineralogy, a species of siliceous earth. It has been found only in Ceylon, Brazil, and Tyrol. That of Ceylon is of a dark-brown of yellowish colour; its specific gravity 3.065, or 3.093; that of Brazil is green, blue, red, or yellow, and its specific gravity 3.075 or 3.180; that of Tyrol by reflected light is of a blackish brown, but by refracted light yellowish, or in thin pieces green; its specific gravity 3.050; it is readily crystallised in polygonal prisms, but sometimes amorphous. The thinnest parts are opaque: the thin more or less transparent. See Shor.

TOURNEFORTIA, a genus of the pentandra monogynia class of plants, the flowers of which consist of a single petal in form of an oval tube, longer than the calyx, divided into five slight segments somewhat broad and pointed, and spread open; the fruit is a glosso-beerry, containing two cells; and the seeds are of an oval figure, two in number, and separated by the pulp. There are eleven species, shrubs of South America. There are three species, herbs of the Levant.

TRACHICHTHYS, a genus of fishes of the order tetraclis. The generic character is, head rounded in front; eyes large; mouth wide, toothless; deciduous; gill-membrane with eight rays, the four innermost of which are rough on the edges; scales rough; abdomen crenellated with large crenate scales. There is only a single species, viz. 

TRACHINUS, a genus of fishes of the order jugulares: the generic character is, hided slightly roughened, compressed; gill-membrane six-rayed; gill-covers covered with the body compressed, vent situated near the hinder end. 1. Trachinus draco, dragon weever. This fish is of a lengthened shape, much compressed on the sides, and covered with small and hard scales, the head is wide, and opens vertically, like that of the star-gazer; both jaws are armed with sharp teeth; the tongue is straight, smooth, and pointed; the eyes are seated on the upper part of the head, but do not quite reach the gills. The gill-covers are armed at their tips with a strong spine. The general colour of the weever is silvery, with a yellowish or dusky cast on the upper parts, while the sides are commonly varied by numerous obliquely transverse streaks of a similar colour; the scales are small and rounded; the first dorsal fin is of a deep black. The usual length of the fish is about ten or twelve inches.

This fish is an inhabitant of the Mediterranean and Northern seas, commonly frequenting the coasts, and frequently infesting the sand; in which situation, if accidentally trodden on, it strikes backwards with its tail, and inflicts a violent wound on the aggressor with the spines of its first dorsal fin. So troublesome are the consequences arising from the punctures inflicted by this part, that a law is said to exist in France, obliging the fisherman to cut off the fish before the fish is exposed for sale. The usual symptoms attending the wound are, violent heat, pain, and inflammation; and it not unfrequently happens that when the hand is thus wounded, a sudden redness extends throughout the whole length of the arm, as far as the shoulder. The usual remedy among the English fishermen is, according to Mr. Pennant, sea-sand, well rubbed on the part; an application which one might at first suppose would rather aggravate than alleviate the complaint. Many other popular remedies are used in different countries. Notwithstanding the suspicious aspect of the above-mentioned black fin, it does not seem to have any thing in its constitution which can justify the idea of any poisonous fluid conveyed from it into the wound; the spines when microscopically examined shewing no apparent trace of a tubular passage.
TRADE.

In 1794 £16,729,403

1795 13,335,213

1796 19,102,290

1797 16,093,103

1798 16,672,503

1799 24,984,213

1800 25,308,000

1801 25,993,129

1802 26,093,129

1803 22,352,027

1804 23,955,793

1805 23,903,308

The real value of British produce and manufactures exported, however, considerably exceeds the above official statement, and as far as it can be ascertained, under the ad valorem duties, or computed at the average current prices of the goods, it amounted in the year 1804 to 40,349,642l. and in 1805 to 41,008,942l. The commodities included under the term British produce, such as alum, bark, coals, cattle, fish, hemp, metals, salt, and a few other articles, being united in these accounts with manufactured goods, the actual value of the latter cannot be derived from them; but in a comparative view they furnish a sufficiently accurate idea of the proportions exported at different periods.

The annual produce of the different manufactures of this country, and the employment by them, has in several instances been greatly over-rated. It is very difficult to say what the number of persons which the various branches have at different times been represented to employ, were added together, they would form a very considerable population of the country far exceed its known amount, with full allowance whatever for other occupations.

The woollen-manufacture, which is the most antient and important, has increased during the last twenty years, and appears to be still increasing, notwithstanding the high price of the material, and the precarious state of the foreign markets. On a late examination of the principal woolen-manufacturers, Mr. W. Hargiver estimated the quantity of wool grown in this country at 600,000 packs, of 240 pounds each, which at 11s. per pack makes the value of the whole 8,600,000l. He justly observed that it is difficult to ascertain how much wool is imported, and how much being manufactured; some sorts are increased rather more than double, some nine times or even more; but if the average is taken at only three times, which will be the truth, the total value of the wool manufactured in the country will amount to 19,800,000l.

It must be remarked, that this calculation is founded on a supposition that, in 1791, the number of sheep in the kingdom was 28,800,000, which, as far as any idea can be formed from the proportion of the consumption of the metropolis to that of the whole island, and the stock requisite for the supply, greatly exceeded the truth at that time; and it is the general opinion, particularly of persons in the wool-trade, that of late the number of sheep kept has been considerably reduced. The calculation is likewise made at an unusually high price of wool; for though during the year 1800, the average price of 12 to 14s. about eleven guineas, the average of the three or four preceding years was certainly not more than from ten pounds to ten guineas; upon the whole, the estimate, therefore, will be

30K
The average value of woolen goods exported from Great Britain in six years was as follows:

In 1794 £4,300,920
1795 £3,172,884
1796 £6,011,133
1797 £4,936,355
1798 £4,490,339
1799 £6,876,939

The average is £5,647,924. Most of the custom-house values of goods exported are greatly below their present value, but not so much, so in this article as in some others; they are found, however, to be about thirty-eight per cent. below the actual value, and this addition being made to the average amount, the value of woolen goods exported will appear to be £7,744,140. The value re- mained for home consumption may be nearly equal to the value exported, although in quantity the former may greatly exceed the latter; a very considerable proportion of which consists of superfine and second cloths, whereas the consumption of fine woollens in great Britain has much diminished of late years, from the general use of Manchester manufactures of cotton in clothing, particularly for workmen and hand work, and the whole value of the manufacture thus appears to be about 15,588,000l. and, as a medium between this sum and the amount before stated, it may be taken at 16,400,000l. Deducing from this amount the rate of 10 per cent. on the cost of the goods for the profits of the manufacturer, including the interest of his capital, there remains 14,909,000l. consisting of the cost of the material, and the wages of labour; the value of all the wool used, as we have seen, is about 5,750,000l. and including the cost of some other necessary articles, the materials cannot be valued at less than this sum; the remainder therefore, or 9,159,000l. will be the wages of the whole persons employed in the manufacture. It is scarcely possible to assume with precision an average rate of wages, with respect to any manufacturer, as they vary in different parts of the country, and the proportion of the different classes of persons employed is in no instance known with certainty. In the West, where the woollen-manufacture has been for some time past in a state of depression, few workmen get above 14s. per week, and many much less from being only employed; in Yorkshire good workmen earn from 16s. to 18s. per week, children 3s. older children and women from 5s. to 9s. and older men from 9s. to 12s. If, on taking all classes together, 8s. per week is not thought too high, it will appear that the whole number of persons employed does not exceed 440,340.

The value of the feather-manufacture was, some years ago, stated at 10,500,000l. and from the state of the trade of late, particularly those branches of it which supply military accoutrements, harness, saddlery, carriages, &c. combined with the high price of skins of most kinds, it cannot be supposed less than that sum at present. Deducing 934,545l. for the profits of capital employed, and 3,500,000l. for the cost of the raw article, there remains 6,045,354l. for the wages of the persons employed, at 25s. per annum for each person, makes the number employed 241,818.

The cotton-manufacture was formerly of little importance in this country, in comparison with its present state. The total quantity of cotton-wool imported into England, on an average of five years, ending with 1795, was 1,170,881 pounds, and even so late as the year 1791, it amounted to only 5,101,920 pounds. About that time, however, the British calicoes, which had been introduced some years before, had arrived at some degree of perfection, and the branch of muslins being added, in which great improvements were soon after made, the whole manufac- ture experienced a rapid and great increase, that previous to the commencement of the war with France, the consumption of cotton-wool amounted to upwards of 35,000,000l. For the price below the ten per cent. is laid on, it is proba- bly not less than this rate on the whole of this and in most other manufactures. The number of persons employed in the silk-manufac- ture has been about 100,000 and upwards, but there appears no reason to believe that it exceeds 65,000 of all descriptions.

The linen-manufacture of great Britain is chiefly carried on in Ireland, though some branches of it are carried on in Manchester and other parts of England. The exportation of British-made linen duty-free, was allowed in 1717, but the bounties on exportation were not limited till 1743, in which year the export was 52,772 yards. On an average of seven years of peace from 1740 to 155, the export of British-manufactory had increased to 270,733 yards; and it continued to increase greatly during the succeeding years, till the average of seven years, ending with 1792, was 1,336,640 yards.

The average of the next seven years was 2,423,378 yards; but in consequence of the commercial embarrassments of the year 1794, the quantity fell very much, and in the beginning of 1774, it is said there were not so much as half the weavers employed throughout Scotland and the north of England. In the course of a few years revived again, and in the year 1783 the export amounted to no less than 14,298,000 yards. The total quantity of British linen exported during three years ending with 1779, was as follows:

1776 14,533,000 yards
1778 20,744,000
1779 21,204,000

The value, estimated at the current price of linen exported, on an average of three years preceding 5th January 1798, was 1,278,734l.; therefore, if the quantity retained for home consumption is not greater than the export, the value of the whole must be upwards of 2,590,000l. and it probably will not be less. The whole value of this branch of the manufacture in Great Britain with the thread, and other branches of the flax trade, is stated at 3,000,000l. That is not of less extent, may be presumed from the following account of the quantities of
high flax and linen-yarn imported on an average of five years, ending the 3rd of January in the years stated, viz.

The annual value of the iron-manufacture was estimated at 8,700,000/.; which sum appears rather too high at present; but including tin and lead, the value of the whole will probably not be taken too high at 10,000,000/. The number of persons employed at 200,000.

The copper and brass manufactures are now established in this country in all their branches. Till about the years 1720 or 1730, most of the copper and brass utensils for culinary and other purposes, used in this country, were imported from Hamburgh and Holland, being procured from the manufactories of Germany; even so late as the year 1773, copper pots, kettles, saucepans, and pots of all sizes, were imported here in large quantities; but through the persevering industry, capital, and enterprising spirit of our miners and manufacturers, these imports have become totally unnecessary, the articles being now all made here, and far better than any other country can produce.

The discovery of new copper-mines in Cornwall, Derbyshire, and Wales, about the year 1773, has greatly added to the manufacture of this country; and it appears to be still increasing, notwithstanding the very great advantage in the price of copper, which must certainly be attended with some disadvantage in the foreign markets. The value of wrought copper and brass exported during the year 1799 was 1,222,187.; and there is reason to believe, that the whole value of these manufactures at present is at least 3,000,000/. and the number of persons employed about 60,000.

The steel, plating, and hardware manufactures, including the toy trade, have been carried to a great extent of late years, and much in value to 4,000,000/. and the persons employed to about 70,000.

It must be confessed, that many of these estimates are unavoidably defective from the want of public documents respecting many important branches of trade; they may, however, be sufficiently accurate to shew, in a general view, the relative extent of the principal manufactures of Great Britain, viz.

There are many other manufactures, such as those of hats, horn, straw, &c., which, though of themselves of less importance than most of those above enumerated, are together of very considerable amount, and employ a great number of hands. There are likewise some, which, though not generally included among the manufactures, are certainly such in a great degree, and might, with much propriety, be classed with them.

It may be proper to observe, that those who have rated the number of persons employed in the different branches very considerably higher than is here stated, have generally included a variety of employments, as mariners, carriers, miners, &c., whereas the numbers here given are meant to include only the persons directly employed in the various transactions and operations necessary for bringing the raw materials into their finished consumable state.

**TRADE-WINDS.** See WIND.

**TRADESCANTIA.** A genus of the hexaandrous monotypic class of plants, the flower of which consists of three orbiculate, plane, and very pellucid petals; and its fruit is an oval trilocular capsule, containing a few angular seeds; 10 species.

**TRAGACANTH.** See ASTRAGALUS.

Tragacanth, gum, or, as some call it, gundragon, or gum dragons, is the produce of the above and some other shrubs. The gum is brought to us in long and slender pieces, of rather a flat figure, more or less, and they are usually heavy, of a firm consistence, and properly esteemed, very tough rather than hard: and is extremely difficult to powder, and is first carefully dried, and the mortar and pestle kept dry. Its natural colour is a pale yellow, and in the clearest pieces it is something transparent. It is often, however, met with tinged brownish, and of other colours, and more opaque. It has no smell, and very little taste, but what it has is disagreeable. Taken into the mouth, it does not grow clammy, and stick to the teeth, as the gun arabic does, but melts into a kind of very soft mucilage. It dissolves in water but slowly, and communicates its mucilaginous affinity to a great quantity of that fluid. It is by no means soluble in oily or spirituous liquids, nor is it inflammable. It is brought to us from the island of Crete, and from several parts of Asia. It is to be chosen in long twisted pieces, of a whitish colour, very clear, and free from all other colours; the brown, and particularly the black, are to be rejected.

Tragacanth has the same virtues with gum.
arabic, but in a greater degree. It greatly
insipiates and obtunds the acrimony of the
humours, and is therefore found of service in
inverteous cathers, and other disorders of the
breast, arising from an acid phlegm, and in
stomach, in the cases of ulcer, and other com-
plaints of that kind. It is usually given in
the compound powder, called the species dis-
tragacanthi frigida, rarely alone. It is also.
by some, esteemed a very great external con-
trary for wounds, and in this sense made an
ingredient in some sympathetic powders, with
vitriol and other things. It is by some re-
commended alone, in form of a powder or
strong mucilage, for cracks and chaps in the
nipples of women: but it is found, by ex-
perience, to be a very troublesome application
in those cases, and to do more harm than good,
as it dries by the heat of the part, and draws
the lips of the wound further asunder than be-
fore.

TRAGIDAD. See Poetry.

TRAGIA, a genus of the monocoe trian-
dria class of plants, without any flowers—petales;
it's fruit is a very large tricocc double-cap of a
roundish figure, containing single and round-
ish, or compound. There are 8 species.

TRAGOPOGON, goat's-beard, a genus of
plants of the class syngeasia, and the or-
der polygona equals; and in the natural
system ranging under the 49th order, com-
parative. The root, and its leaves, are
purplish, the calyx simple, and the pappus plumeous.
There are 14 species; of which two are British, the
pratensis and portuloid. 1. The pratensis,
or yellow goat's-beard, has its calyxes equal
with the root and its leaves all entire, long,
marrow, sessile, and grassy. In fair weather
this plant opens at sunrise, and shuts be-
tween nine and ten in the morning. The roots
are comical and excetant, and are sometimes
boiled and served up at table as asparagus.
It grows on meadows. 2. The portuloid,
or purple goat's-beard, has the calyx longer
than the radius of the floret; the flowers are
large, purple, single, and terminal; and the
leaves are long, broad, and oblong.

TRAJECTORY, a term often used, gen-
ernally for the path of any body moving
either in a void, or in a medium that resists
its motion; or even for any curve passing
through a given number of points. Thus
Newton, Princip. lib. 1, prob. 23, purposes to
describe a trajectory that shall pass through
two given points.

Trajectory of a conic, is its path or
orbit, or the line it describes in its motion. This
path, Hevelius, in his Cometographia, will
leave to the naked and a right line; but Dr.
Hailey concludes it to be, as really is, a
very eccentric ellipse; though its place may
often be well computed on the supposi-
tion of its being a parabola. Newton, in
Prop. 41 of his 3d book, shows how to de-
termine the trajectory of a comet from three ob-
servations; and in his last prop. how to cor-
rect a trajectory graphically described.

TRAMEL, in mechanics, an instru-
mant used to regulate the length of a
bow, &c. One part of it consists of a cross
with two grooves at right angles; the other
is a beam carrying two pins which slide in these
grooves, and also the describing pencil. All
of the engines for turning achs are constructed
on the same principles with the trammeL:
the only difference is, that in the trammeL
the board is at rest, and the pencil moves
upon it; in the turning engine, the tool, which
supplies the place of the pencil, is at rest, and
the board is moved. See a demonstra-
tion of the chief properties of these instru-
ments by Mr. Ludlam, in the Philos. Trans.
vol. 70, p. 378, &c.

TRAMEL-NET, is a long net, where-
with to take fish by night in champain coun-
tries, much like the net used for the low
bell, both in shape, bigness, and meshes. To
use it, they spread it on the ground, so that
the method or further end, fitted with small
plumets, may be loose thereon; then the
other part being borne up by men placed at
the fore ends, it is thus trailed along the ground.
At each side are carried great blazing lights,
by which the birds are raised, and as they rise
under the net they are taken.

TRANSCENDENTAL, or TRANSCEN-
dant, something elevated or raised above
other things, which passes and transcends
the nature of other inferior things.

Transcendents, among geom-
eters, are indeterminate ones, or such as
cannot be fixed, or expressed by any constant
equation; such are all transcendental curves
which cannot be defined by any algebraic
equation, or which when expressed by an
equation, one of the terms thereof is a vari-
able quantity. Now whereas algebraists use
to assume some general letters or numbers, for
the quantity sought in these transcendental
problems. Leibniz assumes general or
undeinate equations for the lines sought;
c. e. putting x and y for the absciss and or-
dinate, the equation he uses for a line sought
is ax + by + cx + dy + ex - f = 0, &c. = 0,
by the help of which indefinite equation, he seeks
the tangent: and by comparing the result
with the given property of tangents, he finds
the value of the assumed letters, a, b, c, d, &c.
and thus deduces the equation of the line
sought.

If the comparison above-mentioned does not
proceed, he pronounces the line sought not
to be an algebraical, but a transcendental one.
This supposed, he goes on to find the species
of transcendent, which depend on the general
division or section of a ratio, or upon the logaritiam; others, upon
the arcs of a circle; and others, on
more indefinite and compound equations. He there-
fore, besides the symbols x and y, assumes a
third, as v, which denotes the transcendental
quantity; and of these three forms, a general
equation for the line sought, from which he
finds the tangent, according to the dif-
ferent methods, which succeeds even in
transcendental quantities. The result he
compares with the given properties of the
tangent, and so discovers, not only the value of
a, b, c, d, &c. but also the particular nature
of the transcendental quantity. And though
it may sometimes happen, that the several
transcendents are so to be made use of, and
of those of different natures too, one from
another; also though there are transcen-
dents of transcendentals, and a progression of
these, you may be satisfied with the
most easy and useful one; and for the most
part, may have recourse to some peculiar ar-
tifices for shortening the calculus, and re-
ducing the problem to as simple terms as may
be.

This method being applied to the business of
quadratures, or to the invention of quadratics,
in which the property of the tangent is always
given, it is minutely, not only how it may be
discovered, but how the same quadrature
may be algebraically impossible; but also,
how, when this impossibility is discovered,
a transcendental quadratrix may be found,
which is a thing not before shown. So that
the most general case, by this method, is
carried infinitely beyond the bounds to which
Vita and Des Cartes brought it; since, by
this means, a certain and general analysis is
established, which extends to all problems of
a certain degree, and consequently not
comprehended within algebraical equations.
Again, in order to manage transcendental
problems, wherever the business of tangents
or quadratures occurs, by a calculus, there is
hardly any that can be imagined shorter,
more advantageous, or more universal, than
the differential calculus, or analysis of indi-
visible and infinites.

By this method, we may explain the nature
of transcendental lines, by an equation:
y = ax + by + cx + dy + ex - f = 0,
then will y = \sqrt{x - x_0} + \sqrt{y - y_0},
and, if the ordinate of the
cycloid is y, then will y = \sqrt{x - x_0} + \sqrt{y - y_0},
which equation perfectly
expresses the relation between the ordinates x and from it all the proper-
ties of the cycloid may be demonstrated.

The analysis has been extended to
to those lines, which have hitherto been excluded;
for no other reason, but that they were thought
capable of it.

TRANSFORMATION of Equations, in alge-
bra, is the changing equations into others of
a different form, but of equal value. This opera-
tion is often necessary, to prepare equations for
an easy solution, some of the principal cases
of which are as follow: 1. The signs of the roots
of an equation are changed, viz. the positive
roots into negative, and the negative roots
into positive ones, by only changing the signs of
the odd, 4th, and all the other even terms of
the equation. Thus the roots of the equation
x^3 - 2x^2 + 4x - 3 = 0,
whereas the roots of the same equation having
only the signs of the 4th and 7 terms changed,
 zig. of x^3 - 2x^2 + 4x - 3 = 0,
are

2. To transform an equation into another
that shall have its roots greater or less than the
roots of the proposed equation by some given differ-
ence, proceed as follows: Let the proposed
equation be the cubic x^3 - ax^2 + bx - c = 0,
and let it be required to transform it into an-
other, whose roots shall be less than the roots
of this equation by some given difference d; if the
new equation must be the less, take
y = x - d, and hence x = y + d; then, in-
stead of x and its powers, substitute y + d and
its powers, and there will arise the new equa-
tion
differed by a cubic
(A) y^3 + ad^3 + 3ad^2 y + 3ady^2 + b + 3ad^2 y + 3ady^2 - c = 0;
whose roots are less than the roots of the former
equation by the difference d. If the roots of the
new equation had been required to be greater
than those of the old one, we must then have
substituted x = y - d, or x = x - d, &c.
TRANSMUTATION, in geometry, denotes the reduction or change of one figure or body into another of the same area or solidity, but of a different form; as a triangle into a square, a pyramid into a parallelepiped, &c. In the higher geometry, transmutation is used for the converting a figure into another of the same kind and order, whose respective parts rise to the same dimensions in an equation, admit of the same tangents, &c. If a rectilinear figure is to be changed into another, it is sufficient that the intersections of the lines which compose it are transferred, and the lines drawn through the same in the new figure. If the figure to be transmuted is curvilinear, the points, tangents, and other right lines by means whereof the curve line is to be defined, must be transferred.

TRANSMUTATION, among builders, denotes the piece that is framed across a double-light window.

TRANSMUTATION, among mathematicians, signifies the conversion of a continent, or a broken number fixed across, with a square whereon it slides, &c.

TRANSPORTATION, the act of conveying or carrying a thing from one place to another.

TRANSPORTATION of plants. In sending plants from one country to another, great cautions are necessary. The plants sent from a hotter country to a colder, should be always put on board during the spring of the year, that the heat of the season may be advancing as they approach the colder climates; and, on the contrary, those which are sent from a colder country to a hotter, should be sent in the beginning of winter, and packed up for a voyage, if they are such as will not bear keeping out of the earth, to have boxes with handles, filling them with earth, and planting the roots as close together as may be; the plants should be set in these boxes three weeks before they are to be put on board; and in good weather they should be set upon the decks, and in bad removed or covered with a tarpaulin. If they are going from a hotter country to a colder one, they will generally have very little moisture, so, on the contrary, they are going from a colder to a warmer, they may be allowed water more largely, and being shaded from the heat of the sun, they will come safe.

A great many plants, however, will live out of the earth a considerable while; as the sedums, euphorbias, meconopsis, thistles, &c., and other succulent ones. These need no other care than the packing them up with moss in a close box; and there should be a little hay put between, to prevent them from wounding or bruising one another, and locks bored in the boxes to keep them from heating and putrefying. In this manner they will come safe from a voyage of two or three, or even four or five months. Several trees also will come in the same manner; taking them up in the autumn when they have done growing, not packing them up with moss. Of this sort are oranges, olives, capers, jasmines, and pomegranate trees. These, and many others, are annually brought to us from the east, and, though they are three or four months in the passage, seldom miscarry. The best way of sending over seeds, is in their natural husks, in a bag, or packed up in a gourd-shell, keeping them dry, and out of the way of vermin.

TRANSPOSITION, in algebra, the bringing any term of an equation over to the other side.

TRANSUBSTANTIATION, in theology, the conversion or change of the substance of the bread and wine into the body and blood of Jesus Christ, which the Romish church hold is wrought by the consecration of the priest. This is a main point in the Romish religion, and is rejected by the protestants, the former maintaining the transubstantiation to be real, the latter only figurative; interpreting the text hoc est corpus meum, " this signifies my body?" but the council of Trent stood up strenuously for the literal sense of the verb eat, and say expressly, that in transubstantiation the body and blood of our Lord Jesus Christ are truly, really, and substantially, under the species of bread and wine. The controversy about this point has been considerable.

TRANSVERSE MUSCLES, in anatomy, are certain muscles arising from the transverse processes of the vertebrae of the loins. See Anatomy.

TRAPA, a genus of the *Tetragonia* monogynia class of plants, the corolla is hermaphrodite, consisting of four petals, two linearly placed, and larger than the cup; the fruit is a hard osseous capsule, of an oblong oval figure, containing only one cell, and armed with four sharp thick spines, placed oppositely in the middle of the sides, and pointed; these before were the leaves of the caixs: the seed is a covered single nucleus, of an oval figure. There are two species, aquatic.

TRAPEZIUM, in geometry, a plane figure containing four unequal right sides. 1. Any three sides of a trapezium taken together, are greater than the third. 2. The two diagonals of any trapezium, divide it into two proportional triangles. 3. If two sides of a trapezium are parallel, the rectangle under the aggregate of the parallel sides and one-half
their distance, is equal to that trapezium. 4. If a parallelogram circumscribes a trapezium, so that one of the sides of the parallelogram is parallel to a diagonal of the trapezium, that parallelogram will be the double of the trapezium. 5. If any trapezium has two of its opposite angles, each a right angle, and a diagonal is drawn joining those angles; and if from the other two angles are drawn two perpendiculars to that diagonal, the distance from the feet of these perpendiculars to those right angles, respectively taken, will be equal. 6. If the sides of a trapezium are each bisected, and the points of bisection are joined by four right lines, these lines will form a parallelogram, which will be one-half of the trapezium. 7. If the diagonals of a trapezium are bisected, and a right line joins these points, the aggregate of the squares of the sides is equal to the aggregate of the squares of the diagonals, together with the square of the right line joining the point of bisection. 8. In any trapezium, the aggregate of the diagonals is less than the aggregate of four right lines drawn from any point (except the intersection of the diagonals) within the figure.

TRAPS. See Rocks, primitive.

TRAVERE, or Transverse, in general, denotes something that goes athwart another; that is, crosses and cuts it obliquely.

Hence, to traverse a piece of ordnance, meaning gunners, signifies to turn or point it which way one pleases, upon the platform.

In fortification, traverse denotes a trench with a little parapet, or bank of earth, thrown perpendicularly across the mast, or other work, to prevent the enemy's cannon from raking it. These traverses may be from twelve to eighteen feet, in order to be cannon-proof; and their height about six or seven feet, or more if the place is exposed to any enemy. And to protect a communication, a passage of about five or six feet wide must be left at one end of the traverse. If any part of a work, thus shut in by one or more traverses, is likely to be defended by the musketry, it will be provided with foot-holes within the defence, for the troops to mount on when they want to fire over the traverse.

Traverse. See Navigation.

Traverse, in law, signifies sometimes to deny, sometimes to overthrow or undo a thing, or to put one to proseose matter; much used in answers to bills in chancery: or it is that which the defendant pleads or says in bar to avoid the plaintiff's bill, either as confessing and avoiding, or by denying and traversing the material parts thereof.

Traverse an Indictment, is to take issue upon the chief matter, and to contradict or deny some point of it. A traverse must be always made to the substantial part of the title. Where an act may indifferently be intended to be at one day or another, there the day is not traversable. In an action of trespass generally, the day is not material; therefore, the matter is due upon a particular day, there it is material and traversable. 2. Rolf's Rep. 37.

TRAVESTY, or Travesti, a French term, derived from the verb 'travailler', to disguise one's self, or to appear in masquerade; and hence, travesty is applied to the disfiguring of an actor, or to the translation into a different style and manner different from his own, by which means it becomes difficult to know him.

TREACLE. See Sugar, sc.

TREASON, in law, is divided into high treason and petty treason. High treason, as compared under the famous high treason act, as it is called, or the statute 25th Edw. III. is divided into seven heads.

1. When a man compasses or imagines the death of the king, queen, or the heir apparent, he is guilty of high treason. But as this compassing or imagining is an act of the mind, it cannot be proved unless demonstrated by some overt (or open) act. To conspire to imprison the king, and toassemble company for the purpose, to procure arms and ammunition with the intent to kill him, or even to take arms in order to put such designs into execution, as consulting of the best means of putting him to death, are overt or open acts.

2. To violate the queen-consort, the king's eldest daughter, or wife of the heir apparent, is high treason; and if both parties consent, they are alike guilty. This is to guard the blood royal from pollution, so that to violate a queen or princess dowager is not treason.

3. If a man levies war against the king in his realm, he is guilty of high treason. This may be done under pretence of redressing grievances, as well as to dethrone the king. An insurrection with the avowed design of destroying all inclosures, all broths, &c. is likewise treason; though a tumult to destroy any particular inclosure or brothel would only amount to a riot: but in the first instance, the universality of the design renders it high treason. A more conspiracy to level war is not treason, unless the design is particularly pointed against the king, when it falls under the first head, viz. compassing or imagining his death.

4. To be an adherent to the king's enemies in his realm, or aiding them in his realm, or otherwise, is treason. The only way by which it must be demonstrated by some overt act, as the giving them intelligence, sending provisions, surrendering up a fortress by combination with the enemy, and not by cowardice, in which case it is an offence against the laws of war, but not treason. Giving assistance to foreign pirates or robbers who invade our coasts without any open hostilities between their nation and our own, or any commission from any state at war with Great Britain; also aiding our own fellow-subjects in rebellion at home; are both treasons; but to relieve a rebel fled out of the kingdom is not. And if a person through force or fear is obliged to join the rebels, provided he leaves them at the first safe opportunity, he is not treasonable.

5. Counterfeiting the great or privy seal is likewise high treason.

6. Counterfeiting the king's money; or bringing false and counterfeit money into the realm, and knowing it to be false, uttering it, is the great crime of treason. Counterfeiting is of itself treason, without making payment with it; and if the minter alters the legal standard of gold and silver, it is treason. As to importing foreign counterfeit money, it is held that uttering it without importing it is not within the statute. The seventh and last species of treason under this statute is, if a man slays the chamberl. treasurer, or the king's justices of either of the bench, justices in eyre, or justices of assize, and all other justices assigned to hear and determine their cases during their offices. This extends only to killing them, and not to wounding and assaulting them. The barons of the exchequer are not specified as within the act, but by the 3 Edw. c. 18, and 1 W. and M. c. 21, the lord keeper or commissioners of the great seal are within it.

There are other treasons, not comprised under this act, which may be divided into three heads: 1. Such as relate to piracy. 2. Such as relate to falsifying the coin or other royal signatures. 3. Such as relate to securing the protestant succession in the house of Hanover.

For the first see Papists. For the second see Coinage.

By the statute 1 Anne, s. 2, c. 17, if any person shall endeavour to deprive or hinder any person being the next in succession to the crown, according to the limitations of the act of settlement, from succeeding to the crown, and shall commit any other overt act, such offence shall be high treason. And by statute 6 Anne, c. 7, if any person by writing or printing manifest and affirms that any person has any right or title to the crown of this kingdom, contrary to the act of settlement; or that the king of this realm, with the authority of parliament, are not able to make laws and statutes to bind the crown and the descent thereof; such person shall be guilty of high treason.

The punishment for this crime is very severe: that the criminal shall be dragged on the ground to the place of execution, though a sledge is now allowed through humanity, and be langed and cut down alive, his entrails taken out and burned before his face, his heart cut off, and his body quartered. The punishment for coining is, however, more mild.

Treason, misprision of. There is likewise a misprision of treason, which is the concealing the knowledge of treason without ascertaining to R. 1 and 2 Ph. and Mary, c. 10. The statute 13 Eliz. c. 2, enacted, that those who for foreign coins not current in Great Britain, their aids, abettors, or procurers, shall be all guilty of misprision of treason. The punishment for this crime, which is a degree lower than high treason, is loss of the profits of lands for life, forfeiture of goods, and perpetual imprisonment.

Treason, petit (which is an aggravated degree of murder), according to the statute 25th Edw. III. c. 2, may happen three ways: by a servant killing his master, a wife her husband, or an ecclesiastical person his superior to whom he owes faith and obedience: such a servant is liable to be hanged whereupon he has left upon a grave conceived while in his service; for the intention was formed while the relation subsisted: so if a wife is separated a mesne & thorowe, the vicarious matrimonii is not continued; and if her husband after the divorce, she is guilty. And a clergyman owes canonical obedience to the bishop who ordained him, to him in whose diocese...
TREESTIMATORS in found poor the men.

TREASURE, TROVE, is where any monoy or coin, gold, silver, plate, or bullion, is hidden in the earth, or other private place, the owner in which case the treasure belongs to the king, or some other who claims by the king's grant, or by prescription. Brac. Lib. 3. But if he had it known, or afterwards found out, the owner, and not the king, is entitled to it. Black. 295.

TREASURER, an officer to whom the treasure of a prince, or corporation, is committed to be disposed of.

The lord high treasurer of Great Britain, or first commissioner of the treasury when in commission, has under his charge and government all the king's revenue, which is kept in the exchequer. He holds his place during the king's pleasure, being instituted by the delivery of a white staff to him: he has the check of all the officers employed in collecting the customs and other royal revenues; and in his gift and disposition are all the officers of the customs in the several ports of the kingdom; excisors in every county are nominated by him; he also makes leases of the lands belonging to the crown. This office is now always executed by a commission, who are entitled, "the commissioners for executing the office of lord high treasurer," and the first commissioner is commonly prime minister.

There is, besides the lord treasurer, a treasurer of the king's household; who is of the privy council, and the steward of the marshalsea, has great power.

To these may be added the treasurer of the navy; as also the treasurer of the king's chamber, and of the wardrobe; and most corporations throughout the kingdom have treasurers, whose office is to receive their rents, and disburse their common expenses.

The treasurer of the county is an officer that keeps the county-stock, in which office there are two in every county; who are chosen by the major part of the justices of the peace at Easter-sessions. They ought to have the value of 150l. in land, and the income of 150l. in personal estate; and are to continue in their office only for a year, at the end whereof, or within ten days after the expiration of the year, they must account to their successors, under certain penalties. The county-stock which this officer has the keeping of, is raised by rating every parish annually; and the same is from time to time disposed of to charitable uses, towards the relief of poor offenders, prisoners in the county gaols, paying the salaries of officers of houses of correction, and relieving poor. Im-houses, &c.

TREFOIL. See Trifolium.

TREMELLA, a genus of plants of the class craspedosporosphaera, and natural order of algae. It is a gelatinous membraneous substance; the parts of the fructification scarcely visible. There are 11 species, of which five are indigenous: the nostoc, lichenoides, verrucosus, heimisphera, and purpurea. 1. The nostoc, or jelly rain tromella, is found in pastures and by the sides of gravel-walks in gardens after rains; not uncommon in spring, summer, and autumn. It is a membraneous, pellicular, and gelatinous substance, without any visible thallus; of a yellowish dull-green colour; assuming various forms, either round, angular, plated or folded together irregularly, like the intestines, or a pocket-handkerchief, an inch or two, or more, in diameter: soft to the touch when moist; but thin, membraneous, and brittle, when dry; and of a black fuscous colour. The ancient alchemists called this vegetable the flowers of heaven, and imagined that from it they should procure the universal menstruum: but all their researches ended in discovering that by distillation it yielded some phlegm, volatile salt, and empyreumatic oil. It has been extolled in wounds, ulcers, &c. but no regard is ever paid to it by judicious practitioners. Dr. Darwin says, he has been well informed that tromella is a mucilage voided by herons after they have eaten frogs. 2. The lichenoides, or transparent tromella, is erect, plane, margin curled, laminated, and brown. It grows on rocks and in woods, and is a white, membranaceous, or varie tromella, is tubercular, solid, wrinkled, roundish, and resembling a bladder; it is of a blackish yellow. It grows on stones in rivulets. 4. Hemisphera, or sea tromella, is scattered among concrevus, &c. 5. Purpurea, or purple tromella, is globular, sessile, solitary, and smooth. It grows on ditch-banks about London.

TREMOLITE. This mineral is found chiefly near St. Gothard, in Switzerland; and takes its name from mount Tremola, where it was first observed by Nannure. It occurs is massive and in crystals. The primitive form of its crystals is a rhombohedral prism, whose sides are inclined to each other at angles of 126° 59' 13" and 53° 7' 45". It usually occurs in four-sided prisms, terminated by rhombohedral summits; and not unfrequently the two acute edges, or all the four, are truncated. Texture radiated. Fragments splintery. Specific gravity from 2.9 to 3.2. Fibres easily separated, so that it appears soft, yet it scratches glass. Phosphoresces very readily when struck or rubbed in the dark. Before the blowpipe, melts into a white scoria. Werner divides this species into three sub-species.

A specimen of tremolite analysed by Klaproth, contained

- 65.0 silica
- 38.0 lime
- 0.5 magnesia
- 0.5 oxide of iron
- 6.0 water and carbonic acid

100.0

A specimen of this mineral from the castle-hill of Edinburgh, analysed by Dr. Kennedy, yielded

98.0, with some traces of magnesia and muratic acid.

Boutron has shown that the property which the tremolite has of phosphorizing when rubbed, is owing to the presence of carbonat of lime.

TREMOR. See Medicine.

TRENCHES, in a siege, are of tches made by the besiegers, that they may approach more securely to the place attacked; on which account they are also called lines of approach. The tail of the trench is the place where it was begun, and its head is the place where it ends.

Trenches are also made to guard an encampment.

The trenches are usually opened or begun in the night-time, sometimes within musket-shot, and sometimes within half or whole cannon-shot of the place. They are about 800 fathoms. They are carried on in winding lines, nearly parallel to the works, so as not to be in view of the enemy, nor exposed to the enemy's shot.

The workmen employed in the trenches are always supported by a number of troops to defend them against the sallies of the besieged. The pioneers, and other workmen sometimes work on their knees, and are usually covered with mantlets or escabiers; and the troops who support them lie flat on their faces, in order to avoid the enemy's shot. On the angles or sides of the trench, there are lodgments, or eggements, in form of traverses, the better to hinder the sallies of the garrison, and to favour the advancement of the trenches, and to sustain the workmen.

The platforms for the batteries are made behind the trenches; the first at a good distance, to be used only against the sallies of the enemy. As the approaches advance, the batteries are brought nearer, to ruin the defences of the place, and dismount the artillery of the besieged. The breach-batteries are made when the trenches are advanced near the very walls.

If there are two attacks, it will be necessary to have lines of communication, or byways, between the two, with places of arms at convenient distances. The trenches are 6 or 7 feet high with the parapet, which is 5 feet thick, with bastings for the soldiers to mount upon.

The approaches at a siege are generally carried on upon the capitals of the works attacked; because the capitals produce roof, of all other situations in the front of a work, the least exposed to the fire of either the cannon or musketry; and are the least in the line of fire between the besieged and besiegers' batteries. But if, from particular circumstances, these or other advantages do not attend the approaches upon the capitals, they are by no means to be preferred to other positions.

The trenches of communication, or zigzags, are 3 feet deep, 10 feet wide at bottom, and 13 feet at top, having a berm of one foot, beyond which the earth is thrown to form a parapet.
The parallels or places of arms of the trenches are 3 feet deep, 12 feet wide at bottom, and 17 or 18 feet from a bank in height, having a bank of about 3 feet wide, with a slope of nearly as much.

The first night of opening the trenches, the greatest exertions are made to take advantage of the enemy's ignorance as to the side of attack. The workmen are generally carried on as far in advance as the first parallel, and even sometimes to the completion of that work. The workmen set out on this duty, each with a fascine of 6 feet, a pick-ax, and a shovel; and the fascines being laid so as to tap one foot over each other, leave 5 feet of trench for each man to dig.

The usual method of directing the trenches or zig-zags, is by observing during the day some near object in line with the salient parts of the work, and which may serve as a direction in the night; or if the night is not very dark, the angles of the works may be seen above the horizon; but as both these methods are subject to uncertainty, the following is proposed: The most extended part of the attack is first laid down the plan of attack, the exact positions of the flanked angles of the works of the front attacked, and particularly of those most extended to the right and left; mark on the plans the points of commencement for the first portions of zig-zag, the point where it crosses the capital, and the point to which it extends on the other side of the capital: this last point will be the commencement of the second branch; then mark off the point where this branch crosses the capital, and its extent on the other side; and this will give the commencement of the third branch; and so on for the others. This provided with a plan ready marked of it, will be very easy, even in the darkest night, to lay down the points where the zig-zags are to cross the capital, and the points to which they are to be produced beyond them. The first parallel is generally run about 600 yards from the place, and of such extent as to embrace the prolongation of the faces of all the works which fire upon the trenches; and each end has a return of about 30 or 40 yards.

The second parallel is constructed upon the same principles, and of the same extent, as the first, at the distance of about 300 yards from the salient angles of the covert-way. This parallel is usually formed of gabions; each workman carrying a gabion, a fascine, a shovel, and a pick-ax. After this the trenches are usually carried on by sap.

The half-parallel are about 140 or 150 yards from the covert-way, and extend sufficiently on each side to embrace the prolongation of the branches of a covert-way.

The third parallel must not be nearer than 28 yards from the covert-way, or they will be liable to be annoyed by hand-grenades.

Trench, return of a, are the elbows and turnings, which form the lines of approach, and are made, as near as can be, parallel to the place, to prevent their being enfiladed.

TRENCHES, to mount, is to mount guard in the trenches, which is generally done in the night.

TRENCHES, to relieve the, is to relieve the guard of the trenches.

TRENCHES, to secure the, is to make a vigorous sally upon the guard of the trenches, force them to give way and quit their ground, drive away the workmen, break down the parapet, fill up the trench, and nail their cannon.

TRENCHES, counter, are trenches made against the besiegers; which consequently have their parapet turned against the enemy's approaches, and are enfiladed from several parts of the place, on purpose to render them useless to the enemy, if they should chance to become masters of them; but they should not be enfiladed or commanded by any height in the enemy's possession.

TRENCHES, to open the, is to break ground for the purpose of carrying on approaches towards a besieged place.

TREPPING, See SURGERY.

TREPIDATION. See Medicine.

TRESPASS, is any transgression of the law, under trespass, felon, or misprision of either. Stautd. Pl. Cor. 36.

Trespass signifies going beyond what is lawful; hence it follows that every injurious act is, in the large sense of this word, a trespass. Some trespasses are not accompanied with any force; a trespass of this sort is called a trespass upon the case: and the proper remedy for the party injured, is by an action upon the case. Other trespasses are accompanied with force, either actual or implied. If a trespass which was accompanied with either actual or implied force, has been injurious to the public, the proper remedy in every such case, is by an indictment, or by information in the case. If a trespass was accompanied with an actual force, has been injurious only to one or more private persons, the offender is in every such case liable to an indictment, or to an information; for although the injury has in such case been only done to one or more private persons, as every trespass accompanied with actual force is a breach of the peace, it is to be considered and punished as an offence against the public. 5&c. Abr. 150.

A man is answerable for not only his own trespass, but that of his cattle also. 3 Black. 211.

And the law gives the party injured, a double remedy in this case; by permitting him to detain the cattle thus doing damage, till the owner shall make him satisfaction, or else by leaving him to the common remedy by action. And in either of these cases of trespass committed on another's land, either by a man himself or his cattle, the action that lies, is the action of trespass with force and arms; for the law always couples the idea of force with that of taking possession of the property of another. 3 Black, 210.

In some cases, trespass is justifiable; or rather entry on another's land or house shall not in these cases be accounted trespass: as if a man came there to demand or pay money there payable, or to execute in a legal manner the process of the law. 3 Black 219.

For every filing such information, and actions of trespass, it is enacted by 43 Eliz. c. 6 22, and 23 Car. II. c. 9, and 3 & 9 W. c. ii. that where a jury who try an action of trespass, give less damages than 40l., the plaintiff shall recover no damages; unless the judge shall certify on the back of the record, that the freethold or title of the land came chiefly in question. But if it shall appear that the trespass was willful and malicious, the plaintiff shall have his full costs. And every trespass is willful, where the defendant has been forsworned, and malicious where the intent of the defendant appears to be to harass or injure the plaintiff. 3 Black. 570.

TRESPASSER, denotes a person that comes, or proceeds to or into any lands, in respect of whom it is held, that though the law permits a person to enter a tavern, and a landlord to distrain on lands, &c. yet if he abuses this liberty by committing any trespass, he will be judged a trespasser.

TRET, in commerce, an allowance made for the waste, or the dirt, that may be mixed with any commodity, which is always four pounds in every hundred and four pounds weight. See TARE.

TREVIA, a genus of the polyandria monogyna class of plants, having no corolla besides the cup; the fruit is a turbinate, tricuspid, coronated, trilocular, trivalvate capsule; the seed is single, convex on one side, and angular on the other. There is one species, a tree of the East Indies.

TRIAL, in law, the examination of a cause, civil or criminal, according to the laws of the land, before a proper judge; or, it is the manner and order observed in the hearing and determining of causes. There are divers kinds of trials; as those of matters of fact, which must be tried by a jury; matters of law which are only triable by the courts; and matters of record, which are to be tried by the records themselves. The practice of trials in foreign countries, where the jury are strangers to the whole matter. Where any trial is for murder, it must be in the county wherein the fact was committed; but if the assaultis in one county, and the person assailing happens to die in another county, the indictment may be found by a jury of the county where the party died; and by special commission, when a person is indicted in one county, he may be tried in another. In all criminal cases the custom is to ask the prisoner how he will be tried, which was formerly a very significant question, though it is not so now; because antiently there were trials by combat, by ordeal, and by jury; and when the prisoner answered, By God and his country, it appeared he made choice to be tried by a jury; which is the only now used way for the trial of criminals.

The method of proceeding in a criminal case is this. First the bill of indictment, against the offender is prepared, and the prosecutor and his witnesses attend on the grand jury, and there give in their evidence; which being done, the grand inquest either and the bill of indict-
ment, or bring it in ignominy; and if the bill is found, the prisoner is brought to the bar of the court, and the clerk of the arraignment calls him by his name, desires him to hold up his hand, saying, "Thou art indicted by the name—, for such a felony, &c. (setting forth the crime laid in the indictment). How sayest thou? art thou guilty of this felony whereof thou art indicted, or not guilty?" To which the prisoner answering, "Not guilty," the clerk says, "Culprit, how wilt thou be tried?" whereupon the prisoner answers, "By God and my country;" which plea of the prisoner the clerk records, and then the panel of the petty-jury is called over.

After the jury are sworn, and the indictment is read over to them, and they are charged, the evidence on both sides, for and against the prisoner, are called, sworn, and examined in open court; after which the jury bring in their verdict; and if they find the prisoner guilty, their verdict is recorded, and the prisoner is taken from the bar; but if they bring him in not guilty, the prisoner is discharged.

On the prisoner being brought in guilty, proclamation is made for all persons to keep silence, upon which the prisoner is again brought, and the arraignment repeated; after which sentence is passed on him, and an order or warrant is made for his execution.

The methods of trial, in our civil courts, are as follows: viz. The declaration is first drawn for the plaintiff, and when the appearance of the defendant is entered, it has been usual to deliver it with an imprecation to the defendant's attorney; and the term following, rule is to be given with the secondary for the defendant to plead by such a day, or else the plaintiff is to have judgment: and the defendant having pleaded, a copy of the issue made by the plaintiff, and delivered to the defendant's attorney, at the same time giving him notice of the trial; in which the record is made up, and the parties proceed to answer and defend, and the judge gives in their verdict, &c. But in case the defendant neglects to plead, and suffers it to go by default, on entering such a judgment, a writ of inquiry of damages is awarded returnable next term, notice of the execution whereof the defendant's attorney is to have; and which being executed, and the damages inserted in a schedule annexed to the writ, a rule is given, and costs are taxed by the prothonotary.

TRIANDRIA, in the Linnean system of botany, a class of plants, the third in order; comprehending all such plants as have hermaphrodite flowers, with three stamens, or male parts, in each; whence the name. See Botany.

TRIANGLE, in geometry, a figure bounded or contained by three lines or sides, and which consequently has three angles, from whence the figure takes its name.

Triangles are either plane, or spherical, or conoid. In plane geometry the three sides of the triangle are right lines; but spherical when some or all of them are arcs of great circles on the sphere.

Plane triangles take several denominations,

Vol. II.

both from the relation of their angles, and of their sides, as below. See Geometry.

The chief properties of squares of triangles are as follow, viz. In any plane triangle,

1. The greatest side is opposite to the greatest angle, and the least side to the least angle, &c. Also, if two sides are equal, their opposite angles are equal; and if the triangle is equilateral, or has all its sides equal, it will also be equiangular, or have all its angles equal to one another. 2. Any side of a triangle is less than the sum, but greater than the difference, of the other two sides.

3. The sum of all the angles of a triangle, when taken together, is equal to two right angles. 4. If one side of a triangle is produced, the external angle, made by it and the adjacent side, is equal to the sum of the two opposite internal angles. 5. A line drawn parallel to one side of a triangle, cuts the other two sides proportionally, the corresponding segments being proportional, each to each, and to the whole sides; and the triangle cut off is similar to the whole triangle.

If a perpendicular is let fall from any angle of a triangle, as a vertical angle, upon the opposite side as a base; then, 6. The rectangle of the sum and difference of the sides, is equal to twice the rectangle of the base and the difference of the sides, separated from the middle of the base. Or, which is the same thing in other words, 7. The difference of the squares of the sides, is equal to the difference of the squares of the segments of the base; or, as the base is to the sum of the sides, so is the difference of the sides to the difference of the segments of the base.

8. The rectangle of the legs or sides is equal to the rectangle of the perpendicular and the diameter of the circumscribing circle.

If a line is drawn bisecting any angle, to the base or opposite side; then, 9. The segments of the base, made by the line bisecting the opposite angle, are proportional to the sides adjacent to them. 10. The square of the line bisecting the angle, is equal to half the difference of the angles at the base. Or, as the base is to the sum of the sides, so is the difference of the segments of the base to the rectangle of the segments of the base.

If a line is drawn from any angle to the middle of the opposite side, or bisecting the base, then, 11. The sum of the squares of the sides of the triangle, is equal to the square of half the base and the line bisecting the base. 12. The angle made by the perpendicular from any angle and the line drawn from the same angle to the middle of the base, is equal to half the difference of the angles at the base.

13. If through any point within a triangle three lines are drawn parallel to the three sides of the triangle, the continual products of any solids made by the alternate segments of these lines will be equal. 14. If three lines are drawn from the three angles of a triangle to bisect the opposite sides, or to the middle of the opposite sides, do all intersect one another in the same point, and that point is the centre of gravity of the triangle; and the difference of the squares of any angle is equal to the double the distance from the opposite side, or one segment of any of these lines is double the other segment: moreover the sum of the squares of the three bisecting lines is 1 of the sum of the squares of the three sides of the triangle.

15. Three perpendiculars drawn from the three sides of a triangle, all intersect in one point, and that point is the centre of the circumscribing circle. 17. Three lines bisecting the three angles of a triangle, all intersect in one point, and that point is the centre of the inscribed circle. 18. Three perpendiculars drawn from the three angles of a triangle upon the opposite sides, all intersect in one point. 19. Any triangle may have a circle circumscribed about it, or touching all its angles, and a circle inscribed within it, or touching all its sides. 20. The square of the side of an equilateral triangle is equal to three times the square of the radius of its circumscribing circle.

21. If the angles of one triangle are equal to the three angles of another triangle, each to each, then those two triangles are similar, and their like sides are proportional to one another, and the areas of the two triangles are to each other as the squares of their like sides.

22. If two triangles have any three parts of the one (except the three angles) equal to three corresponding parts of the other, each to each, those two triangles are not only similar, but also identical, or having all the corresponding parts equal, and their areas equal.

23. Triangles standing upon the same base, and between the same parallels, are equal; and triangles upon equal bases, and having equal altitudes, are equal. Triangles upon equal bases, are to one another as their altitudes, and triangles of equal altitudes are to one another as their bases; also equal triangles have their bases and altitudes reciprocally proportional.

24. Any triangle is equal to half its circumscribing parallelogram; or half the parallelogram on the same or an equal base, and of the same or equal altitude.

25. The area of any triangle is found by multiplying the base by the altitude, and taking half the product.

27. The area is also found thus: Multiply any two sides together, and multiply the product by the sine of the opposite angle, to radius 1 and divided by 2. 28. The area of an obtuse triangle is otherwise found thus, when the three sides are given: Add the three sides together, and take half their sum; then from this half sum subtract each side severally, and multiply the three remainders equal to one another, and finally together; then the square root of the last product will be the area of the triangle.

29. In a right-angled triangle, if a perpendicular is let fall from the right angle upon the hypotenuse, it will divide it into two other triangles similar to one another, and to the whole triangle.

30. In a right-angled triangle, the square of the hypotenuse is equal to the sum of the squares of the two sides; and, in general, any figure described upon the hypotenuse is equal to the sum of two similar figures described upon the two sides.

31. In an isosceles triangle, if a line is drawn from the vertex to any point in the base, the square of that line, together with the rectangle of the segments of the base, is equal to the square of the side.

32. If one angle of a triangle is equal to 120°, the square of the base will be equal to the sum of the squares of both the sides, together with the square of the altitude; and if those sides are equal to each other, then the square of the base will be equal to three times the square of one side, or equal to twice times the square of the perpendicular.
The teeth of the walrus are used as ivory; but on this subject antiquirs seem to vary considerably; some representing them as superior to common ivory, and others greatly inferior, and more subject to turn yellow. The animal is very generally killed for the sake of the oil; and it is said that a very strong and elastic liquor may be prepared from the skin. See Plate Nat. Hist. fig. 404.

2. Trichechus dugong, Indian walrus. This species is a native of the seas about the Cape of Good Hope and the Philippine Islands. It does not, however, seem to be very clearly known to naturalists. The grinders differ from those of the walrus, being broader in proportion: of these there are four on each side, and the lower ones are large, of which the lower is said to be of a sharper or narrower form. This species, in the Philippine Islands, is said to be called by the name of dugong.

3. Trichechus boricalis, manatee or whale-tailed trichechus. This animal seems to approach so nearly to the dugong or whale tribe, as scarcely to deserve, according to Mr. Pennant, the name even of a fishes; what are called the feet being little more than pectoral fins, which serve only for swimming, and are never used to assist the animal either in walking or landing; for it never goes ashore, nor ever attempts to climb the rocks like the walrus and the seal. It brings forth in the water, and, like the whale, suckles its young in that element. Like the whale, it is also destitute of voice; and has also a horizontal tail, which is broad, and of the form of a crescent, without even rudiments of hind feet.

So complete is the account given by Mr. Pennant of this animal, that we shall here deliver the most material parts of that author's description, rather than attempt a new one. It inhabits the seas about Bering's and the other Aleutian islands, which intervene between Kamtschatka and America, but now appears to have been reduced to a few individuals, as is supposed by a tempest. It is probably the same species which is found above Minhalo, but is certainly that which inhabits near Rodriguez, as it is called Diego Reys, an island to the west of Mauritius, or near, which it is likewise found. It is also probable that it extends to New Holland. They live perpetually in the water, and frequent the edges of the shores; and, in calm weather, swim in great flocks near the mouths of rivers: in the time of flood they come to near the land that a person may stroke them with his hand: if hurt, they swim out to the sea, but presently return again. They live in families, one near another; each consists of a male, a female, a half-grown young one, and a very small one. The females obligé the young to swim before them, while the other old ones surround, and, in a manner, guard them on all sides. The affection between the male and female is very great; for if she is attacked, he will defend her to the utmost; and if she is killed, will follow her corpse to the very shore, and swim for some days near the place it has been landed at.

They are vastly voracious, and feed not only on the thick grass that grow in the sea, but such as are flung on the edges of the shore. When
they are filled, they fall asleep on their backs. During their meals they are so intent on their food, that any one may go among them, and choose which he likes best. Their back and sides are generally above water; and numerous gills of various sizes, on each side of their backs, in order to pick the insects which they find upon them.

They continue in the Kamtschatkan and American seas the whole year; but in winter they are very lean, so that one may count their ribs. They are taken by harpoons and driven to a strong cord; and after they are struck, it requires the force of thirty men to draw them on shore. Sometimes, when they are transversed, they will lay hold of the rocks with their paws, and stick so fast as to leave the skin behind before they can be forced off. When a man is struck, its companions swim to its assistance: some will attempt to overturn the boat, by getting under it; others will press down the rope, in order to break it; and others will strike at the harpoon with their tails, with a view of getting it out, in which they often succeed. They have no voice—a noisy, hard breathing, like the snorting of a horse.

They are of an enormous size: some are twenty-eight feet long, and eight thousand pounds weight: but, if the Miammoo species is the same with this, it decreases in size as it advances southward, for the largest which Damper saw there weighed only six hundred pounds. The head, in proportion to the bulk of the animal, is small, oblong, and almost square; the nostrils are filled with short bristles; the gills are small; the lips are double; near the junction of the two jaws the mouth is full of white tubular bristles, which serve the same purpose as the laminae in whales, to prevent the food from running out with the water: the lips are also full of bristles, which serve instead of teeth to cut the strong roots of sea-plants, which, floating ashore, are a sign of the vicinity of these animals, in the mouth are no teeth; only two flat white teeth, like a jaw, can always be found below, with unsalinated surfaces, which serve instead of grinders.

The eyes are extremely small, not larger than those of a sheep: instead of ears are only two minute orifices, which will scarcely permit a quill to enter. The spines on the tail are short; the neck thick, and its junction with the head scarcely distinguishable; and the last always hangs down.

The circumference of the body near the shoulders is twelve feet; about the belly twenty; near the tail only four feet eight inches: the head thirty-three inches: the neck near seven feet: and from these measurements may be collected the deformity of the animal. Near the shoulders are two feet, or rather fins, which are only two feet two inches long, and have neither fin nor tail; nor, indeed, concave, and covered with hard bristles; the tail is thick, strong, and horizontal, ending in a stiff black fin, and like the substance of whalebone, being much split on the fore part and behind. Both ends are of equal length like the whale.

The skin is very thick, hard, and black; full of inequalities, like the bark of oak; so hard as scarcely to be cut with an ax, and has no hair upon it: beneath the skin is a thick blubber, which is said to taste like oil of almonds. The flesh is coarser than beef, and will not soon putrify: the young ones taste like veal: the skin is used for shoes, and for covering the sides of boats. The Russians call this animal morskaia korovka or sea-cow, and kapung, an animal of pale brown, variegated with spots of a deeper cast. It is native of the Indian seas, and is said to possess a degree of electrical power. There are only these two species.

TRICHOZA, a genus of vernex infrusoria. The generic character is, a worm invisible, pediculid, hairy or hoary. Amebae of this genus, which is very numerous, will be found in Adams's work on the Microscope. See Plate Nat. Hist. fig. 406. There are about sixty species.

TRICOCEPHALUS, a genus of vernex intestina. The generic character is, body round, elastic, and variously twisted; head or fore part much thicker, and furnished with a slender exsertile proboscis; tail or posterior part long, capillary, and terminating to a fine point. There are six species: T. hominis, see Plate Nat. Hist. fig. 405, inhabits the intestines of sickly children, generally the cecum, and in considerable numbers; about two inches long and resembling the ascidians in coloration. The other species are known from animals on which they live, as the equi, apri, mus, vulpis, and lacerata.

TRICHILLA, a genus of the class and order decadraria monogynia. The calyx is mostly five-toothed; petals five; nectarinum toothed; capsules three-celled, three-valved; seeds bearded. There are 12 species, trees chiefly of the West Indies.

TRICHIOPUS, a genus of the class and order polycandra digynia. The calyx is four or five parted; corolla styles two, bifid; capsulae bistris, four-valved, many-seeded. This is one species, a tree of Guiana.

TRICHOMANES, a genus of plants of the class cryptogamia, and order filices. The parts of fructification are solitary; and terminated by a little like a bristle at the edge of the leaf. There are 27 species; of which two are natives of Britain, the pithiferum and tunbrigum. 1. Pithiferum, or cupricharum, has subpinnated leaves, the pinnas being alternate, close, and serrate. It is found among stones in wet grounds in England. 2. Tunbrigum, or Tunbridge tri- chomanes, has pinnated leaves, the pinnas being oblong, dichotomous, decurrent, and dentate. It is found in the fens of most rocks in Wales, and in many rocky places in Scotland.

TRICOCCELE, the name of the 36th order in Linnaeus's Fragments of a Natural Method, consisting of plants with a single three-celled capsule, having 3 cells or internal dis caduceus containing a single seed. See BOTANY.

TRICOSANTHE, a genus of plants of the class monocera, and order synge- nesia, and in the natural system ranging under the 34th order, cucubraceae. There are seven species; only one of which is cultivated in the British gardens, the aquaum or snake-gourd, which is a native of China, an annual, and of the cucumber tribe.

TRICOSTEMA, a genus of the dieldynamia gymnosperma class of plants, with
monopetalous, ringent and falcate flower.

The stamens are four extremely long filaments; and four roundish seeds are contained in the cup. There are three species.

TRIDAX, a genus of the syngenesia polygamous class of plants, with a radiated flower, and the lesser hermaphrodite ones of the disc monopetalous, and tufted-fashion.

The seeds are winged with down, and contained in the cup. There is one species.

TRIENTALIS, chickseed winter-green, a genus of the class heptandria, and order monogynia, and in the natural system ranging under the 20th order, rotacea.

The calyx is heptaphyllous; the corolla is equal and plane, and is divided into seven segments; the berry is unicellular and dry. There is only one species, the europaea, which is indigenous, and the only genus of heptandria that is so. The stalk is single, five or six inches high, terminated with five, six, or seven oval pods or corns; from the centre of which arise on long footstalks commonly two white starry flowers, each generally consisting of seven oval and equal petals, succeeded by a globular dry berry, covered with the natural system and having, one cell, and containing several angular seeds.

TRIFOLIUM, trefoil or clover, a genus of plants of the class diadelfa, and order decandria, and in the natural system ranging under the 32d order, papilionaceae. The flowers are generally in round heads; the pod is scarcely longer than the calyx, valvate, not opening, deciduous. The leaves are three together. There are 51 species; of which 17 are natives of Britain. We shall describe some of the most remarkable of these:

1. Officinal or mellot, has naked racemous pods, dispermous, wrinkly, and acute, with an erect stalk. It grows in corn-fields, and by the waysides, but not common. The stalk is erect, firm, straited, branched, and two or three feet high; the leaves tenuate, smooth, obtusely oval, and serrated; the flowers are small, yellow, pendulous, and generally in long close spikes at the tops of the branches; the pod is very short, turgid, transversely wrinkled, pendulous, and contains either one or two seeds. The plant has a very peculiar strong scent, and disagreeable, bitter, acrid taste, but such, however, as is not disagreeable to cattle. The flowers are sweet-scented. It has generally been esteemed emollient and digestive, and been used in fomentations and cataplasm, particularly in the plaster employed in dressing boils; but is now laid aside, as its quality is found to be rather acrid and irritating than emollient or resolvent. It communicates a hoarseness flavour to wheat and other grain, so as to render it unfit for making bread.

2. Trifolium repens, white creeping trefoil, or Dutch clover, has a creeping stalk, its flowers superabundant, and its pod tetraspernum. It is very common in fields and pastures. It is well known to be an excellent fodder for cattle; and the leaves are a good rustic hygrometer, as they are also a useful relish and relished in dry weather, but creet in moist or rainy.

3. Trifolium pratense, purple or red clover, is distinguished by dense spikes, unequal capsules, by bearded stipulas, ascending stalks, and by the calyx having four equal teeth. The red clover is common in meadows and pastures, and is the species which is generally cultivated as food for cattle. It abounds in every part of Europe, and is even in Siberia. It delights most in rich, moist, and snunny places, yet flourishes in dry, barren, and shady places. See HUSBANDRY.

4. Alpestrae, long-leaved purple trefoil, or mountain trefoil. The spikes are dense; the corollas somewhat equal; the stipulas are bristly and divergent; the leaflets lanceolat; the stalks still, straight, and very simple. It grows in dry, mountainous, woody places, in Hungary, Austria, and Boeotias, &c.; but is not said to be a native of Britain.

5. The medium has been confounded with the two species last mentioned; but it is to be distinguished from them by having loose spikes, corollas somewhat equal, stipulas subulate and convolute, the stalks flexuose and branched. It is found in dry elevated situations, especially among shrubs, or in woods where the soil is chalky or clay, in England, Scotland, Sweden, Denmark, &c.

TRIGLA, gurnard, a genus of fishes of the order of the ophidiiformes. The gurnard is, head large, mailed, and marked by rough lines; Gill-cover spiny; Gill-membrane seven-rayed; finger-shaped processes, in most species, near the pectoral fins.

1. Trigla gurnardus, grey gurnard. Length from one to two feet, or more; body deep grey, with blackish and red spots, beneath silvery; scales small; lateral line very strongly marked, and consisting of a series of larger, rounded, whitish scales with a dusky centre. Native of the European seas, and not uncommon about our own coasts, feeding on worms, insects, &c.

2. Trigla lyra, piper gurnard. Size nearly equal to the former species; lateral line formed of small scales; colour bright rose-red, silvered, and scales small; fins large, and slightly tinged with dull blue; tail of similar colour; the other fins yellowish, with red rays. Native of the European seas, and considered as an excellent fish for the table.

3. Trigla cuculus, cuckow gurnard. An elegant species. Length about a foot; shape more slender than in the preceding kinds; colour, on the upper parts, a beautiful red, more or less distinctly marked by white transverse bars, beneath silvery; scales exceedingly small; lateral line composed of pointed white scales edged with black; a similar row on each side the back; fins transparent; the first dorsal marked on the edge by a black spot, the second tinged near its edge with yellow. Native of the European seas, and esteemed as a food.

4. Trigla hirundo, sapphire gurnard. Size equal to that of the grey gurnard; scales minute-sized; lateral line rough; pectoral fins very large, of a violaceous olive, some times, according to Mr. Pennant, richly edged and spotted with blue. Native of the European seas, occasionally springing out of the water to some distance by means of its large pectoral fins.

5. Trigla vuls, flying gurnard. A highly singular and beautiful species. Length about twelve inches; colour crimson above, pale whitish beneath; head blunt, and armed on each side with two very strong and large spines, pointing backwards; whole body covered with extremely strong carinated and sharp-pointed scales, or furnished as not to be distinctly separable; first dorsal fin pale violet, crossed with deeper lines, and at its origin two separate rays longer than the rest; second dorsal fin pale, with the rays barred brown; pectoral fins extremely large, transparent, of an olive-green, richly variegated with numerous bright-blue spots; pectoral processes six in number, and not separate, as in other species, but united into the appearance of a small fin on each side the thorax; tail pale-violet, with the rays crossed by dusky spots, and strengthened on each side the base by two obliquely transverse bony ribs or bars. Native of the Mediterranean, Atlantic, and Indian seas, where it swims in shoals, and is often seen flying out of the water to a considerable distance, in the manner of the genus exocetus. There are in all 14 species.

TRIGLOCHIN, a genus of plants of the class hexandria, and order trigynia, and in the natural system ranging under the fifth order, tripetaloideae. The flowers are heptaphyllous; the petals are three; there is no style; the capsule opens at the base. There are three species, of which the palustre and maritimus are British.

1. Palustre, or arrow-headed grass, has an oblong trilocular capsule. The stalk is simple, eight or ten inches high; the leaves long and narrow; the flowers are greenish, and grow at the end of a long spike. It is frequent in moist grounds.

2. Maritimus, or sea-spiked grass, has ovate seilocular capsules; the stalk is short; the spike long, and flowers purplish. It is frequent on the sea-coasts. Linnaeus says that cattle eat these two species with avidity.

TRIGONELLA, fenugreek, a genus of plants of the class diadelfa, and order decandria, in the natural system arranged under the 32d order, papilionaceae. The vexillum and ala are nearly equal and patent, resembling a tripetaloid corolla. There are 12 species, of which the most remarkable is Trigonoella linifolia, a native of Montelpier, in France. Fenugreek is an annual plant, which rises with a hollow, branching, herbaceous stalk, a foot and a half long, with trifoliate leaves, placed alternately, whose lobes are oblong, oval, indented on their edges, and have broad furrowed foot-stalks. Fenugreek seeds have a strong disagreeable smell, and an unctuous farinaceous taste, accompanied with a slight bitterness. The principal use of these seeds is in cataplasm and fomentations, for softening, maturing, and discussing tumours; and in emollient and carminative elixirs. They are an ingredient in the oeleum & mucilaginis of the pharmacopoeia, not to be considered a share of their smell, but this is now in use.

TRIGONIA, a genus of the diadelfa decandria class and order of plants. The calyx is five-parted; petals five, unequal; neck; two scales at the base of the germ, slightly tinged some karzones; pedicles triquetrous, three-coriolated, three-celled, three-valved. There are two species, of Guiana.
TRIGONOMETRY is that part of geometry which teaches how to measure the sides and angles of triangles, and of the methods of determining their sides and angles. For this purpose, it is not only requisite that the peripheries of circles, but also that certain right lines in and about a circle, are supposed to be divided into some assigned number of equal parts. These lines are denominated sines, tangents, secants, etc., the sides of plane triangles, and may be estimated in feet, yards, chains, or by any other definite measures, or by abstract numbers; but the angles are measured by the arcs of a circle, as contained between the two legs, having the angular point for its centre.

Every circle is supposed to be divided into 360 equal parts, called degrees; each degree into 60 equal parts, called minutes; each minute into 60 equal parts, called seconds. An angle is said to be of as many degrees, minutes, seconds, &c., as are contained in the arc, or part of the circumference, which it is measured by. The whole circumference of a circle is measured by the fourth part of the circumference, or 90°; an obtuse angle is greater than 90°, and an acute angle is less than 90°.

The difference of an arc from 90°, or a quadrant, is called its complement, and its difference from 180°, its supplement; thus in Plate Misc.; 25°, the arc AB is the complement of HB; but AB is the supplement of BD.

A chord of an arc is a right line drawn from one extremity of an arc to the other; thus BE is the chord or subtenue of the arc BA, or BDE.

The sine of an arc is that sine, which is sometimes called, the right sine, of an arc, is a right line drawn from one extremity of the arc, perpendicular to the diameter passing through the other extremity: thus BE is the sine of the arc AB, or EB.

The versed sine of an arc is the part of the diameter, intercepted between the arc and its sine; thus AE is the versed sine of AB, and DF of the arc DB.

The cosine of an arc is the part of the diameter intercepted between the center and the sine, and is equal to the sine of the complement of that arc. Thus DF is the cosine of the arc AB, and is equal to EB, the sine of its complement HB.

The tangent of an arc is a right line touching the circle in one extremity of that arc, continued from thence to meet a line drawn from the center through the other extremity; which line is called the secant of the same arc: thus AG is the tangent, and CO the secant of the arc AB.

The co-tangent and co-secant of an arc are, the tangent and secant of the complement of that arc: thus HK and CX are the co-tangent and co-secant of the arc AB.

The line here described, belong equally to an angle as to the arc by which it is measured and, except the chords and versed sines, they are all common to two arcs or angles which are the supplements of each other.

Thus, the sine of an arc, whether by degrees, minutes, or seconds, or by any arc or angle above 90° required, is the same thing as to find the sine, tangent, &c., of its supplement, or what it wants of 180°.

They are also called the natural sines, tangents, secants, &c. of an arc or angle by which they are represented, are the logarithmic sines, tangents, &c.

And as one or other of these lines make a part of every trigonometrical operation, they have been made the basis of every degree, minute, &c., of the quadrant, and ranged in tables for use.

Whence, by the help of such a table, the sine, tangent, &c., of any arc or angle, may be found by inspection; and, vice versa:—That is, the tangent or sine of an arc, &c., may be found from the sine or tangent, &c., of that arc, or angle, to which any sine, tangent, &c., belongs.

Upon this table also, and the doctrine of similar triangles, depends the solution of the several cases of plane triangles, which may be performed either by the natural or logarithmic sines, tangents, &c., as occasion requires.

But the logarithmic sines, tangents, &c., are those most commonly used; as the calculator, in this case, are all performed by adding and subtracting only, instead of multiplying and dividing, as is required by the natural sines, &c.

The sine, tangent, &c., of any arc or angle being of the same magnitude as the sine, tangent, &c., of its supplement, it is plain that a table of these lines made for every degree, minute, &c., of the quadrant, or 90°, will serve for the whole circle.

It is also to be observed that, in every such table, the natural sines, tangents, &c., are usually calculated to radius 1; but in order that the logarithmic, sines, tangents, &c., may be all positive, they are usually calculated to radius 0.00000000, or 1 with 10 cyphers, the logarithm of which is 10, so that the latter are the logarithms of the former, with 10 added to the indices.

And, as the natural sines, tangents, &c., of any angles or arcs of different circles, are proportional to the radius of those circles, their values may be readily found, or made to correspond to any radius whatever.

In every plane triangle, three things must be given to find the rest; and of these three one at least must be a side, because the same angles are common to an infinite number of triangles.

It is also to be observed, that all the varieties that can possibly happen in the solution of plane triangles, are comprised under the following cases:—

1. When two of the three given things are a side and its opposite angle.
2. When two sides and their included angle are given.
3. When the three sides are given.

Each of which cases may be resolved, either by geometrical construction, by arithmetical computation, or instrumentally.

In the first of these methods, the triangle is constructed, by laying out the sides from a scale of equal parts, and the angles from a scale of chords, or a protractor, and then measuring the unknown parts by the same scale or instrument from which the others were taken.

In the second method, having stated the proportion, according to the proper rule, multiply the second and third terms together, and divide the product by the quotient: the angles of the first, and the number answering to the remainder will be the fourth term sought.

In the third method, or instrumentally, as the logarithms of the logarithmic lines on one side of the common two-foot scales, extend the compasses from the first term to the second or third as they happen to be of the same kind; and that will give the angle between them together, and from the same place the logarithm of the fourth term required, taking both extents towards the same end of the scale.

The second of these methods, however, or that in which the operation is performed by logarithms, is the one generally employed; the other two being chiefly of use on checks on the calculations, or, in certain cases, where a near approximate value of the quantities to be determined is thought sufficient.

It may here be also further remarked, that if a triangle be supposed to be of the first or second case, and be subtracted, in any operation, it will be better to write down their complements, or what each of them wants of 100°000000 instead of the logarithms themselves, and then add those defects, abutting as many tens in the index of the sum as there were logarithms to be subtracted.

Thus, if the logarithm to be subtracted is 6.5067249, it will be the same thing as to add its complement 0.90749900, and if it is 0.97499900, its complement, or the number to be added, will be 0.92500000; which numbers must be subtracted from the index of the sum, and subtracting each figure of the logarithm from 9, except the last significant figure on the right, which must be subtracted from 10.

If the index of the logarithm, whose complement is to be taken, is 8 7.5067273; and the complement of the logarithm of 3.979234 is 2.04257392.

PROPERTIES OF PLANE TRIANGLES, REQUIRED IN THE PRACTICAL PART OF THIS SCIENCE.

The sum of all the angles of any plane triangle is equal to two right angles, or 180°.

The greater side is opposite the greater angle; and the less side to the less angle.

The sum of any two sides is greater than the third; and if difference of any two sides is less than the third.

The triangle is equilateral, isosceles, or scalene, according as its three angles are all equal, or only two of them equal, or all three unequal.

The angles opposite to the two least sides are acute; and if there is an obtuse angle, it is opposite to the greatest side.

A perpendicular drawn from the opposite angle to the longest side will fall within the triangle; and the greater and less segment will be the greater and less side.

In an isosceles triangle, a perpendicular drawn from the vertex will bisect both the base and the vertical angle.

In a right-angled triangle the hypotenuse is equal to the square root of the sum of the squares of the other two sides; and either of the sides is equal to the square root of the difference of the squares of the hypotenuse and the other side.

Note, also, that if the half difference of any two quantities is added to their half sum, it will give the greater of those quantities; and, if it is subtracted from the half sum, it will give the less.

Case I.—When two of the three given things are a side and its opposite angle, to find the rest.

Rule. The sides of any plane triangle are to each other as the sines of their opposite angles, and vice versa:—That is, as any side is to the sine of its opposite angle, so is any other side to the sine of its opposite angle.

Or, as the sine of any angle is to its opposite side, so is the sine of any other angle to its opposite side.

Hence, to find an angle, begin the proportion with a side opposite to a given angle; and co
TRIGONOMETRY.

Instrumentally.

In the first proportion, extend the compasses from 236 to 330, upon the line of numbers, and that extent extend, upon the sines, from 38° to 47°, for the \( \angle A \).

In the second proportion, extend from 38° to 23°, or 75° upon the sines, and that extent extend, upon the numbers, from 236 or 184, for the side AB, or BC.

Example II. In the plane triangle ABC, given \( \angle B = 37^\circ 20' \), Ans. \( \angle A = 67^\circ 24' \), and \( \angle C = 124^\circ 14' \). Required the other parts.

Example III. In the plane triangle ABC, given \( \angle B = 37^\circ 20' \), Ans. \( \angle A = 67^\circ 24' \), and \( \angle C = 124^\circ 14' \). Required the other parts.

Example IV. In the plane triangle ABC, given \( \angle B = 37^\circ 20' \), Ans. \( \angle A = 67^\circ 24' \), and \( \angle C = 124^\circ 14' \). Required the other parts.

Example V. In the plane triangle ABC, given \( \angle B = 37^\circ 20' \), Ans. \( \angle A = 67^\circ 24' \), and \( \angle C = 124^\circ 14' \). Required the other parts.

Case II. When two sides and their included angle are given, to find the rest.

Rule. As the sum of any two sides of a plane triangle, is to their difference, so is the tangent of half the sum of their opposite angles, to the tangent of half their difference.

Then, the half difference of these angles, added to their half sum, gives the greater angle, and subtracted from it gives the less.

And as all the angles are now known, the remaining side may be found by Case I.

Note. Instead of the tangent of half the sum of the two unknown angles, we may use the cotangent of half the given angle, or the tangent of half its supplement, which are all equal to each other.

Example'. In any plane triangle ABC, given \( \angle B = 37^\circ 20' \), and side AC = 236. Required the rest. By Construction. 1. Draw BC = 236, by a scale of equal parts.

2. Set off the \( \angle B = 37^\circ 20' \), by a scale of chords, or other instrument.

3. Make \( \mu = 37^\circ 20' \), by the same scale of chords, as before.

4. Join AC, and the triangle is constructed.

Then, the parts being measured, we shall have \( \angle A = 124^\circ 14' \), \( \angle C = 23^\circ 28' \), and side AC = 1630 feet.

By Calculation.

\[
\begin{align*}
\angle A + \angle B &= 164^\circ 0' \quad \angle A = 124^\circ 14' \\
\angle A - \angle B &= 20^\circ 28' \quad \angle C = 23^\circ 28' \\
\angle B - \angle A &= 40^\circ 0' \quad \angle C = 1630 \text{ feet} \\
\angle C - \angle B &= 116^\circ 44' \\
\angle C - \angle A &= 16^\circ 46' \\
\angle B - \angle C &= 141^\circ 44' \\
\angle A - \angle C &= 148^\circ 46' \\
\angle B - \angle A &= 40^\circ 0' \\
\end{align*}
\]

And, in the triangle ACD, right-angled at D, given \( AC = 348 \), and \( CD = 276.75 \). Required the rest.

By Calculation.

\[
\begin{align*}
\angle A + \angle B &= 164^\circ 0' \quad \angle A = 124^\circ 14' \\
\angle A - \angle B &= 20^\circ 28' \quad \angle C = 23^\circ 28' \\
\angle B - \angle A &= 40^\circ 0' \quad \angle C = 1630 \text{ feet} \\
\angle C - \angle B &= 116^\circ 44' \\
\angle C - \angle A &= 16^\circ 46' \\
\angle B - \angle C &= 141^\circ 44' \\
\angle A - \angle C &= 148^\circ 46' \\
\angle B - \angle A &= 40^\circ 0' \\
\end{align*}
\]

This three problems include all the cases or varieties of plane triangles, as well right-angled as oblique, that can possibly happen; but there are some other theorems, for right-angled triangles, that are often more convenient in practice than the general one, the most useful of which is that one which follows.

Case IV. In any right-angled triangle, as ABD is to BCD, so is the tangent of either of the acute angles, to the side adjacent to that angle, to the side opposite to it; and vice versa.
The Solution of the Cases of Oblique Plane Triangles, fig. 294.

TRIGONOMETRY.

Or, as radius is to the cotangent of either of the acute angles, so is the side opposite to that angle, to the side adjacent to it; and vice versa.

It may also be observed, that the sine of either of the acute angles of a right-angled triangle, being equal to the cosine of the other, the latter may be used instead of the former, whenever it renders the operation more simple.

Example I. In any right-angled plane triangle ABC, Required the other parts.

By Construction. Make BC = 294, and \( \angle B = 58^\circ 7' 46'' \) parts.

Then raise the perpendicular CA, meeting BA in A; and the triangle is constructed; in which AB will be found to measure 294, and AC 412; and \( \angle A \), which is the complement of \( \angle B \), is \( 96^\circ 18' \).

By Calculation:

1. \( \text{Rad. or sine} \times 99^\circ = 10.000000 \)
2. Tan, \( \angle B = 58^\circ 7' 46'' \) = 10.1299371
3. Side BC = 294
4. Side AC = 412
5. \( \text{Sine} \times \text{ complement of} \angle B = 9.7781594 \)
6. Side BC = 294
7. \( \text{Rad. or sine} \times \angle C = 90^\circ = 10.000000 \)
8. Side AC = 412
9. \( \text{Sine} \times \text{complement of} \angle A = 2.6835921 \)

And \( 58^\circ 7' 46'' = 36^\circ 59' 12'' \) \( \angle A \).

We shall now give in a tabular form, (1) The solution of the cases of right-angled plane triangles; and (2) The solution of the cases of oblique plane triangles.

The Solution of the Case of right-angled plane Triangles, fig. 294.

Spherical trigonometry. Spherical trigonometry is the art whereby, from three given parts of a spherical triangle, we discover the rest; and, like plane trigonometry, it is either right-angled or oblique-angled. But before we give the analogies for the solution of the several cases of each, it will be proper to premise the following theorems:

Theorem I. In all right-angled spherical triangles, the acute angles, the sides opposite to them, and the angle between the other sides, are equal.

The same thing is true of the sides of these triangles.

Theorem II. In any right-angled spherical triangle, the sine of one of the acute angles is equal to the tangent of the other acute angle.

Theorem III. In any right-angled spherical triangle, the sine of one of the acute angles is equal to the tangent of the other acute angle.

Theorem IV. In any right-angled spherical triangle, the sine of one of the acute angles is equal to the tangent of the other acute angle.

Theorem V. In any right-angled spherical triangle, the sine of one of the acute angles is equal to the tangent of the other acute angle.

Theorem VI. In any right-angled spherical triangle, the sine of one of the acute angles is equal to the tangent of the other acute angle.

The following propositions and remarks, concerning spherical triangles (selected and communicated to Dr. Hutton by the reverend Nevil Maskelyne, D. Astronomer-royal, F. R. S), will also render a correct solution of them picturesque, and free from ambiguity.

1. A spherical triangle is equilateral, isocosceles, or scalene, according as it has three angles all equal, or two of them equal, or all three unequal; and vice versa.

2. The greatest side is always opposite the
TRIGONOMETRY.

The Solution of the Cases of right-angled Spherical Triangles (fig. 252.).

Note: The 10th, 11th, and 12th cases are ambiguous; since it cannot be determined by the data, whether ABC, and AC, are greater or less than 90° each.

In any spherical triangle, the area, or surface inclosed by its three sides upon the surface of the globe, will be found by the proportion:

As 8 right angles, or 720°,
Are to the whole surface of the sphere;
Or, as 2 right angles, or 180°,
To one great circle of the sphere;
So is the excess of the 3 angles above 2 right angles,
* To the area of the spherical triangle.

Hence, if \( d \) denotes .7854,
\[ d = \text{diam. of the globe, and} \]
\[ z = \text{sum of the 3 angles of the triangle;} \]
then \[ \frac{\text{add} \times \frac{z}{180}}{180} = \text{area of the spherical triangle.} \]

Hence also, if \( r \) denotes the radius of the sphere, and \( s \) its circumference; then the area of the triangle will thus be variously expressed:

**TRIGUERA,** a genus of the pentandria monogyne class and order of plants. The corolla is bell-shaped; nect. short; berry four-celled, two seeds in each cell. There are two species, of no note.

**TRILLIATAE,** from triv., "three," and halyon, "an external mark on the seed," the name of the 23rd class in Linnaeus's Fragments of a Natural Method; consisting of plants
with three seeds, which are marked with an external cecid of scar, where they are fastened within the fruit. See Botany.

TRILIX, a genus of the class and order polyandra monogynia. The calyx is three-lobed and corolla three-petalled; berry five-celled, many seeded. There is one species, a shrub of Curtangina.

TRILLION, in arithmetic, a billion of a billion.

TRILLIUM, a genus of the hexandria virginia class and order of plants. The calyx is three-leaved; corolla three-petalled; berry three-celled. There are three species, hardy perennials.

TRIM of a ship, her best posture, proportion of ballast, and lashing of her maist, &c., for sailing. To find the trim of a ship, to find the best way of making her sail well, or how she will sail best. This is done by easing of her masts and shrouds; one ship sailing much better when they are slack, than when they are taut or fast; but his depends much upon experience and judgment, and the several trials and observations which the commander and other officers may make aboard.

TRINGA, sandpiper, a genus of birds belonging to the order of gralica. The bill is somewhat tapering, and of the length of the head; the nostrils are small; the toes are in number and divided, the hind toe being frequently raised from the ground. According to Dr. Latham, there are 45 species, which 18 are British. We shall describe some of the more remarkable.

1. Vanellus, lapwing, or tewit, is distinguished by having the bill, crown of the head, crest, and throat, of a black colour; there is also a black line under each eye; the back is of a purplish green; the wings and tail are black and white, and the legs red; the weight is eight ounces, and the length 13 inches. It lays four eggs, making a slight nest with a few bents. The eggs have an olive cast, and are spotted with black. The young, as soon as hatched, run like chickens. He parents show remarkable solicitude for them, flying with great anxiety and clamber ear them, striking at either men or dogs that approach. They are still gathering along the round like a wounded bird, to a considerable distance from their nest, to delute their pears; and to aid the deceit, they become quite clamous when most remote from it.

The eggs are held in great esteem for their delicacy, and are sold by the London poulers for 4 or 5 shillings the dozen. In winter, spings joint in vast flocks; but at that season are very wild: their flesh is very good, their food being insects and worms. During October and November, they are taken in the fens in nets, in the same manner at ruffs are; but are not preserved for hunting, being killed as soon as caught.

2. Ploza. The male of this species is called ruff, and the female reeve. The name is given to the males because they are reared with very long feathers, standing it in a remarkable manner, not unlike the mill-worn by our ancestors. The ruff is of as many difference in size as there are marks in it; in general it is barred with black; the eight is six or seven ounces; the length one or.

The female, or reeve, has no ruff; the common colour is brown; the feathers are plumed with a very pale colour; the breast

TRI...
Trio, in music, a part of a concert wherein three persons sing; or more properly, a musical composition consisting of three parts. Trios are the finest means of composition, and these are what please most in concerts.

TRIOPETERIS, a genus of the decandria trigynia class of plants, the corolla whereof consists of three petaloid, epipetalous, equal and permanent petals, surrounded by three others, smaller than themselves, but equal to one another; there is no pericarpium; the seeds are three, erect, and carinated at the back, each of them has externally at its apex a wing, and at its apex two; these are what in the flowering state of the plant are called petals, but they are not truly such. There are two species, shrubs of the West Indies.

TRISTEOUM, a genus of the pentandria monogynia class and order of plants. The calyx is the length of the corolla; corolla one-petalled, almost equal; berry three-celled, unequal; seeds solitary. There are three species, herbs of North America. The roots are said to be medicinal.

TRIPLARIS, a genus of the diocca dodecandria class and order. The calyx is very large, three or six-parted; corolla three-petalled; nectar, three-sided. There are two species, trees of South America.

TRIPLE, or TRIPLE TIME, in music, a time consisting of three measures in a bar; the two first of which are beaten with the hand or foot down, and the third marked by its elevation. There were formerly in use no less than six different triple measures: first, that of three breves in a bar, denoted by the figure 3; secondly, that of three semibreves in a bar, the sign of which was \( \frac{3}{2} \); thirdly, that of three minims in a bar, marked by \( \frac{3}{4} \); fourthly, that of three crotchets in a bar, implied by \( \frac{3}{4} \); fifthly, that of three quavers in a bar, signified by \( \frac{3}{8} \); and, sixthly, that of three semiquavers in a bar, expressed by \( \frac{3}{16} \). But at present we employ only three different triples; that of three minims, that of three crotchets, and that of three quavers. The reader being informed that the semibreve is now, the longest note in common use, and therefore made the common standard of reckoning, is equal in duration to two minims; or to four crotchets, or eight quavers, will readily conclude the propriety of announcing these different measures by the above figures; and will perceive that, to indicate a time of three minims in a bar (i.e. three halves, or second parts, of a semibreve), no method more concise or simple could be adopted, than that of placing at the beginning of the movement the figures 3; for a time of three crotchets (i.e. three-fourths parts of a semibreve), the figures 4; and for a time of three quavers (i.e. three-eighths of a semibreve), the figures 8.

The old musicians considered the triple, or three-measure, time, as superior to the binary, or two-measure, and for that reason called it the perfect time.

TRIPLE PROGRESSION, an expression in old music, implying a series of perfect fifths. A progression of sounds thus explained by theorists; let any sound be represented by unity, or the number 1; and as the third part of a string has been to produce the twelfth, or octave of the fifth above the whole string, a series of fifths may be represented by a triple geometric progression of numbers, continually multiplied by 3; as 1, 3, 9, 27, 81, 243, 729; and these terms may be equally supposed to represent twelfths, or fifths, either ascending or descending; for whether we multiply or divide these florins by the terms will either be in the proportion of a twelfth, or octave to the fifth.

TRIPlicate ratio, the ratio which cubes bear to one another.

This ratio is to be distinguished from triple ratio, and may be thus conceived. In the geometrical proportions 2, 4, 8, 16, 32, as the ratio of the first term (2) is to the third (8) a duplicate of the first to the second, or of the second to the third, so the ratio of the first to the fourth is said to be triplicate of the ratio of the first to the second, or of that of the second to the third, or of that of the third to the fourth, as being compounded of three equal ratios. See Ratios.

TRIPOli, a mineral found sometimes in an earthy form, but more generally indurated. Its texture is earthy. Special gravity 2 to 2.5. It absorbs water, feels harsh and dry. Searce- taneous, and adheres to, or is detached from, the nodule; does not stain the fingers. Color generally pale yellowish gray; also different kinds of yellow, brown, and white. According to Klaproth, a species of this mineral contained

TRIPsACUM, a genus of the monoeica triandria class and order of plants. The male calyx its glume, four-flowered; corolla, glume membranaceous; female calyx, glume perforated sinuses; corolla, glume two-valved; styles two; seed one. There are two species, grasses of the West Indies.

TRISECTION, or TRISecTion, the dividing a thing into three. The term is chiefly used in geometry, for the division of an angle into three equal parts. The trisection of an angle geometrically, is one of those great problems whose solution has been so much sought by mathematicians for these two thousand years, being in the precise ratio to a given angle, and equal to the arc of the circle, and the duplication of the cube angle.

The cubic equation by which the problem is resolved, is as follows: Let \( x \) denote the chord of a given arc, or angle, and \( x \) the cord of the 5th part of the same, to the radius \( r \) then is \( x = \frac{5}{3} - x = -x \); and the resolution of the cubic equation in which the variable \( x \) is taken as the chord of the 5th part of the given arc or angle, whose chord is \( r \) and the resolution of this equation, by Cardan's rule, gives the chord

\[ x = \sqrt[3]{-\frac{1}{2} \pm \sqrt{\frac{1}{4} - \frac{5}{27}}} \]

TRISetoUs, in entomology, three-bristled, applied chiefly to the tail of insects as in the ephemera.

TRISPAST, in mechanics, a machine with three pulleys, or an assemblage of three pulleys for raising of great weights.

TRITICUM, wheat, a genus of plants of the class triandria, and order caryophyllaceae, and in the natural system ranging under the fourth order, gramina. The calyx is bivalve, solitary, and the fruit categorized as a dry fruit; the corolla is bivalve, one valve being bluish, the other acute. There are 19 species, the Aristum, summer or spring wheat; hybernum, winter, Lanneus, or common wheat, compositum, turgidum, or corn wheat; polo- nicus, or Polish wheat; spelta, or spelt wheat; monococum, or one-grained wheat, prostratum, or trailing wheat-grass; pumilum, or dwarf wheat-grass: juncus, or rush wheat-grass; repens, or couch-grass; tenuilus, or yellow wheat-grass; unialterale, or spiky wheat-grass; uniculme, or linear-spiked wheat-grass; dicthichium, loliaceum, cimicinum, hispanicum. Of what country the first six species are natives, cannot now be determined; the prostratum is a native of Siberia; the juncus, repens unialterale, and maritimum, are natives of Britain; the tenuilus is a native of Spain; and the unialterale is a native of Italy. It may also be observed, that the first three are annuals, the rest are perennials.

Linnaeus comprehends the different kinds of wheat cultivated at present under six species; but cultivation has produced a great many varieties from these.
1. Triticum aestivum, or spring-wheat, has four flowers in a calyx, three of which bear grain. The calyces stand very distantly from each other, on both sides of a flat smooth receptacle. The leaves of the calyx are keel-shaped, smooth, and they terminate with a short arist. The glumes of the flowers are smooth, the outer leaf of three of the glumes in every calyx is terminated by a short arist, but the three inner ones are beardless. The grain is rather longer and thinner than that of barley, but it is supposed to be of a native of some part of Tartary. The farmers call it spring-wheat, because it will come to the sickle with the common wheat, though it should be sown in February or March. The varieties of it are: Triticum aestivum, spica et grana rubente. Spring-wheat, with a red spike and grain. Triticum auratum rubrum, spica alba. Red spring-wheat, with a white spike. 2. Triticum hybrum, winter or common wheat, has also four flowers in a calyx, three of which are mostly productive. The calyces stand on each side a smooth arist and a small arist. The outer leaves of the glumes are smooth, and the outer leaves of the top of the spike, are often tipped with short arist. The grain is rather plumper than the former, and is the sort generally sown in England; whence the name of common wheat. Its varieties are: Triticum hybrum, spica et grana rubente. Common wheat, with a red spike and grain. Triticum hybrum rubrum, spica alba. Common red wheat, with a white spike. Triticum hybrum spica et grana alba. Common wheat, with a white spike and grain. Triticum vulgare, thick-skinned or common wheat. It is easily distinguished from either of the former species, as its calyx has four flowers in a calyx, after the manner of them, yet the whole calyx and the edges of the glumes are covered with soft hairs. The calyces too stand thicker on the receptacle, and make the grain of a larger size. Each of the outer glumes near the top of the spike are terminated by short arist, like those of the common wheat. The grain is shorter, plumper, and more convex on the back than either of the former species. Its varieties are numerous, and have various appellations in different counties, owing to the great affinity of several of them. Those most easily to be distinguished are: Triticum vulgare conicum album. Common wheat, with a white spike. Triticum vulgare conicum rubrum. Red common wheat. Triticum vulgare atrireum. Bearded common wheat. Triticum vulgare spica multiplici. Cone wheat, with many ears. The third variety is what the farmers call clog wheat, square wheat, and rivets. The grain of this is remarkably convex on one side, and when ripe the awn generally break in pieces and fall off. This sort is very productive, but it yields an inferior flour to that of the former two species. 4. Triticum Polonicum, or Polish wheat, has some resemblance to the turgidum, but both grain and spike are longer. The calyx contains only two flowers, and the glumes are furnished with very long arist; the teeth of both are bearded. As this sort is seldom sown, except by Englishmen, there is no telling what varieties it produces. 5. Triticum spelta, or German wheat. At first view this has a great resemblance to barley, but it has no involucrum. The calyx consists of three leaves as the ends of the awns were snipped off, and it contains four flowers, two of which are hermaphrodite, and the glumes bearded, but the intermediate ones are not. There are two rows of grain as in barley, but they are shaped like wheat. It is much cultivated in France, Germany, and Italy. 6. Triticum monococum, St. Peter's corn, or one-grained wheat, has three flowers in each calyx alternately bearded, and the middle one unerect. The spike is shining, and has two rows of grain in the manner of barley. Where it grows naturally is not known, but it is cultivated in Germany; and in common with wheat, is made into bread, which is coarse, and so nourishing as that made of common wheat. Malt made of any of our wheats is often put into beer, and a small quantity of it will give a large fermentation to that liquid in a very short time. Of the perennial kinds, or wild grasses, the repens, or couch grass is unfortunately too well known to the gardener and husbandman; the others are of little note. The respectable president of the Royal Society, whose attention is constantly directed to those branches of knowledge which are most practically useful, has published some remarks on the blight in corn in the year 1805, and we feel ourselves discharging a duty in making them as generally known as our circulation extends. He begins by observing that the blight in corn is occasioned by the growth of a minute parasitic fungus or mushroom on the leaves, stems, and grains of the living plant. Felice Fontana published, in the year 1767, an elaborate account of wheat, with microscopic figures, which give a tolerable idea of its form; more modern botanists have given figures both of corn and of grass affected by it, but hitherto not used high magnifying powers in such figures. He adds, "agriculturists do not appear to have paid, on this head, sufficient attention to the discoveries of their fellow-labourers in the field of nature; for though scarcely any English writer of note on the subject of rural economy, has failed to state his opinion of the origin of this evil, no one of them has yet attributed it to the real cause, unless Mr. Kirby's excellent papers on some diseases of corn, published in the Transactions of the Linnean Society, are considered as agricultural essays. It is, therefore, necessary to premise, that the striped appearance of the surface of a strand which may be seen with a common magnifying glass, is caused by alternate longitudinal partitions of the bark, the one imperforate, and the other furnished with one or two rows of pores or mothies, shut in dry, open in wet weather, and supplied with imbibable fluid whenever the strand is damp. By these pores, which exist also on the leaves and glumes, it is presumed that the seeds of the fungus gain admission, and at the bottom of the hollows to which they lead, (see Plate II. fig. 1, 2,) they permeate and push their minute roots, noddles (through these have not yet been traced) into the cellular texture beyond the bark, where they draw their nourishment, by intercepting the sap that was intended for the maintenance of the grain; the bark becomes shrivelled in proportion as the fungi are more or less numerous on the plant; and as the cortical part is abstracted from the grain, while the cortical part remains mutilated, the proportion of increase in in three days blighted corn, is always reduced in the same degree as the corn is made light. Some corn of this year's crop will not yield in stone of flour from a sack of wheat; and it is impossible that in some cases the corn has been so completely robbed of its flour by the fungus, that if the proprietor should choose to incur the expense of threshing and grinding it, bran would be the produce, with scarcely an atom of flour for each grain. Every species of corn, properly so called, is subject to the blight; but it is observable that spring corn is less damaged by it than winter, and rye less than wheat, probably because it is riped and cut down before the fungus has a chance to affect it. Full says that "white corn, or bearded wheat, which hath its straw like a rush full of pith, is less subject to blight than Lannus wheat, which ripens a week later." The spring wheat of Lincolnshire was not in the least shrivelled this year, though the straw was in some degree affected: the millers allowed that it was the best sample brought to market. Barley was in some cases very considerably injured, but as the whole of the stem of that grain is naturally enveloped in the bionse or basis of the leaf, the fungus can in no case gain admittance to the straw; it is, however, to be observed that barley ris from the field lighter this year than was expected from the appearance of the crop when gathered in. It seems probable that the leaf is first infected in the spring or early in the summer, before the corn shoots up into straw, and that the fungus then of its own accord spreads to the straw. When the straw has become yellow, the fungus assumes a deep chocolate brown: each individua is so small that every pore on a straw will produce from 20 to 40 fungi, as may be seen in the plates, and every one of these will not produce at least 100 seeds; if then one of these seeds falls out into the number of plants that appear at the bottom of a pore in Plate II. fig. 2, how incalculably large must the increase be! A few diseased plants scattered over a field must very speedily infect a whole neighbourhood, for the seeds of fungi are not much heavier than air, ani even when they lie on a ripe pull-ball must have been observed by some dozen among it is seed, rise up and float on him. How long it is before this fungus arrives at puberty, and scatters its seeds in the wind, can only be guessed at by the analogy of others; probably the period of a generation is short, possibly not more than a week in the hot season; so, how frequently in the 1st tier end of the summer must the air be loaded with this animated dust, ready, whenever a gentle breeze, accompanied with humidity, shall give the signal to intrude itself into the
pores of thousands of acres of corn. Providence, however, careful of the creatures it has created, has benevolently provided against the too extensive multiplication of any species of being; it was otherwise, the minute plants and animals, enemies against which man has the least defence, would increase to an inordinate extent; this, however, does not seem to be the case. Tell, in his Horseboarding Husbandry, page 74, tells us, that the year 1725 was a year of blight, the like of which was never before heard of, and which he hopes may never happen again; yet the average price of wheat in the year 1726, when the harvest of 1725 was market, was only 36s. 4d. and the average of the five years of which it makes the first, 3s. 7d. 1797 was also a year of great blight; the price of wheat in 1798 was 49s. 1d. and the average of the five years, from 1792 to 1799, 63s. 5d.

The climate of the British Isles is not the only one that is liable to the blight in corn. It happens occasionally in every part of Europe, and probably in all countries where corn is grown. Italy is very subject to it, and the last harvest of Sicily has been materially hurt by it. Specimens received from the colony of New South Wales, shew that considerable mischief was done to the wheat crop there in the year 1803, by a parasitical plant, very similar to the English one.

It has been long admitted by farmers, though scarcely credited by botanists, that wheat in the neighborhood of a barberry plantation escapes the blight. The village of Rollesby in Norfolk, where barberries abound, and wheat seldom succeeds, is called by the opprobrious appellation of niblew Rollo. The long memory of late has attributed this very perplexing effect to the fumigation of the flowers of the barberry, which is in truth yellow, and resembles in some degree the appearance of the leaves of the barberry, and is very subject to the attack of a yellow parasitical fungus, larger, but otherwise much resembling the rust in corn.

It is, however, notorious to all botanical observers, that the leaves of the barberry are very subject to the attack of a yellow parasitical fungus, larger, but otherwise much resembling the rust in corn.

Another year will not pass without its being confirmed by the observations of inquisitive and sagacious farmers.

It would be presumptuous to offer any remedy for a malady, the progress of which is so little understood; conjectures, however, founded on observation, would be designed to it, may be hazarded without offence.

It is believed to begin early in the spring, and first to appear on the leaves of wheat in the form of rust, or orange-coloured powder; at this season, the fungus will, in all probability, require as many weeks for its progress from infancy to puberty, as it does days during the heats of autumn; but a very few plants of wheat, thus infected, are quite sufficient if the fungus is permitted to ripen its seed, to spread the malady over a field, or indeed over a whole parish.

The chocolate-coloured blight is little observed till the corn is approaching very nearly to ripeness; it appears then in the field in spots, which increase very rapidly in size, and are in calm weather somewhat circular, as if the disease took its origin from a central position.

May it not happen, then, that the fungus is brought into the field in a few stalks of infected straw, uncorrupted, among the mass of dung laid in the ground at the time of sowing? It must be confessed, however, that the idea of wheat having being found in the yard where the corn was used, were as much infected last autumn as the manured crops. The immense multiplication of the disease in the last season, seems, however, to account for this; as the supply of straw was such that they were not equal for seed for miles together, and deposited it indiscriminately on all sorts of crops.

It cannot, however, be an expensive precaution to search diligently in the spring for young plants of wheat infected with the disease, and carefully to extirpate them, as well as all grasses, for several are subject to this or a similar malady, which have the appearance of orange-coloured or of black stripes on their leaves, or on their straw; and if experience shall prove that uncorrupted straw can carry the disease with it into the field, it will cost the farmer but little precaution to prevent any mixture of fresh straw from being carried out with its rotten dung to the wheat field.

In a year like the present, that offers so fair an opportunity, it will be useful to observe attentively whether cattle in the straw-yard thrive better or worse on blighted than on healthy straw. That blighted straw, retaining on it the fungi that have robbed the corn of its flour, has in it more nutritious matter than clean straw which has yielded a crop of plump grain, without doubt; the question is, whether this nutriment in the form of fungi does, or can be made to agree as well with the stomachs of the animals that consume it, as it would do in that of straw and corn.

It cannot be improper in this place to remark, that although the seeds of wheat are rendered, by the exhausting power of the fungus, so lean and shrivelled, that scarcely any flour can be obtained from them, these very seeds will, except, perhaps, in the very worst cases, answer the purpose of seed-corn as well as the fairest and plumpest sample that can be obtained, and, in some respects, better; for as a bushel of much blighted corn will contain one-third, at least, more grains in number than a bushel of plain corn, three bushels of such corn will go as far in sowing land, as four bushels of large grain.

The use of the flour of corn in furthering the process of vegetation, is to nourish the minute plant from the time of its development, its roots in some measure extracting food from the manured earth; for this purpose, one-tenth of the contents of a grain of good wheat is more than sufficient. The quantity of flour in which has been increased by cultured management, to improve its qualities for the benefit of mankind, in the same proportion as the pulp of apples and pears has been increased, by the same means, above what is found on the wildings and crabs in the hedgerow.

It is customary to set aside or to purchase for seed-corn, the boldest and plumpest samples that can be obtained; that is, those that contain the most flour; but this is an unnecessary waste of human subsistence; the smallest grains, such as are sitted out before the wheat is carried to market, or rather consumed in the farmer's family, or given to his poultry, will be found by experience to answer the purpose of propagating the sort whence they sprung, as effectually as the largest.

Every part of a ear is composed of a number of cups placed alternately on each side of the straw; the lower ones contain, according to circumstances, three or four grains, nearly equal in size, but towards the top of the ear, where the quantity of nutriment is diminished by the supply of cups that are nearer the root, the third or fourth grain in a cup is frequently defaumed of its proportion, and becomes shrivelled and small. These small grains, which are rejected by the miller, because they do not contain flour enough for his purpose, have, nevertheless, an ample abundance for all purposes of vegetation, and as fully pactate of the cap, (or blood, as we should call it in animals,) of the kind which produced them, as the fairest and fullest grain that can be obtained from the bottoms of the lower cups by the wasteful process of beating the sheaves.

TRITOMA, a genus of insects of the coleoptera order. The generic character is, elavate, scrobilate; by emarginate; anterior feelers hatchet-shaped; shells as long as the body. There are ten species.

TRITON, a genus of vermcs molusca. The generic character is, body long; month with an involute spiral proboscis; tentacles or arms, twelve, viz. six on each side, divided nearly to the base, the end ones cheliferous. There is only a single species, viz. the litteorous, which is found in Italy, in various cavities of submarine rocks, and may be seen in many species of the lepas, particularly in the anatara.

TRIURATIOn. See Pharmacy.

TRIUMFETTA, a genus of the dodacan- dria monogynia class of plants, the corolla of which consists of five linear, crete, obtuse petals, hollowed, and bent backwards; the point is prominent below the apex; the fruit is a globus capsule, every where surrounded with longed prickles, and contains four cells; the seeds are two, convex on one side and angular on the other; but only one of the two
seeds of each cell usually ripen. There are 11 species, chiefly shrubs of the West Indies.

TRIXIS, a genus of the synsegea polyantha of order of plants. The corolla of the ray are triate, seeds hairy at the top, without any down; recept. chaffy. There are three species, herbs of the West Indies.

TROCHIAL VERSE, in the Latin poetry, a kind of verse, so called because the trochee of the foot prevails as the iambus does in the iambic. It generally consists of seven feet and a syllable; the odd feet, for the most part, consist of trochees, though a tribrachys is sometimes admitted, except in the seventh foot; but all are remarkable for the beauty of the latter part, as is also the spondaic, dactylus, and anaestus. The following is an example:

1. Solus aut rex aut po et non quot
   annis aut usque aut tor.

TROCHANTER, See Anatomy.

TROCHE, See Pharmacy.

TROCHEE; in the Greek and Latin poetry, a foot consisting of two syllables, the first long and the second short, as in the words massa and servat.

TROCHILUS, humming-bird, a genus of birds belonging to the order of picce. The rostrum is subulate, niform, and longer than the head, the apex being tubular; the upper mandible slightly the lower. The tongue is filiform and tubulous, the two threads coalescing; the feet are slender and fit for walking; the tail has ten feathers. There are 65 species, none of which are natives of Britain. They are all remarkable for the beauty of their colours, and most of them for the smallness of their size, though some are eight or nine inches in length. They are divided into two families, viz. those with crooked bills, and those with straight bills. See Plate Nat. Hist, fig. 408. Of these we shall describe the four following species:

1. The exilis, or little humming-bird, has a crooked bill, is an inch and a half in length; the upper mandible is lighter; the tongue is black, and half an inch in length; the body greenish-brown, with a red shining, immittible gloss; the head is crested with a small tuft, green at bottom, but of a sparkling yellow colour at top; quills and tail fine black. It is a native of Guiana; and the oscillation of its body is so great, that the eye can scarcely keep pace with its motion.

2. The mollichus, or ruby-necked humming-bird, according to Mixagrace, is the most beautiful of the whole genus. Its length is three inches four lines; the bill straight, eight lines long, and blackish; the top of the head and hind part of the neck are as bright as a ruby, and of the same colour; the upper parts of the body are brown, with a faint mixture of green and gold; the throat and forepart of the neck are the colour of the most brilliant topaz; the belly, sides, and thighs, are brown; but on the under part of the belly, on each side, is a spot of white; the tail is russet purple, inclining to violet at the ends; the two middle feathers are shortest; the legs and claws blackish. The female has the head golden or topaz on the breast and forepart of the neck; the rest of the under parts are greyish-white. This species is found in Brasil, Curassow, Guiana, and Surinam. See Plate Nat. Hist. fig. 4-9.

3. The minimum, or least humming-bird, is exceeded, both in weight and dimensions, by the T. exilis; its total length is one inch and a quarter; and when killed, weighs no more, according to Sir Hans Sloane, than 20 grains. The bill is straight and black, three lines and a half in length; the upper parts of the head and body, are of a greenish-golden brown, in some lights appearing reddish; the under parts are greyish-white; the wings are violet-brown; the tail of a bluish-black, with a gloss of polished metal; but the outer feather, except one on each side, is grey from the middle to the tip, and the outer one wholly grey; legs and claws brown. The female is less than the male; the whole upper side of a dirty brown, with a slight gloss of green; the under parts of a dirty-white. These birds are found in various parts of South America and the adjacent islands.

4. Superbissimus, white shaft, or superbus-humming-bird, is a very beautiful species. Its wings are very long; the feathers of the tail next the two long shafts are also the longest, and the lateral ones continually decrease to the two outermost, which are the shortest, and this gives the tail a pyramid shape; its quills have a gold gloss on a grey and blackish ground, with a whitish edge at the point, and the two shafts are white through the whole projecting portions; all the upper side of the back and head, and yellow gold-colour; the wing violet-brown; and the under side of the body white-grey.

These birds subsist on the nectar or sweet juice of flowers; they frequent those most which have a long tube, particularly the impatiens noli me tangere, the monarda with crimson flowers, and those of the convolvulus tribe. They never settle on the flower during the action of extracting the juice, but flutter continually like bees, moving their wings very quick, and making a humming noise; whence their name. They are not very shy, suffering people to come within a foot or two of the place where they are, but when approached nearer, fly off like an arrow out of a bow. They are well provided with the right for a flower, and this all on the wing. In this state they often come into rooms where the windows stand open, fight a little, and go out again. When they come to a flower which is juiceless, or on the point of withering, they pluck it off as if in anger, by which means the ground is often quite covered with them. When they fly against each other, they have, besides the humming, a sort of chirping noise like a sparrow or chicken. They do not feed on insects or fruit; nor can they be kept long in cages, though they have been preserved alive for several weeks together, by feeding them with water in which sugar had been dissolved.

This bird most frequently builds in the middle of a branch of a tree, and the nest is so small that it cannot be seen by a person who stands on the ground; any one therefore who wishes to see the lower side, go up to the branch, that he may view it from above: it is for this reason that the nests are not more frequently found. The nest is of course very small, and quite round; the outside, for the most part, seems to be common, composed of two main parts, covered on old pales and trees; the inside of soft down, mostly collected from the leaves of the great mullein, or the silk grass; but sometimes they vary the texture, making use of flax, hemp, hair, and other soft materials; they lay two eggs of the size of a pea, which are white, and not bigger at one end than the other.

The above account of the manners will in general suit all the birds of this genus; for as we have already seen, in their first acquisition, it is by this method alone that they can gain nourishment: no wonder, therefore, they can scarcely be kept alive by human art. Captain Davies, however, kept these birds alive for four months by the following method: He made an exact imitation of the edge of the tubular flowers with paper, fastened round a tobacco-pipe, and painted them of a proper colour; these were placed in the order of nature, in the cage wherein these little creatures were confined, and in the bottoms of the tubes were filled with a mixture of brown sugar and water as often as emptied; and he had the pleasure of seeing them perform every action as if for the first time; for they soon grew familiar, and took the nourishment in the same manner, and ranging at large, though close under his eye.

TROCHOID. See Cycloid.

TROCHUS, a genus of vermes testaceae: the generic character is, animal a linnæus; shell univalve, spiral, more or less conic; aperture somewhat angular or rounded; the upper side transverse and contracted; pillar placed obliquely. See Plate Nat. Hist, fig. 410. There are about 120 species.

TROGON, or cernuus, a genus of birds of the order picae. The generic character is, bill shorter than the head, sharp-edged, hooked, the mandibles separated; none of them having feathers for climbing. There are nine species. They all inhabit warm countries, are solitary, and live in damp unfrequented woods, building on the lower branches; their sight is short, and they feed on insects; body long; nostrils covered with bristles; feet short, woolly; tail very long, consisting of 12 feathers.

TROLLIUS, globeflower, in botany, a genus of plants of the class polyandria, and order polygama, found in the natural system ranging under the 26th order, multisilique. The calyx is wanting; there are about 14 petals; the capsules are very numerous, ovate, and many seeded. There are two species, the asiaticus and europaeus; the latter of which is a British plant. The europaeus, or European globeflower, has its corypate convolvous, and from nine to sixteen nectarins, of the length of the staminal, linear, plane, incurvate, and stellariated at the upper side of the base. The leaves are divided first into five segments down to the base; the segments are again divided, each about half-way, into two or three lobes, which are sharply indented on the edge. In the stalk is a foot high, and scarcely branched; the flower is yellow, globose, and sparcacious. It grows at the foot of mountains, and by the sides of rivulets. The country people in Sweden strew their floors and pavements on holidays with the flowers, which have a pleasant smell, and are ornamental in gardens. The asiaticus is little different, except that the corolla inclines to orange.

TROUPE, the mayor and commonalty of the city of London, are ordained keepers
of the beams and weights for weighing merchants' commodities, with power to assign clerks, porters, &c., of the great beam and the weights of goods and wares, is called tonnage.

TROPIC, EQUATOR. The Indian cress, or Anarthrostis, a genus of the octandria-monogyne class of plants, the flower of which consists of five roundish petals inserted into the divisions of the cypsel, the two upper petals are sessile; the three others have very long and barbated anthers; the fruit consists of three convex capsules, fulculated, and striated on one side, and angular on the other; the seeds are thin, glossy, and marked. This is usually detains.

TROPHY, a name given to the top of the mast, containing the four-petalled compass; the style is two-parted; bery one-seeded. There is one species, the random tree of Jamaica.

TROPHY, sporangium, among the amanites, a pile or heap of arms of a vanquished enemy, raised on the mountain and parts of the field of battle. The trophies were usually dedicated to some of the gods, especially Jupiter. The name of the deity to whom they were inscribed, was generally mentioned, either in the mountain or parts of the field of battle. The gods were at first hung upon the trunk of a tree; but instead of trees, succeeding ages erected pillars of stone, or brass, to continue the memory of their victories. To demolish a trophy was looked upon as a kind of sacrilege, because they were all consecrated to some deity. The representation of a trophy is often to be met with on medals of the Roman emperors, struck on occasion of victories; when relays, besides arms and spoils, are frequently seen one or two captives by the sides of the trophy.

TROPIES. See ASTRONOMY, and Geography.

TROUGHER. The trough is the remedy prescribed by the law, where any person is in possession of the property of another, which he unlawfully detains. Previous to commencing of this action, a demand of the property so detained is to be made in writing by some person properly authorized by the owner of the property; and upon refusal to restore it, the law presumes an unlawful conversion, and the party is entitled to this action, and will recover damages to the value of the property detained. As trough implies trespass, the smallest damages will carry costs. A similar action may be brought for the unlawful detention of any property, on which the specific article so detained may be recovered; but as articles detained must be precisely stated in the declaration, and is attended with some difficulty, this action is very seldom brought.

TROUT. See SMALO.

TROUT-WEIGHT. One of the most ancient and different kinds used in Britain. The ounce of this weight was brought from Grand Cairo in Egypt, about the time of the crusades, into Europe, and first adopted in Troyes, a city of Champagne, whence the name of Troy weight and Troy ounce contains 17 ounces, or 5760 grains. It was formerly used for every purpose; and is still retained for weighing gold, silver, and jewels; in some degree for compounding medicines; for experiments in natural philosophy; and for comparing different weights with each other. It is reckoned to be equal to nearly the weight of 22 pounds, 11 ounces, and 3 pennyweights. 

James I. in the year 1618, who enacted, that only one weight should be used in Scotland, viz. the French Troy stone of 16 pounds, and 16 ounces in the pound. The pound contains 7620 grains, and is equal to 17 or 6 dr. avoirdupois. The ext. or 112 lb. avoirdupois, contains only 103 lb. 25 oz. of this weight, though generally reckoned equal to 104 lb. This weight is nearly, if not exactly, the same as that of Paris and Antwerp, and is generally known by the name of Dutch weight. Though prohibited by the articles of union, it is still used in weighing iron, hemp, flax, most Dutch and Baltic goods, wool, brush-mat, furrowed pewter and lead, and some other articles. See WEIGHTS.

TRUCE, in war, denotes a suspension of arms, or a cessation of hostilities between two armies, in a form of articles of peace, bury the dead, or the like.

TRUFFLES, in natural history, a kind of subterranean puff-ball, being a species of fungi, which grows under the surface of the earth in woods.

TRUMPET, the loudest of all portable wind instruments, and consisting of a folded tube generally made of brass, and sometimes of silver.

The inventors had various instruments of the trumpet kind, as the tuba, cornua, &c., as the scripture informs us, made two of silver to be used by the priests; and Solomon, Josephus tells us, made two hundred like those of Moses, and for the same purpose.

The modern trumpet consists of a mouth-piece, near an inch across. The pieces which conduct the wind are called the branches; the parts in which it is bent the potencies; and the canal between the second bend and the extremity the pavilion; the rings where the branches take asunder, or are soldered together, the knots, which are five in number, and serve to cover the joints.

One particular trumpet, the Porta, or noble instrument, is that, like the horn, it only commands certain notes within its compass.

The trumpet produces, as natural and easy sounds, G above the bass-cliff note, or fiddle G, C on the first ledger line below in the treble, E on the first line of the stave, G on the second line, C on the third space, and all the succeeding notes up to G in alt, including the sharp of B, the fourth of the key.

Solo performers can also produce B flat (the third above the treble-cliff note) and by the aid of a newly invented slide many other notes which the common trumpet cannot sound are now produced. A method has lately been discovered for enriching the inside of trumpets, so as not to injure the fineness of the sound, and yet to prevent the deleterious effects occasioned by drawing in the oxide of copper into the lungs.

TRUMPET marine, a kind of monochord, forming the name and shape of a triangle, triangular body. It has a very narrow neck, with one thick string, mounted on a bridge, which is firm on one side, and tremulous on the other. It is struck with a bow by the right hand, and the thumb of the left hand is depressed on the string. The peculiarity of its sound, which resembles that of the trumpet, is produced by the tremulation of the bridge.

TRUMPET, harmonical, an instrument that imitates the sound of a trumpet, which it resembles in every thing, excepting that it is longer, and consists of more branches; it is also called a portable trumpet.

TRUMPET, speaking, is a tube from six to fifteen feet long, made of tin, perfectly straight, and with a very large aperture; the mouth-piece being large enough to receive the lips.

The speaking-trumpet, or stentorophonic tube, as some call it, is used for magnifying sound, particularly that of speech, and thus causing it to be heard at a greater distance. How it does this will be easy to understand from the structure of it, thus illustrated: Let ACB be the tube, the axis, and B the mouth-piece for conveying the voice to the tube. Plate Miscel. fig. 244.

It is then evident, when a person speaks at B, the trumpet, the whole force of his voice is spent upon the air contained in the cylinder ABCD, so as to move it through the whole length of the tube; and by various reflections from the side of the tube; to the axis, the air along the middle part of the tube will be greatly condensed, and its momentum proportionally increased, so that when it comes to agitate the air at the orifice of the tube AC, its force will be much greater than what it would have been without the tube, as the surface of a sphere, whose radius is the orifice of the tube, is greater than the surface of the segment of such a sphere, whose base is the orifice of the tube.

See SOUND.

For a person speaking at B, without the tube, will have the force of his voice spent in exciting concentric superifices of air all around the point B; and when those superifices or pulses of air are diffused as far as D every way, it is plain the force of the voice will be diffused through the whole superifices of air everywhere. But in the trumpet it will be so confined, that at its exit it will be only diffused through so much of that spherical surface of air, as corresponds to the orifice of the tube. But since the force is given, its intensity will be always inversely, as the number of particles it has to move; and therefore in the tube it will be that without, as the superificies of such a sphere to the area of the large end of the tube.

To make this matter yet plainer by calculation, let BD = 5 feet, then will the diameter of the sphere DE = 10 feet, the square of which is 100, which, multiplied by 0.7854, gives 78.54 square feet for the area of a great circle. And, therefore, four times that area, viz. 4 x 78.54 = 314.16 square feet in the superifices of the aerial sphere. If now the diameter AC, of the end of a trumpet, is one foot, its area will be 0.7854; but 7834 = 314.16, which is the diameter BD; and the former trumpet at the distance of BD, will be agitated by the air of the trumpet, with a force 400 times greater than by the bare voice alone. Again, it is further evident how instruments of this form necessarily for the waking and guiding pulses of the air being received by the
large end of the tube, and greatly multiplied
and condensed by the tremendous motion of
the parts of air which are agitated by
those of another. These are conveyed to
the small end, and strike with an impetus so much
larger than they would have done without it,
that the area of the small end is about 9
less than the area of the larger end AC. From
what has been said, it is evident the effect of
the tube in magnifying sound, either for
speaking or hearing, depends chiefly upon
the length of the tube. But yet some advan-
tage may be derived from the particular
shape. Some have proposed the figure which is made by
the revolution of a parabola about its axis, as
the best of any, where the mouth-piece of the
parabola, and, consequently, the sonorous
rays will be reflected parallel to the axis of
the tube. But this parallel reflection seems
no way essential to the magnifying of sound;
therefore, it appears rather to hinder
such an effect, by preventing the infinite
number of reflected circular reciprocations
of sound; in which, according to sir ISAAC
Newton, its augmentation principally consists.
For all reciprocal motion, in every return,
is augmented by its generating cause, which is
then the transmission of the wave to the tube.
In every repercussion, therefore,
from the sides of the tube, the agitations
and pulses of confined air must necessarily be in-
creased; and consequently this augmentation
of the impetus as the waves must be propor-
tional to the number of such repercussions;
and therefore, to the length of the tube, and
to such a figure as most productive of them.
Whence it appears that the parabolic trumpet
is not all the most useful for this purpose, in-
stead of being the best.

But there is one thing more which contrib-
utes to the augmenting of these agitations
of air in the tube, and that is the proportion
which the several portions of air bear to each
other, when divided by transverse sections,
at very small, but equal distances, from
one end of the tube to the other. Thus,
let those several divisions be made at the points
or stations, a, b, c, d, &c. be taken in geometrical
proportion. Then will the portions of air con-
tained between Band c, a and b and c, cc
and d, &c. be very nearly in the same propor-
tion, as being in the same ratio with their
bases, when the points of division are inde-
minitely near together.

But when any quantity of motion is com-
municated to a series of elastic bodies, it will
receive the greatest augmentation when those
bodies are in geometrical proportion. There-
fore, since the force of the voice is impressed
upon, and gradually propagated through,
a series of elastic portions of air in a geo-
metrical ratio to each other, it shall receive the
greatest augmentation possible.

Now, since by construction it is B = be =
bc = cd, &c. and also aO = ab = bO = cO;
dc, and so on; therefore, the points k, m,
n, a, p, k, r, s, as will, in this case, form
that curve line called the logarithmic curve;
consequently a trumpet, formed by
the revolution of this curve about its axis,
will augment the sound in a greater degree
than any other figured tube whatever.

TRUMPET—FLOWER. See Bignonia.
TRUMPET-SHELL, the English name of
the buccinum of authors. See Buccinum.

TRUNCATED, in general, is an
appellation given to such things as, have
or seem to have, their points cut off: thus we say, a
truncated cone, pyramid, leaf, 

TRUNCNIONS, or TRUNIONS of a piece
of ordnance, are those knobs or
hinges of the gun's metal, which bear up on the
choke of the cannon: and hence the term
ring is the ring about a cannon, next
before the trunnions.

TRUSSES, in a ship, are ropes made fast
to the parcels of a yard, either to bind the yard
to the mast when the ship rolls, or to hold
unto the yards in a storm, &c.

TRUSTEE, one who has an estate, or
money, put or trusted in his hands, for
the use or benefit of another. More
person or persons are appointed trustees, if one of them
receives all or the greater part of the profits
of the lands, &c. and is in a strict sense, and unable to
satisfy the person to whom he is seised in trust, the other, in that case, shall not be
answerable for any thing more than comes to his hands.

TUBE, in general, pipe, conduit, or canal;
a cylinder, hollow withinside, either of lead,
iron, wood, glass, or other matter, for
the air, or some other fluid, to have a free passage
or conveyance through.

Small size or lemon tubes are frequently
used by surgeons to draw off blood, matter,
or water, from the different parts of the body.
They are made of various sizes and shapes.

TUBE, in astronomy, is sometimes used
for a telescope, or, more properly, for that
part into which the lenses are fitted, and by which
they are directed and used. See OPTICS.

TUBIPORA, a genus of zoozoa. The
generic character is, animal a ureas; coral
consisting of erect, hollow, cylindrical, parallel
gap aggregate tubes. There are ten species:
The most eminent inhabits the Indian seas, is fixed to rocks and other corals; builds
scarlet, consisting of an assortment of upright
parallel tubes, rising over each other by
stages, like cells of an honeycomb, divided
by transverse partitions. The Indians use it
in cases of strangury, and wounds inflicted by
venomous animals.

TUBULARIA, a genus of zoozoa. Stem
tubular, simple or branched, fixed by the
base: animal proceeding from the end of the
smaller tubes, and having its head erected with tenta-
cula. There are 20 species: the magnifica
inhabits the West Indies, adhering to rocks,
and is the most splendid genus of them all:
it has the power of withdrawing its tentacula
within the tube, and the tube within the rock
on which it resides.

TUFAS, beds of limestone deposited on
vegetables, which by their destruction give
lightness and porosity to the mass.

TURK, a term for tail; a sort of standard, called so by the
Turks. It consists of a horse's tail, which
is fixed to a long pole or half-pike, by means
of a gold button. The origin of this standard is
curious. It is said, that a new name given to
the Turks, the latter were
broken, and in the midst of their confusion
lost their grand standard. The Turkish
general, being extremely aggrieved at the untoward
conditions which happened, most
especially by the loss of the great standard,
cut off a horse's tail with his sabre, fixed it to
a half-pike, and holding it in his hand, rode
furiously towards the fugitives, and exclaimed,
'Here is the great standard; let those who
love me, follow into action.' This
produced the desired effect. The Turks rallied
with redoubled courage, rushed into the
thickest of the enemy, and not only gained
the victory, but recovered their standard.

TURPENTINE, a spirit which is
obtained from the resinous substance
being distilled from the bark of a
particular sort of fir tree, and is,
when perfectly purified, a clear
liquid. It is employed in medicine
and chemistry, and is very
valuable.

TUSK, a name given to the bone, or
hard, thick white piece, which is
attached to the upper and lower jaws
of the elephant. Some species of
elephant have only one tusk,
whereas others have two.
man Army; they still made use of the flag or turban; and the Turks, in consequence of the victory which was obtained under this mark standard, looked upon it as a happy omen; and that since that period they have always fought under it as their banner, and the signal of victory.

Whatever may have been the origin, it is certain, that when the grand signor takes the field in person, seven of these tails are always carried before him; and when he is in camp, they are placed in front of his tent.

The grand visier is entitled to three of these tails.

The three principal basinews of the empire, viz. those of Bagdad, Grand Cairo, and Breda, have the grand signor's permission to use this mark of distinction, throughout the whole extent of their jurisdiction.

Those basinews that are not visiers have the privilege of having two tails.

The boys, who are subordinate to the basinews, have only one.

TULIPAGE, a genus of plants of the class and order hemixidia monogynia. The corolla is fumose-nod; nect. three-leaved; capsule saccate. There are two species, bulbs of the Cape.

TULIP. See TULIPA.

TULIPA, tulip, a genus of plants of the class hemixidia, and order monogynia, and in the natural system, or common garden tulip, is the commonest, or most popular, of the whole tulip genus, a native of the Levant; the breynianus, or cape tulip, a native of the Cape of Good Hope, the bilora, and the stovaleous.

1. The sylvestris, or wild European tulip, has an oblong bulbous root, sending up long narrow spear-shaped leaves; and a slender stalk, supporting at top a small yellow flower, making on this side, having acute petals.

2. The generica, Gener's Turky tulip of Constantinople garden tulip, has a large, oblong, tumicate, solid, bulbous root, covered with a brown skin, sending up long, oval, spear-shaped leaves; an upright round stalk, from half a foot to a yard high, and bearing a large bell-shaped erect hexapetalous flower, of almost all colours and varieties in the different varieties.

This tulip, and its vast train of varieties, is generally cultivated for the ornament of our gardens, and much admired by all for its great variety and beautiful appearance; it grows freely in the open ground in any common soil of a garden, and proves a very great decoration to the beds and borders of the pleasure-ground for six weeks or two months in spring, by different plantings of early and late sorts; planting the principal part in autumn, and the rest towards Christmas, and in January or February. The autumn plantings will come earliest into bloom, and flower the strongest; and the others will succeed them in flowering. In summer, when the flowering is past, and the leaves and stalks assume the attitude of the chions in all the varieties are generally taken up, the offsets separated, and the whole cleaned from filth; then put up dry till October or November, and planted again for the future year's bloom.

Of this species, which is the florist's delight, the varieties may be divided into two principal early or old; and spring tulips (practicals). 2. Late flowering common tulips (scentuine). 1. Early tulips. The early tulips are, among florists, distinguished by the application of precoces, (early) because they flower early in the spring, a month or more before the others; they are much taller, and the flowers smaller, but in great reputation for their early bloom and their gay lively colours, both of self-colours, and broken into combinations, such as reds, crimson, scarlet, cinnamons, violets, purples, yellow, &c. with flowers of each, edged and flaked with red, yellow, and white, in many diversities. 2. Late flowering common tulips. This class is denominated late flowering, and by the florists called serotine, because they blow later in the spring, a month or more, than the precoces, i.e. not coming into flower before the end of April, May, and June. These are all of tall growth, supporting large flowers, and furnish an almost endless variety in the vast diversity of colours; after, they break from whole flowers into variegations and stripes, exceeding all others of the tulip kind in beauty and elegance of flower.

All the varieties are succeeded by plenty of ripe seed in July and August, contained in an oblong capsule of three cells, having the seeds placed on each other in double rows. By the seeds many new varieties may be raised, which however will not attain a flowering state till they are seven or eight years old; and after that will require two or three years, or more, to break into variegations, when the approved varieties may be marked, and increased by offsets of the root.

The colours in greatest estimation in variegated tulips are the blacks, golden yellows, purple-violets, rose, and vermillion, each of which being variegated various ways; and such as are striped with three different colours distinct and unmixed, with strong regular streaks, but with little or no tinge of the breeder, may be called the most perfect tulips. It is rare to meet with a tulip possessing all the above properties.

As to the colouring of obtaining this wonderful variety of colours in tulips, it is often accomplished by nature alone, but is sometimes assisted and forwarded by some simple operations of art; such as that, in the first place, when the seedling bulbs of the whole flower or breeder are arrived to full size, and have flowered once, to transplant them into beds of any poor dry barren soil, in order that, by a defect of nourishment in the earth, the natural luxuriance of the plant may be checked, and cause a weakness in their general growth, whereby they generally, in this weakened or infirm state, gradually change and break out into variegations, some of the first year, others not till the second or third; and according as they are thus broken they should be planted in beds of good earth.

Another method to assist nature in effecting the breaking the breeding tulips into diversified colours, is to make as great a change as possible in the soil; if they were this year in a light poor soil, and next year in rich garden mould, and another year in a compost of different earths and dung; or transplant them from one part of the garden to another, or into different gar lands, &c. or from one country to another; all of which contributes to assist nature in producing this desirable diversity of colours and varieties.

The double tulip is also a variety of the common tulip, and is very beautiful, though not in such estimation among the florists as the common single variegated sorts, not possessing such a profusion of variegations in the colours and regularity of stripes; they however exhibit an elegantly ornamental appearance.

Tulip roots are sold in full collection, consisting of numerous varieties, at most of the nurseries and seedsmen, who both propagate them themselves by offsets and seed, and import vast quantities annually from Holland, the Dutch being famous for raising the greatest collections of the finest tulips, and other bulbous flowers, in the greatest perfection. TUMOUR, or Tumor, in medicine and surgery, a preternatural rising or hard swelling on any part of the body.

TUN, or Tun, signifying a large vessel or cask of an oblong form, biggest in the middle, and diminishing towards its two ends, girt about with hoops, and used for containing several kinds of merchandise, for convenience of carriage, as wine, oil, &c.

TUN is also a certain measure for liquids; as wine, oil, &c. See Tun and Sound.

Tun, or Tone, in music, that property of sounds whereby they come under the relation of acute and grave to one another. See Tun and Sound.

Sonorous bodies we find differ in tone: 1. According to the different kinds of matter; thus a wedge of silver sounds much more acute than a wedge of gold of the same shape and dimensions, in which case the tones are proportional to the specific gravity. 2. According to the different quantities of the same matter in body, as when, by striking a solid sphere of brass, one foot diameter, sounds acuter than one of two feet diameter; in which case the tones are proportional to the quantity of matter. Here then are different tones connected with different specific gravities and quantities of matter, as their immediate cause. In effect, the measures of tune are only sought in the relations of the motions that are the cause of sound, which are no way so discernible as in vibrations of chords.

In the general we find that in two chords, all things being equal, except tension, or thickness, or length, the tones are different; there must, therefore, be a difference in the vibrations owing to these different tensions, &c., which difference can only be in the velocity of the courses and recourses of the chords, through the spaces wherein they are produced and sprung. Upon examining the proportion of the velocities of the things just mentioned, wherein it depends, it is found, to a demonstration, that all the vibrations of the same chord are performed in equal times. Hence, all one of a sound depends on the nature of the vibrations, whose difference we can conceive no other.
Thus, for but the it and it and a quantity of charcoal, and heated the mixture in a crucible. The result of their experiments is as follows:

With gold and platinum the tungsten did not combine.

With silver it formed a button of a whitish-brown colour, something spongy, which with a few strokes of a hammer extended itself easily, but on continuing it split in pieces. This button weighed 142 grains.

With copper it gave a button of a copperish red, which approached to a dark brown, was spongy, and very ductile, and weighed 133 grains. With crude or cast iron, of a white quality, it gave a perfect button, the fracture of which resembled that of a whitish brown colour; it was hard, harsh, and weighed 137 grains; and with lead it formed a button of a dull dark brown, with very little lustre, spongy, very ductile, and splitting into leaves when hammered: it weighed 127 grains.

The button formed with tin was of a lighter brown than the last, very spongy, somewhat ductile, and weighed 138 grains.

That with antimony was of a dark-brown colour, shining, something spongy, harsh, and broke in pieces easily: it weighed 108 grains.

That of bismuth presented a fracture, which, when seen in one light, was of a dark brown colour, with the lustre of a metal, and in another appeared like earth, without any lustre; but in both cases an infinity of little holes could be distinguished over the whole mass. This button was pretty hard, harsh, and weighed 68 grains.

With manganesine it gave a button of a dark-bluish-brown colour and earthy aspect; and on examining the internal part of it with a lens, it revealed an impure dress of iron; it weighed 107 grains.

TUNGSTIC ACID. The substance called tungstic acid by Scheele and Bergman was discovered by Scheele in 1781. This philosopher obtained it from the tungstate of lime, by treating it with nitric acid and ammonia alternately. The acid dissolves the lime, and the ammonia combines with the tungstic acid. The ammoniacal solution, when saturated with nitric or muriatic acid, deposits a white powder, which is the tungstic acid of Scheele.

This powder has an acid taste, it reddens vegetable blues, and is soluble in 20 parts of boiling water. The De La Vayres have demonstrated, that this pretended acid is a compound of yellow oxide of tungsten, the alkali employed to dissolve it, and the acid used to precipitate it. Thus, when prepared according to the above-described process, it dissolves the carbonates, nitrates, and nitric acid. Their conclusions have been more lately confirmed by the experiments of Vauquelin and Hechel.

This substance must therefore be erased from the class of acids, and placed among the salts. 2 N.

The real acid of tungsten is a yellow powder; the method of procuring which, and its properties, have been already described under the denomination of yellow oxide of tungsten. It ought rather, as Vauquelin and Hechel have properly remarked, to be classed among the oxides than the acids; for it is insoluble in water, tasteless, and has no effect on vegetable blues. It agrees with the acids in the property of combining with salts, and perhaps also with some metallic oxides, and forms with them salts which have been denominated tungstates; but several other metallic oxides, those of lead, sliver, and gold, for instance, possess the same property. These oxides, therefore, may be called acids with as much propriety as the yellow oxide of tungsten.

The affinities of this oxide, as far as they have been ascertained, are as follows:

Lime, Soda, Barytes, Ammonia.

Magnesia, Barytes, Magnesia, Alginate, Potass, Zirconia.

The manner in which it was produced is evident: tungstic acid is composed of oxygen and tungsten; the oxygen combined with the carbon, and left the metal in a state of purity.

TUNICA, a kind of waistcoat or undergarment, in use amongst the Romans. They wore it within doors by itself, and abroad under the gown. The common people could not afford the toga, and so went in their tunics, whence Horace calls them populius tuniciata.

The several sorts of the tunica were the palama, the angustiaca, and the laticavia. The first was worn by generals in a triumph, and perhaps always under the toga picta; it had its name either from the great breadth of the clavi, or buttons, equal to the palm of the hand; or else from the figures of palms embroidered on it. It was by these three different sorts of tunics, that the three different orders of the Roman people were distinguished by it.

TUNNAGE. See Tonnage.

TUNNY. See Scomber.

TURBITHE, or TURBITHE-ROOT. See Convulvulus.

TURBO, the wreath, in zoology, a genus of insects belonging to the order of vernices testacea. The animal is of the small kind; the shell consists of one spiral solid valve, and the aperture is orbicular. There are 166 species: of which the most remarkable age, 1. The luffore, or periwinkle. This is abundant on most rocks far above low-water mark. The Swedish peasants believe that when these shells creep high up the rocks, they indicate a storm from the south. They are eaten by the poor people in most parts of this kingdom. Young lobsters are said to take up their lodgings in the empty shells of these animals, which has given occasion to a notion that periwinkles are changed into lobsters. But we apprehend the mistake to have originated from the circumstance of the cancer, or sooker-crab, which is a kind of small lobster or shrimp, naturally fleshed, which takes shelter in the cast shells of harboured shell-fish. 2. The clathrus, or barbel wreath, has a taper shell of eight spires, distinguished by elevated
divisions, running from the aperture to the apex. There is a variety pelliculoid, with very thin edges. It is too dense to form a curiously ornamental shell, the winkle-trap. See Plate Nat. Hist. fig. 411.

TURBOT. See Pluronectes.

TURUS, the thrush, a genus of birds belonging to the order of pigeons, they breed, but do not extend to the lower parts to feed on the berries of the mountainash. They migrate in France at the latter season; and appear in small flocks about Monthard in Burgundy, in the beginning of October, but seldom stay above two or three weeks.

To these we shall add the description of the orpheus, or mocking thrush, which is a native of America. It is about the size of a thrush, of a white and grey colour, and reddish bill. It is possessed not only of its own natural notes, which are musical and solemn, but it can assume the tone of every other animal in the wood, from the wolf to the raven. It seems even to sport itself in leading them astray. It will at one time allure the lessers birds with the call of their mates, and then terrify them when they come near with the screams of the eagle. There is no bird in Britain that is more heartless, and there is none that it has not at times deceived by its call. But, unlike such as we usually so famed for mimicking with us, and who have no particular merit of their own, the mocking thrush is by far the most itself. At those times it usually frequents the houses of the American planters; and sitting all night on the chimney-top, pours forth the sweetest and the most various notes of any bird whatever. It would also, if accounts are true, that the deficiency of most observant song-birds in that country is made up by this bird alone. They often build their nests in the fruit-trees about houses, feed upon berries and other fruits, and are easily rendered domestic. See Plate Nat. Hist. fig. 412.

TURIONES, among herbalists, denotes the first young tender shoots, which plants annually put forth.

TURRS. See MELEAGRIS.

TURRICICUS. See Cucumin.

TURMENT, or Turnament, a martial sport, or exercise, which the antient cavaliers used to perform to show their chivalrous courtesy.

TURNERA, a genus of the pentaehria, triginya class of plants, the flower of which consists of five petals obversely coriaded, and sharp-pointed; the fruit is an oval, unicellular capsule, containing a great many oblong and obtuse seeds. There are nine species.

TURNING, the art of forming hard bodies, as wood, ivory, or iron, into a round or oval shape, by means of a machine called a lathe. This art was well known to the ancients, and seems to have been carried by them to a very great degree of perfection; at least, if we believe the testimony of Pliny and several other authors, who tell us, that these precious vessels enriched with figures in relief, which still adorn our cabinets, were turned on the lathe. See Lathe.

The art of turning is of considerable importance, as it contributes essentially to the perfection of many other arts. The architect uses it for finishing the cornices of his halls and without finished houses. The mathematician, the astronomer, and the natural philosopher, have recourse to it, not
only to embish their instruments, but also to give them the necessary firmness and precision. In short, it is an art absolutely necessary to the goldsmith, the watchmaker, the joiner, and the smith.

Turning is performed by the lathe, of which there are various forms and several instruments, as gouges, chisels, drills, formers, and screw-taps, used for cutting what is to be turned into its proper form as the lathe turns round. See Plate Mixed, fig. 131; and Plate Lamp, figs. 6, &c.

The lathe should be fixed in a place very well lighted; it should be immovable, and neither too high nor too low. The puppets should neither be so low as to oblige the workman to stoop in order to see his work properly, nor so high that the little chips, which is continually driving off, should come into his eyes.

The piece to be turned should be rounded, (if it is wood) before it is put on the lathe, either with a small lathe made for the purpose, or with a plane, or with a file, fixing it in a vice, and shaving down till the piece is where almost of an equal thickness, and leaving it a little larger than it is intended to be when finished off. Before putting it on the lathe, it is also necessary to find the centres of its two end surfaces, and that they should be exactly opposite to each other, that when the pieces of the puppets are applied to them, and the piece is turned round, no side may belly out more than another. To find these, by putting a piece of wood to be turned upon a plank; open a pair of compasses to almost half the thickness of the piece, fix one of the legs in the plank, and let the point of the other touch one of the ends of the piece, brought into the same plane with the plank on which the compasses are fixed, and very near the fixed leg. Describe four arches on that end at equal distances from each other, at the circumference of the end, and one another within; the point of intersection is the centre of the end. In the same manner must the centre of the other end be found. After finding the two centres, make a small hole at each of them, and insert there two pieces of the puppets, and fix the piece so firmly as not to be shaken out, and yet loose enough to turn round without difficulty.

The piece being thus fixed, it is necessary in the next place to adjust the cord, by making it pass twice round the piece, and in such a manner, that the two ends of the cord, both that which is fixed to the spand and to the footboard, come off on the side on which the turner stands, that the piece may move against the edge of the cutting-tool and be turned. If the lathe is moved by a wheel, the manner of adjusting the cord needs no direction.

If the workman does not chance to be at the trouble to find the two centres of the piece in the manner described above, let him lay, as nearly as he can, the centre of one end upon the point of the left hand puppet, and then let him push forward the right hand puppet, striking it with a mallet till its point is in the centre of the other end of the piece; and then fixing the right hand puppet by a gentle blow of the mallet on the key, let him turn round the piece to see by the eye if the centres have been properly found. If any part of it bullies out, let him strike that part gently with the mallet, and it will correct itself. He should strike one of the puppets pretty smartly to drive the points into the piece, and afterwards fix the puppet by striking the key. If the workman cannot judge by the eye whether the piece is turning properly round its centres or not, he should apply gently the point of an instrument called a triangular graver, leaning it on the rest, and it will mark by a fine line the place where the piece is out of its centre; and by striking this line with a mallet, the piece can easily be placed properly. The rest, of which we have just spoken, ought to be placed upon the two arms of the lathe, and fixed with screws as near the piece as the workman pleases.

The piece being fixed between the two points of the puppets, the cord adjusted, and the rest fixed as near the work as possible without touching it; the workman is now to take a gouge of a proper size in his left hand, and hold it by the handle a little inclined, keeping the back of the hand lowermost. With his right hand, the back of which is to be turned upwards, he is to grasp it near the lower end, and when leaning the gouge on the rest, he is to present the edge of it a little higher than the horizontal diameter of the piece, so as to form a kind of tangent to its circumference; then putting the gouge on the footboard, and turning round the wheel, and holding the gouge firmly on the rest, the piece will be cut nearly in the same manner are the chisels, formers, and other instruments to be used, with the same care, and the operation of the piece by the instrument shall not be pushed improperly, sometimes stronger than at others; and taking care also, that the instrument used does not follow the work, but that it is kept firmly in the hand without yielding.

The young turner ought to endeavour to acquire the management of the gouge and the chisel, which are the instruments by far most necessary in this art; by them, almost entirely, are the soft woods turned; as for hard woods and other things, as box, ebony, horn, ivory, and the metals, they are hardly ever turned except by shaving off. In that case gravers are to be used with square, round, or triangular mouth. They should be held horizontally while applied to the wood, and not obliquely as directed for the gouge and the chisel.

After the work is completely turned, it is next to be polished, and this cannot be done with the instruments hitherto mentioned. Soft woods, as pear-tree, hazel, and maple, ought to be polished with a very soft Dutch or French rushes. There are different species of sharks; some of which have a grayish, others a reddish skin. Shark skin is always the better to be a good deal used; at first it is too rough for polishing. The Dutch rush is the equinoctial hydram of Limnes, which grows in most places among mountains. It is remarkable for having flinty particles in the substance of its leaves, which render it so useful for polishing. The Dutch rush is the material of a writing-pen. The oldest plants are the best. Before using them they should be moistened a little; otherwise they break in pieces almost immediately, and render it exceedingly difficult to polish with them. They are particularly desirable for glass, brass, iron, wooden figures, &c.; after having cleaned up the piece well, it should be rubbed gently either with wax or oil; then wiped clean and rubbed with its own filings for a couple of times, or with a cloth a little wet; by so doing, the iron, silver, gold, and brass, are polished with a micaceous easily pounded and put upon feather or a linen cloth a little moistened: with this the piece is rubbed as it turns round on the lathe; and to prevent any dirt from adhering to any part of it, every now and then it is rubbed gently with a small brush dipped in water. To polish very finely, the workman make use of tripoli, and afterwards of putty or calx of tin. Iron and steel are polished with very fine powder of emery; this is mixed with oil, and put between two pieces or very tender wood, and then the iron is rubbed with it. Tin and silver are polished with a burnisher, and that kind of red stone called in France saugine dune. They may be polished also with putty, putting it dry on shonamy-skin or with the palm of the hand.

To succeed in turning iron, it is necessary to have a lathe excessively well fixed, and the puppets, and exceedingly well fixed. The puppets should be short, and the rest well fixed very near the work; the back of the rest should be two or three lines lower than the iron to be turned.

The lathe and other instruments being prepared, it is necessary to determine the length and thickness of the iron to be turned according to the design which is to be executed, and to make it as thick of a stick as is the more convenient. In this case the importance is, that the iron being forged according to the model, it should be annealed, that is, heated red hot, and allowed to cool slowly on the coals till the foot goes out of itself. Some people, to soften the iron, cover it over with clay and allow it to cool. The iron cylinder being thus made, it is next to be put upon the lathe, finding the centres as formerly directed, and boring a small hole in them that the iron may not escape from the points.

The points should be left from time to time to prevent their being excessively heated and spoiled while the iron is turning. A crotchet is then to be applied to the iron, it is then to be turned a little above its centre, pretty gently, and by this means the inequalities of the cylinder will be taken off. Other instruments are then to be applied to round the iron according to the model; and whenever any of them grow hot, they are to be plunged into a bason of water lying beside the workman. If the iron, after being properly turned, is to be bored like a pen-point, one of the brass points is to be substituted in its place having a square hole through it, into which the collar of the iron is to be fixed firmly, so as not to shake; then borers are to be applied, like those
TURNING.

which locksmiths use to bore keys; and beginning with a small one, and afterwards taking larger ones, the hole is to be made as wide and deep as necessary; great care must be taken to support the piece firmly in the rest, otherwise there is danger of boring the hole straight. The borer must be withdrawn from time to time to oil it and to clean the hole. Since it is difficult to make a hole quite round with borer alone, it is necessary to have also an instrument a good deal smaller than the hole, one of the sides of which is sharp, very well tempered, and a little hollow in the middle. This instrument being fixed in a p'ty long handle, is to be applied with steadiness to the inner surface of the hole, and it will entirely remove every inequality that may have been there before its application.

For turning ovals, a lathe of somewhat a different construction is used. The axis or spindle, having on it the pulley over which the band-cord passes for turning the lathe, is fixed between the two puppets so as to turn round end of it passes through one of the puppets, and to it is firmly fixed a circular plate of brass, so that it turns round along with the spindle. Upon this plate two broad segments of circles are fastened, the circumference of which correspond to the circumference of the plate; their chords are parallel, and equally distant from the centre of the plate, so that they leave a distance between them. They have a groove in each of them, in which these grooves another plate is placed, which exactly fills up the space between the two grooves, but is shorter than the diameter of the larger circular plate on which it is laid. This plate is made to slide in the grooves. To its centre is annexed a short spindle, on which the piece of wood to be turned is fixed. When the lathe is set a going, the circular plate moves round, and carries the piece along with it; the plate of brass on which the piece is fixed, being fixed loosely in the grooves already described, slides down a little every time that the grooves become perpendicular to the floor (and there are particular contrivances to proceed with in the lathe so far), and by these two motions combined (the circular one of the large plate, and the straight one of the small), the circumference of the piece of wood to be turned necessarily describes an oval; and gores or other tools being applied in the usual manner, supported on the rest, it is cut into an oval accordingly. The small plate may be made to slide either more or less in the grooves; and by this contrivance the transverse diameter of the oval, or rather ellipse, may be made longer or shorter at pleasure. Another, and still simpler method if possible, of turning ovals, is this: Take two ovals of metal, exactly of the size of the oval which you intend to make; fix them firmly on the spindle of the lathe, so as to turn round with it; fix between them the wood to be turned, and then it is easy, by the help of chisels and other tools, to cut it, as the borer goes, into exactly the figure of the external avals. Or an oval may be formed by placing the wood, or whatever is to receive that shape, obliquely on the lathe. There are several other ingenious methods of turning, but these shall not detain us any longer on them. We shall therefore conclude this article with a number of receipts, which every turner ought to know.

1. The method of moulding boxes both of shell and horn. In the first place, form a proper piece of wood of any size, or pieces, viz., of a circle about half an inch thick, which should slope a little in order to draw out the moulded shell the more easily; and a ring fitted to the outside of the circle, so that both together make the shape of a box. These two pieces being adjusted, it is necessary to round the shell to be moulded of such a size, that when moulded, it will be a little higher than the ring of the mould, that there may be no deficiency. The mould is then to be put into a press on a plate of iron, exactly under the screw of the press; put then the shell upon the circle of the mould, so that its centre also is exactly opposite to the screw of the press; then take a piece of wood formed into a truncated cone, and not so thick as the diameter of the circle of the mould, nor so deep as the ring; then put a plate of iron above the cone, and screw down the press gently, and cautiously till the whole is well fast; then, plunge the whole into a cauldron of boiling water placed above a fire. In eight or ten minutes the shell or horn will begin to soften; screw the press a little more; then the wooden cone may sink into the softened shell; repeat this from time to time till the cone is quite sunk in the mould; then take out the press and plunge it into cold water. When it is cold, take the box from the mould, and put it into the incinerator, or it a new mould of exactly the form you wish the inside of the box to be; do the same with the outside, put it again into the press, and plunge it into boiling water; screw the press gradually till the box is fashioned as you desire.

2. Method of preparing green wood so that it will not split in the turning. Having cut your wood into pieces of a proper size, put it into a vessel full of a mixture of wood ashes. Boil it for a few hours, then take it from the vessel, and rub it with pulp of pine-stone; repeat this process a second time, and then rub the wood with the following composition: Put into a glazed earthen vessel a pint of strong vinegar, two ounces of fine filings, and half a pound of pounded galls, and allow them to inton[e] for three or four hours on hot cinders. At the end of this time augment the fire, and pour into the vessel four ounces of copperas (sulphat of iron), and a choping of water having half an ounce of borax and as much indigo dissolved in it; and make the whole boil till a froth rises. Rub several layers of this upon your wood; and, when it is dry, polish it with leather on which you have put a little flour of whiting.

3. Method of giving to plum-tree the colour of Brazil wood. Slack lime with urine, and bedaub the wood over with it while it is hot; allow it to dry; then take off the coat of lime, and rub it with chamois-skin well daubed with olive-oil, and then having a quantity of alum dissolved in it, five or six hours, keep lukewarm during a night; and when it is dry, rub it, as before directed, with chamois-skin well oiled.

4. Method of giving a fine black colour to wood. Steep your wood for two or three days in lukewarm water in which a little alum has been dissolved; then put a handful of logwood, cut small, into a pint of water, and boil it down to less than half a pint. If you then add a little indigo, the colour will more resemble that of the layer of that liquor quite hot on your wood with a pencil, which will give it a violet-colour. When it is dry, spread on another layer; dry it again, and give it a third; then boil verdigris at discretion in its own vinegar, and spread a layer of it on your wood; when it is dry, rub it with a brush, and then with oiled chamois-skin. This gives a fine black, and imitates perfectly the colour of ebony.

5. Method of cleaning and whitening bones before using them. Having taken with a saw the useless ends of the bones, make a strong lea of ashes and quick-lime, and into a pailful of this lea put four ounces of alum, and boil the bones in it for an hour; then take the vessel containing the lea off the fire, and let it cool; then take out the bones and dry them in the shade.

6. Method of soldering shells. Clean the two sides of the shells which you wish to join together; then, having joined them, wrap them up in linen folded double and well moistened; then heat two plates of iron pretty hot, that they may keep their heat for some time; and putting your shells rolled up between them under a press, which you must screw very tight, leave them there till the whole is cool, and they will be soldered. If you do not succeed the first time, repeat the process.

7. Method of moulding shells. Put six pints of water into a kettle; add to it an ounce of olive oil, or other oil; make the water boil; then put in your shell, and it will grow soft. Take it out, and put it into a mould under a press, and it will take the figure you want. This must be done quickly; for if you leave it cool, even so little, the process will fail. It will not work under pressure.

8. Method of tingling bones and ivory red. Boil shavings of scarlet cloth in water. When it begins to boil, throw in a quarter of a pound of ashes made from the drags of wine, which will extract the colour; then throw in a little of alum to clear it, and pass the water through a linen cloth. Sweep your ivory or bone in aqua fortis, and put it into the water. If you wish to leave white spots, cover the places destined for them with wax.

9. Method of tinge ivory black. Steep the ivory during five or six days in water of galls, with ashes made with dried drags of wine and arsenic; then give it two or three layers of the same black with which plum-tree is blackened in order to fix it; or dissolve silver in aqua fortis, and put into it a little rose-water. Rub the ivory with this, and allow it to dry in the sun.

10. Method of hardening wood to make pulleys. After finishing the pulley, boil it in a solution of gum in olive-oil, and it will become as hard as copper.

11. Method of polishing wood to make pulleys. After finishing the pulley, boil it in a solution of gum in olive-oil, and it will become as hard as copper.

12. To make Chinese varnish. Take of

TUS

gam-lac in grains four ounces; put it into a strong bottle with a pound of good spirit of wine, and add about the bulk of a hazel-nut of camphor. Allow them to mix in the sun, or on the hot embers for twenty-four hours, shaking the bottle from time to time. Pass the whole through a fine cloth, and throw away what remains upon it. Then let it settle for twenty-four hours, and you will find a thick layer of the upper part of the bottle, which you must separate gently and put into another vial, and the remains will serve for the first layers.

TURPNIKE, a gate set up across a road, watched by an officer for the purpose, in order to stop travel, vagrants, coaches, &c. to take toll of them towards repairing or keeping the roads in repair.

Justices of the peace, and other commission- ers, are authorised to appoint surveyors of the roads, and collectors of toll. In case any persons shall drive horses or other cattle through runways, to the highways, or to the turnpikes, they are liable to forfeit 10s. Likewise if any one assails a collector of the tolls, or by force passes through a turnpike-gate without paying, he is liable to forfeit 5l. leviable by justice of peace; and maliciously pulling down a turnpike is deemed felony, &c. It is also enacted, that 20s. shall be paid for every hundred that a carriage with its loading weighs above 6000 pounds weight, and that the fines may be set up at turnpikes for weighing such carriages.

TURPENTINE. See Pines, and RESINS.

TURRET, a genus of plants of the class and order decandria monogynia. The calyx is one-leaved, bell-shaped, five-toothed, very small, permanent. There are five species, shrubs of the East Indies.

TURTURIS, tuer-mustard, a genus of the tetradynamia silicosa class of plants, with a tetrapetalous flower; its fruit is an extremely long pod, containing numerous seeds. There are eight species. See Architecture.

TUSCULANO, colis foot, a genus of plants of the class symgenia, and order polyanisia superius; and in the natural system ranging under the 49th order, composita. The receptacle is naked; the pappus simple; the scales of the calyx equal, of the same height as the disk, and somewhat membranaceous. There are fourteen species, three of which are indigenous to Britain, the farfara, hybrid, and petasites. The farfar, or common calf's-foot, grows plentifully on the banks of rivulets, or in moist and clayey soils. The leaves were formerly smoked in the manner of tobacco, and a syrup or decoction of them and the flowers stands recommended in colds and other disorders of the breast and lungs. It seems now to be almost entirely rejected. The downy substance under the leaves, boiled in a lixivium with a little saltpetre, makes excellent tinder. The petals, or corolla, are detached in two orders in the Calyx, and are of different shapes. The leaves are the largest of any plant in Great Britain, and in heavy rains afford a seasonable shelter to poultry and other small animals. The root dug up in the spring is resinous and aromatic.

TYPANTUM, or Typan, in mechanics, a kind of wheel placed round an axis or cylindrical beam, on the top of which are two levers or fixed staves, for the more easy turning of the axis, in order to raise a weight required. The tympanum is much the same with the peritrophicus, but that the cylinder of the axis of the peritrophicus is much shorter, and less than the cylinder of the tympanum.

TYPANTUM OF A MACHINE, is also used for a hollow wheel, wherein one or more people, or other animals, walk to turn it; such as that of some cranes, calenders, &c.

TYPE, a copy, image, or resemblance of some model. This word is much used among divines, to signify a symbol, sign, or figure of something to come.

TYPE, among letter-founders and printers, the same with letter.

TYPES FOR PRINTING. In the business of cutting, casting, &c. letters for printing, the letter-cutter must be provided with a file, hand-vise, hammers, and files of all sorts for watchmakers' use; as also gravers and sculpters of all sorts, and an oil-stone, &c. suitable and sizeable to the several letters, to be cut: a flat gage made of box to hold a rod of steel, or the body of a mould, &c. exactly perpendicular to the flat of the using file: a sliding-gage, whose use is to measure and set off distances between the shoulder and the tooth, and to mark off from the end, or from the edge of the work; a face-gage, which is a square notch cut with a notch into the body of the piece of steel, iron, or brass, of the thickness of a piece of common tin, whose use is to proportion the face of each sort of letter, viz. long letters, ascending letters, and short letters. There must be three gages, and the gage for the long letters is the breadth of the whole body supposed to be divided into 42 equal parts. The gage for the ascending letters, Roman and
The founder must now be provided with a ladle, which differs nothing from other iron ladles but in its size; and he is provided always with ladles of several sizes, which he uses according to the size of the letters he is to cast. Before the caster begins to cast, he must kindle his fire in the furnace to melt the metal in the pan. He therefore takes the pan out of the hole in the stone, and there lays in coals and kindles them; and, when they are well kindled, he sets the pan in again, and puts metal into it to melt; if it is a small-bodied letter it casts, or a thin letter of great bodies, his metal must be very hot; may sometimes red-hot, to form a better circle. As soon as his ladle that holds about as much as the letter and break is, he lays it at the tucking hole, where the flame bursts out, to heat. Then he ties a thin leather, cut with its narrow end against the face to the leather-groove of the matrices, by whipping a brown thread twice about the leather-groove, and fastening the thread with a knot. Then he puts both halves of the mould together, and puts the runners and discs in and places the foot of the mould on the stool of the mould, and the broad end of the leather upon the wood of the upper half of the mould, but not quite up, lest it might hinder the foot of the matrices from sinking close down upon the stool in a train of work. Then laying a little resin on the upper wood of the mould, and having his casting-ladle hot, he puts the boiling side of it on the mould, and, while it is yet melted, he places the broad end of the leather hand down on the wood, and so fastens it to the wood: all this is the preparation.

Now he comes to casting: in the performance of which, placing the under half of the mould in his left hand, with the hook or hag forward, he clutches the ends of its wood between the lower part of the half of his thumb and his three hind fingers; then he lays the upper half of the mould upon the under half, so that the male gages may fall into the female gages, and at the same time the foot of the matrix places itself upon the stool; and, clasping his left-hand thumb strong over the upper half of the mould, he nimly catches hold of the bow or spring with his right-hand fingers at the top of it, and his thumb under it, and raising the handle of the notch in the backside of the matrices, pressing it as well towards the mould as downwards by the shoulder of the notch close upon the mould, with the same time with his handi-est and the deepest part of the mould towards he ball of his thumb, and thrusts by the ball of his thumb the upper part towards his fingers that both the registers of the mould may press against both sides of the matrix, and his thumb and forefinger press both halves of the mould close together.

He then takes the handle of his ladle in
right hand, and with the ball of it gives a stroke, two or three, outwards upon the surface of the molten metal, to scum or clear it from the film or dust that may swim upon it; then takes the half of a metal, and having his mould in his left hand, he a little twists the left side of his body from the furnace, and brings the heat of his ladle (till of metal) to the mouth of the mould, and twists the upper part of his hand towards him to turn the metal into it, while at the same moment of time he jits the mould in his left hand forwards, to receive the metal with a strong shake (as it is called), not only into the body of the mould, but while the metal is yet hot running, switl and strongly, into the very face of the matrixe, to receive its perfect form there, as well as in the shank.

He then takes the upper half of the mould of the under half, by placing his right hand thumb on the end of the wood next his left hand, and his two middle-fingers at the other end of the wood; and finding the letter and break lie in the under half of the mould (as most commonly by reason of its weight does), he throws or tosses the letter, break and all, upon a sheet of waste paper laid for that purpose on the bench, just a little beyond his left hand, and is then ready to cast another letter as before: and also, the whole number that is to be cast with that matrixe.

A workman will ordinarily cast about three thousand of the latter towards day.

When the casters at the furnace have got a sufficient number of types upon the tables, a set of boys come and nimblly break away the jets from them: the jets are thrown into the pots, and the types are carried away in parcels to other boys, who pass them swiftly under their fingers, deteled by leather, upon smooth flat stones, in order to polish their broad-sides.

This is a very dexterous operation, and is a remarkable instance of what may be effected by the power of habit and long practice; for these boys, in turning up the other side of the type, do it so quickly by a mere touch of the fingers of the left hand, as not to require the least perceptible intermission in the motion of the right hand upon the stone. The types, thus finely smoothened and flats, are on the broad-sides, are next carried to another set of boys, who sit at a square table, two on each side, and are ranged up on long runners or sticks, fitted with a small projection, to hinder them from slipping off backwards. When the sticks are so filled, they are placed, two and two, upon a set of wooden pins fixed into the wall, near the dresser, sometimes to the amount of a hundred, in order to undergo the finishing operations. This workman, who is always the most expert and skilful in all the different branches carried on at the foundry, begins by taking one of these sticks, and, with a peculiar address, slides the whole column of types off upon the dressing-stick:

this is made of well-seasoned mahogany, and furnished with two end-pieces of steel, a little lower than the body of the types, one of which is moveable, so as to approach the other by means of a long screw-pin, inserted in the end of the stick. The types are put into this stick with their faces next to the back or projection; and after they are adjusted to one another so as to stand even, they are then bound up, by screwing home the moveable end-piece. It is here where the great and requisite accuracty of the moulds comes to be perceived: for in this case the whole column, so bound up, lies flat and true upon the stick, the two extreme types being quite parallel, and the whole has the appearance of one solid continuous plate of metal. The least inaccuracy in the exact parallelism of the individual type, when multiplied so many times, would render it impossible to bind them up in this manner, by disposing them to rise or spring from the stick by the smallest pressure from the screw. Now, when lying so conveniently with the narrow edges uppermost, which cannot possibly be smoothed in the manner before mentioned by the workman does this more effectually by scraping the surface of the column with a thick-edged but sharp razor, which at every stroke brings on a very fine smooth skin, like polished silver; and thus he proceeds till in about half a minute he comes to the farther end of the stick. The other edges of the types are next turned upwards, and polished in the same manner. It is whilst the types thus lie in the dressing-stick, that the operation of hearing or breaking in is performed, which is effected by running a plane, faced with steel, along the shoulder of the body next to the face; which takes more or less off the corner, as occasion may require it. Whilst in the dressing-stick they are also grooved, which is a very material operation. In order to understand this, it must be remembered, that when the types are first broken off from the jets, some superficial metal always remains, which would make them bear very unequally against the paper whilst under the printing-press, and effectually mar the impression. That all these inequalities may, therefore, be taken away, and that the bearings of every type may be regulated by the shoulders impaled to them all alike from the mould, the workman or dresser proceeds in the following manner: The types being screwed up in the stick as before mentioned with the jet end uppermost, and projecting beyond the wood about one-eighth of an inch, the stick is put into an open press, so as to present the jet-end uppermost, and thus every thing is made fast by driving a long wedge, which bears upon a slip of wood, which lies close to the types the whole length; then a plough or plane is applied, which is so constructed as to embrace the projecting part of the types betwixt its long sides, which are made of polished iron. When the plane is thus applied, the steel cutter bearing upon that part between the shoulders of the types where the inequalities lie, the dresser dexterously glides it along, and by this means strips of every irregular part that comes in the way, and so makes an uniform groove the whole length, and leaves the two shoulders standing; by which means every type becomes precisely like to another, as to the height against paper. The types being now finished, the stick is taken out of the press, and the whole column replaced upon the other stick; and after the whole are so dressed, he proceeds to pick out the bad letters previous to putting them up into pages and papers. In doing this he lays the range into his left hand, and turning the faces near to the light, he examines them carefully; and whenever an imperfect or damaged letter occurs, he Nimby plucks it out with a sharp bodkin, which he holds in the right hand for that purpose. Those letters which, from their form, project over the body of the type, and which cannot on this account be rubbed on the stones, are scraped on the broad-sides with a knife or file, and some of the metal next the face pared away with a pen-knife, in order to allow the type to come close to any other. This operation is called kerning.

The excellence of printing-types consists not only in the due performance of all the operations above described, but also in the hardness of the metal, form, and true proportion of the character, and in the exact bearing and ranging of the letters in relation to one another. See PRINTING.

TYPOHA, cat's-tail, a genus of plants of the class monocotyledon, and order triandra; and in the natural system ranges under the 3d order, calmaria. The amentum of the male flower is cylindrical; the calyx is scarcely distinguishable; there is no corolla. The female has a cylindrical amentum below the male; the calyx is composed of villous hair; there is no corolla, and only one seed fixed on a papillary papus. There are two species, both natives of Britain; the latifolia and angustifolia. 1. Latifolia, great cat's-tail, or reed mace, is frequent in bogs and ditches. The stalk is six feet high, the leaves a yard long, jayndly an inch wide, convex on one side: the amentum, or cylindrical club, which terminates the stalk, is about six inches long, of a dark-brown or fuscous colour. Cattle will sometimes eat the leaves, but Schreber thinks them poisonous: the roots have sometimes been eaten in salads, and the down of the ament used to stuff cushions and mattresses. Limus or Russian cats-tail, is found in ponds and ditches. The leaves are semi-cylindrical, and the male and female spikes are remote and slender.

TYPOGRAPHY. See PRINTING.
U,
or V, the twentieth letter of our al-
phabets. In numerals V stands for five;
and with a dash added at top, thus V, it sig-
nifies five thousand. In abbreviations,
amongst the Romans, V. A. stood for Vete-
ranis assignati; V. B. viro bono; V. B. A. viri
boni arbitratu; V. B. F. vir bona fide; V. C.
vir consularis; V. C. C. F. vale, con-
pujx charissimus, felixiter; V. D. D. veto de-
dicatur; V. G. verbi gratia; Vr. Ve. virgo
vestalis; VL votidieci; V. N. quinto nonu-
rum.

VACCINATION, in law, is the whole time
between the end of one term and the begin-
ing of another.

This word is also applied to the time from
the death of a bishop, or other spiritual per-
son, till the bishopric, or dignity, is supplied
with another.

VACCINATION. Inoculation with the
vaccine virus, for the purpose of securing
against the infection of the small pox.

This subject cannot fail to " come home to
the business and bosom" of every one; for
where is the individual of such slender con-
nection or limited sympathies, as to be indif-
ferent to a question which "involves the
lives annually of 40,000 in Britain alone,"
and of the same proportion throughout the
civilized world?

It would be superfluous, then, to apologize
for making the vaccine controversy a subject
of separate and prominent discussion.

We shall first lay before our readers a ge-
neral history of the circumstances which led
to the introduction of the new, as a substi-
tute for the old, inoculation; we shall then
enumerate the advantages which vaccination
lays claim to, canvass the objections which
have been made to the admission of such
claims, and conclude by describing the gen-
eral characteristics of perfect, and marks de-
noting spurious, cow-pock infection.

It is scarcely necessary to acquaint any
reader by whom the first public proposal was
made respecting the cow-pox inoculation.
Dr. Jenner, while employed in the practice
of surgery in a district of Gloucestershire,
was surprised to find that many individuals
whom he was called upon to inoculate, re-
sisted every attempt to infect them with the
small-pox virus. Upon enquiring into the
occasion of this extraordinary immunity, he
learnt that those in whom it existed had pre-
viously undergone a disease contracted by
milking cows affected with a peculiar erup-
tion on their teats. "It appeared (says
Dr. Jenner) that this disease had been known
among the dairy-maids from time immemo-
rial, and that a vague opinion prevailed that
it was a preventive of the small pox. This
opinion I found was comparatively new
among them; for all the old farmers declar-
ed they had no such idea in their early days:
a circumstance which seemed easily account-
ed for, from my knowing that the common
people were formerly rarely inoculated for the
small pox, till that practice was rendered gen-
eral by the improved method introduced by
the Suttons; so that the working people in
the dairies were seldom put to the test of the
preventive power of the cow-pox."

In prosecuting his enquiries, Dr. Jenner found it to
be an unanimous opinion among medical prac-
titioners in the neighbourhood, that the dis-
ease thus contracted from the cow was by no
means to be relied on as a security against va-
rilous infection; an opinion which he was at
first concerned to find apparently well found-
ed by the occurrence of the latter, in some
individuals, who had been, as was imagined,
supplied to the former.

This discouraging circumstance, although it
angered the ardour of Dr. Jenner, did not oc-
casion the abandonment of his investigation:
and he was shortly gratified in ascertaining
that the cow was subject to several varieties
of eruption on her teats, all capable of pro-
ducing ulcerations on the hands of the mil-
kers, but not of insuring against the infection
of small pox. This discovery removed the
great obstacle to his interesting research, and
our experimentalist was the first to distin-
guish and divide the genuine from the spuri-
ous cow-pox.

His expectations of success were a second
time impalpable, by finding that even among
those who had been infected with the genu-
ine virus, some were afterwards obnoxious to
the small-pox contagion; and this difference
of subsequent susceptibility was even witness-
ed in different individuals who had received
the infection from the same animal.

It required no common share of persever-
ance still to abide by the object of pursuit af-
ter this seemingly almost insurmountable im-
pediment to success. Dr. Jenner, however,
was engaged in an undertaking of too much
magnitude and moment to abandon it, unless
from absolute necessity, and he still per-
severed.

It occurred to him that the specific prop-
erties of the cow-pox matter might vary with
its progressive changes after secretion; and
putting this likewise to the test of experi-
ment, the result coincided with his conjec-
ture, affording an explanation of this second
anomaly equally clear and satisfactory with
the former. He found, by repeated trials,
that the genuine or preventive disease was
only capable of being engendered by the mater-
ial from the ulcer in its earliest stages:
that when from continuance it had undergone
certain decompositions, it was no more capa-
ble of producing the true cow-pox than the e-
ruptions of which we have already spoken.
With these restrictions, Dr. Jenner found that
the immunity, from the variolous occasioned
by the vaccine infection was for life; at least
individuals without any effect were subjected
to the former after the lapse of 15, 27, and
even 50 years from the latter infection.

During this very curious and important in-
vestigation, Dr. Jenner was struck with the
idea that the preventive he had discovered of
small-pox contagion might be propagated
from one individual to another in the manner
of variolous inoculation, and for this supposi-
tion it does not seem improper to notice that
he had, in one sense, the authority of analo-
gy beyond that which could be claimed by
the first ingrafters of variola; for the natu-
ral vaccine distemper is itself produced by
a species of inoculation, which it is well known
is by no means the case with the natural
small pox.

We have stated this circumstance not from
a desire to prejudice the question of the com-
parative merits of the variolous and vaccine
diseases. It is the duty of every one, it is
our especially and officially, to state argu-
ments and facts as we find them, whether in-
trinsic, or in favour of, either one or the
other practice.

In pursuance of the plan we have above
laid down, we now proceed to give as con-
crated a view as possible of the supcrior
advantages contended for by the advo-
cates of inoculation for the cow-pox.

These we shall principally extract from a
popular work on vaccinia, by Dr. Thornton,
and of the most ardent and effective support-
ers and propagators of the new discovery.

1. It is maintained that the constitutional
affection which cow-pox produces, is incom-
parably milder than that from variolous in-
oculation. The proportion of deaths from
inoculated small pox is stated by Dr. Willan
to be 1 in 230. The zealous antivaccinators
have denied it to be greater, under judicious
treatment, than 1 in 1000. In the pre-
zent, as in other instances, we leave the
reader to select his own authority. We have
only to add, that we believe the mortality at
all of the vaccine distemper, in an immate-
direct manner, has not been contended for.
This first proposition, then, in favour of
the vaccine disease, is amply contested.

2. The cow-pox never disfigures the cou-
ument. Of this, likewise, there is no dis-
pact, as it refers to the distemper merely;
indisputably of the supposed consequences of
it, which we are shortly to convey.

3. The cow-pox may be introduced into
the system without any apprehension of con-
sequences, under circumstances which render
even the inoculated small pox, in some measure,
dangerous, such as the periods of teething, of
pregnancy, and of advanced age. The pro-
position we believe to be likewise too well
founded, and generally admitted to need sub-
stantiating by examples.

The cow-pox inoculation does not, like
that of the small pox, disseminate the disease
VACCINATION.

It is not infectious. This is a most material circumstance in favour of the new inoculation; and is an undisputed fact that the mortality of small pox has increased since the adoption of an artificial mode of communicating it, though many individuals have profited by inoculation, it has produced more lives in the aggregate, than it has preserved; and has aggravated the sufferings of those who have been compelled to employ it, in a greater degree than it has relieved those who have avoided them.

5. The cow-pock does not leave any bad umours after it.

6. "Its security, as a prophylactic against small pox, is equal to the small pox itself, neither natural nor inoculated."—Thomson.

Under these six heads we believe that we have included all the benefits which are stated or implied to have resulted from the Jennerian practice by its several advocates; and we apprehend it only in the two last particulars that any material difference of sentiment now prevails among those who are still adverse to vaccine inoculation. It seems to us to be a gratuitous concession that, for the reasons now stated, Jenner's discovery, from an apprehension of an unjustifiable interference with the decree of Providence, we should not only be compelled likewise to abandon various inoculations, but we ought to be prepared to retard the progress of fever, of mitigating the violence of pain, or of extracting a carbuncle.

It is then the two last propositions which demand a separate and particular investigation.

First, Does the cow-pock engender other diseases? or, in the phraseology before used, does it leave any humours after it?

It is necessary to observe, that those gentlemen who have opposed against inoculation, and who have introduced other diseases, have described these affections to be principally cutaneous. Now those who aver that this is an absolute misrepresentation; and that so far from the cow-pox engendering the above mentioned diseases, the number of scrofulous and cutaneous disorders which have followed upon the small pox, naturally and artificially introduced, are in a greater proportion than those which have happened posterior to vaccine inoculation: are much more numerous than the advocates for the contrary side of the question. On this ground, then, the inference from every principle of reasoning would be drawn by an impartial judgment in favour of vacination; but not, we hope, by the antivaccinists, who are constituted as irregular or unfair, to appeal on this to a particular authority, viz. Dr. Willan, who, if he has no title to be considered as "the oracle of the metropolis in all cutaneous diseases," has unquestionably a right to speak on this head "as one having authority." This gentleman asserts that no new disorders have been introduced since the discovery of vaccine inoculation, and that the cutaneous affections which had been previously prevalent have in no measure increased in virulence. But Dr. Willan, it will perhaps be urged, may be a prejudiced, and therefore an incorrect judge. Aware of the possibility of such an objection to the practice merely in order to authorize his assertion, but has inserted in his treatise Dr. Bateman's extract from the register of patients at the public dispensary in London.

In the year 1797, before the publication of Dr. Jenner's enquiry, the total number of diseases was 1730; the number of chronic cutaneous eruptions was 82. In 1798, total number of diseases 1863; chronic cutaneous eruptions 82. In 1804 the proportions are 135—29. In 1805, 190—16. We distinctly state the same proportion, our author adds, may be deduced on comparing Dr. Murray's, Dr. Reid's, Dr. Walker's, and my own reports on diseases in London for the last ten years: and these, it may be added, were made without any reference to the vaccine controversy. Ought, then, the individual cases brought forward by the gentlemen opposed to vaccination to outweigh, or even balance, the contrary evidence above adduced? Here again, we leave the reader to make his own inference.

If it should be urged that we have not brought forward the cases opposed to vaccinia, it is answered, neither have we adduced the more numerous instances which make against the various inoculations. In fact, the uncertainty of medical evidence forbids any satisfactory conclusion but that which is deduced from comparison on a large and general scale.

It would be, however, doing injustice to the cause of vaccination, to omit the following statements from Mr. Trye, surgeon to the Gloucester infirmary: 1st. "A more healthy description of human beings does not exist, nor more free from chronic cutaneous impurities, than those which suffer most from cow-pox, by reason of their being employed in dairies.

2d. "The Gloucester infirmary, one of the largest provincial hospitals, is situated in a county in which accidental cow-pox has been prevalent from time immemorial. Many hundreds among the labouring people have had the cow-pox since the establishment of that institution, and more severely than generally the case in artificial vaccination; and yet not a single patient in half a century, has applied to the infirmary for relief of any disease, local or constitutional, which he or she imputed or pretended to trace to the cow-pox. And let it be repeated and remembered, that the artificial in no respect differs from the accidental cow-pox, except in being generally less virulent."

But the most momentous question still remains to be discussed. Does the cow-pock afford a permanent security against various infections?

Towards the decision of this point it will be found of essential consequence to revert to the two obstacles which we have already stated, as having presented themselves to Dr. Jenner in the commencement of his investigation.

While the reader retains this in mind, he will readily, we think, perceive the self-evident conclusion contained in the following remarks of Dr. Rowley: "No other questions are admissible in vaccination than, Have the parties been inoculated for the cow-pox? Yes. Have they had the small pox afterwards? Yes. As to how, when, where, whether the cow-pox tool, was genuine or spurious, or any arguments, however specious, as pretences for doubts or failures, they are evasive or irrelevant to the question. They may confound fools, but do not heighten the credit of vaccination."

On this declaration it has been forcibly remarked, that "it would be less absurd to convict a jury in a trial for murder, that the only question was, whether a pistol had been fired or not; and that it was of no consequence to inquire whether it was loaded with ball, or whether the sufferer had died of a pistol-shot."

After what we have already stated respecting those emulations which have been indiscriminately thought the same as the true vaccine disease, and of the changes which the cow-pox matter is itself susceptible of, we think our readers will unite in opinion with us, that the only questions to interest are genuine or spurious cow-pox, "the how, the when, and the where" the parties were inoculated, are material points to ascertain, as preliminary steps to decision respecting alleged failures.

By the further statement which will be given in the sequel, it will be perceived that there are several circumstances necessary to the perfection and absolutely preventive power of vaccine inoculation, which it is by no means unlikely should be overlooked, or unknown to, the inoculators in the early periods of the practice. "During the years 1799 and 1800, vaccine inoculation was performed by ten or twelve thousand persons who had never seen the vaccine pasteure." (Dr. Wil
an.) Now, under these circumstances, we cannot help agreeing with this author that it is rather matter of surprise that the number of unsuccessful cases has proved so comparatively small.

Here it is material to observe, that the majority of those examples which have been brought forward as examples of various, after vaccine disease, have been attended with so much irregularity, that they cannot be considered as instructive to the practice.

This we think, has been rendered evident by the very able and dispassionate examination of Dr. Willan on the progress and termination of the most formidable of such cases as have occurred in and about the metropolis.

But let it be granted to the opponent of vaccination, that several instances have been presented of perfect and regular small pox subsequent to the vaccine disease, equally genuine and regular, "yet still the Jennerian practice must maintain its ground triumphantly, if it can be shown to be as effectual a preventive of small pox as the old inoculation."

Now we think it has been demonstrated beyond the possibility of contradiction, that the number of authenticated cases of small pox after the old inoculation, and even after a former attack of the natural disease, are more numerous in proportion than those that are alleged with any probability of such an event after cow-pox inoculation.

The writer of the article from which we have extracted the above observations, goes on to say: "On the whole, we think there are not fewer than twenty distinct
cases of small pox, occurring a second time in the same subject, each of them authenticated far more completely than any one that has been cited by the adversaries of vaccination. We are persuaded, indeed, that we shall be supported by every impartial person who makes the first step of the whole practice, in saying, that there are not so many as ten cases of small pox, after perfect vaccination, proved in such a way as to be entitled to any sort of attention. Now the medical council, consisting of almost all the great practitioners in London, have reported that nearly as many persons have been already vaccinated in this kingdom, as were ever inoculated for the small pox since the first introduction of that practice; so that if the two cases were exactly upon a footing, the risk of failure seems to be at least twice as great in the small-pox inoculation as that for the cow-pox. And yet who is there in the present day who thinks for a moment of alleging possible insecurity as an argument against variolous inoculation? It may be instructive to state that this argument was however used against the old at the time of its introduction, and was urged much in another connexion by another against the new. Dr. Wilson and others, in their respective treatises, have cited many examples of the mode in which the variolous controversy was carried on, a single one of which our limits will only permit us to extract.

"I fear they may be accounted physicians of no value and worthies of lies, who so confidently tell us what it is impossible for them to know, namely, that they who have tried the experiment (the inoculation for small pox) are for ever thereby secured from any future danger of infection." Page 18, Rev. Mr. Mason's sermon against the dangerous and sinful practice of inoculation.

Against the suggestion of Mr. Goldston, that, although the natural cow-pox may secure from variolous infection, the inoculated disease may be more precarious and uncertain, we think it of common place, that were the variolous and vaccine inoculation to be judged and compared a priori upon the ground of analogy alone, the latter would have the fairest pretensions to prevail; but now that the variolous cow-pox, we have already said, are ingrained upon the system in nearly a similar manner; in the instance of variolous infection, this is not the case. Further, the vaccine matter, whether taken directly from the cow, or from the arm of an inoculated person, produces an affection which is not so generally dissimilar as the ingrained and naturally received small pox; what authority then have we for insisting that the virus undergoes that specific change in the human body, which the theory of Mr. Goldston supposes? If then permanence of security is allowed to the natural (and the admission of this, from a man of such ability and candour as Mr. Goldston, is exceedingly material), we cannot but suppose it repugnant to every principle of analogy, to deny it to the inoculated cow-pox.

It is necessary to remark, that the cases which have been collected and recorded, do by no means serve to strengthen the suspicion of immunity for a given time; for the utmost irregularity has been shown, with respect to the period of variolous subsequent to vaccine infection. "The cases," says Dr. Willam, "which I have had occasion of various eruption, took place without any certain order, from five months to seven years after vaccination. If it is said that the preventative power of the cow-pox ceases after one year, it is quite true that sometimes the exit of a matter in two, or three, and to four years; but experience has fully established the falsity of these assumptions, and the most determined sceptic no longer talks of temporary immunity from variolous inoculation.

To urge the argument farther against the doctrine of partial and limited security, would be, we think, superfluous; unsupported by analogy, and unsustained by fact, it falls more suitably.

We now proceed to extract from Dr. Willam's treatise the characteristics of perfect, and marks of spurious, vaccination.

"Vaccination," says our author, "is accounted perfect, when recent lymph has been carefully inserted beneath the cuticle, in a person free from any contagious disorder; and has produced a small, pearl-coloured vesicle, which, after the ninth day, is surrounded by a red areola, and afterwards terminates in a hard dark-coloured scar.

The form and structure of this vesicle are peculiar; its base is circular, or somewhat oval, with a diameter of about four lines on the tenth day. Till the end of the eigtht day, its upper surface is uneven, being considerably more elevated at the margin than about the centre, and sometimes indicated by one or two concentric furrows; but on the ninth or tenth day, the surface becomes plane, and in a very few instances, the central part is highest. The margin is turgid, firm, shining, and rounded so as often to extend a little beyond the line of the base.

"The vesicle consists internally of numerous little cells, filled with clear lymph, and communicating with each other. The areola, which is formed round the vesicle, is of an intense red. The cuticle, or the outer skin, differs from that of two inches, and it is usually attended with a considerable tumour and hardness of the adjoining cellular membrane. On the eleventh and twelfth day, as the areola declines, the surface of the vesicle becomes brown in the centre, and less clear at the margins. The cuticle then begins to separate, and the fluid in the cells gradually congeals. The excreta consists of a redish-brown colour. The scab becomes at length black, contracted, and dry, but it is not detached until after the twentieth day from the inoculation. It leaves a permanent circular cicatrix, a little depressed, the surface being marked with very minute pits or indents, denoting the number of cells, of which the vesicle has been composed."

To such general characteristics of perfect vaccination. * Imperfect vaccination is not characterised by any uniform sign or criterion, but exhibits in different cases very different appearances, as pustules, ulcerations, or vesicles of an irregular form. The vaccine pustule is considoral; it increases rapidly from the second to the fifth or sixth day, when it is raised on a hard inflamed base, with diffuse redness extending beyond it on the skin. It is usually broken before the eighteenth day, and is soon after succeeded by an irregular brownish scar. The redness disappears in a day or two, and the tumour gradually subsides. Vaccination is imperfect or insufficient, 1. When the fluid employed does not contain any of its original properties. 2. When the persons inoculated were soon afterwards affected with any contagious fever. 3. When they are affected at the time of inoculation, with some chronic cutaneous disorders.

1. The qualities of the vaccine fluid are altered, soon after the appearance of an inflamed areola round the vesicle; and the fluid, although taken out of a vesicle in the best possible state, may be injured by heat, exposure to air, rust, moisture, and other causes.

2. When scales are formed over various pustules, and vaccine vesicles, the matter they afford is often acrid and putrescent; and it is frequently observed that the excreta vanishes as if it were before the operation of anatomy, that matter improperly kept, or the thick matter from collapsed and scabbed various pustules, and used for the purposes of inoculation, does not always produce the small pox, nor prevent the future occurrence of that disease, although the persons inoculated may have had inflammation and suppuration of the arm, and pains in the axilla, with fever and eruptions on the ninth or tenth day following. The vaccine fluid employed is taken at a late period, as from the twentieth to the eighteenth day, it does not always produce the genuine cellular vesicle, but in some cases wholly inefficacious; and in others, it is not productive of any ulcer or ulceration, in others an irregular vesicle, and in others erysipelias. Failures may have been occasioned by repeatedly puncturing or draining the vesicle, on two or three successive days.

3. When the cutaneous diseases which sometimes impede the formation of the genuine vaccine vesicle, are herpes (including the shingles, and vesicular ring-worms), the dry and the humid tetter, and the itch; but especially the porrigio (or time), comprising the varieties denominated crustaceous, are, scroches, and fatti, all of which are contrary to those that would perhaps be added the itch and porrigio.

"The right inference," our author in another part of his treatise observes, "from the mistakes or failures, and from the nicety of vaccine inoculation, is, that those only
should be inoculators, who have had a sufficient education, and who have particularly attended to the subject of vaccination." Dr. Wilian then goes on to enforce the propriety of a strict examination, and in dubious cases a reinoculation, of those persons especially who were inoculated at the 1st of Janu-
ary, 1799, and the 1st of January, 1802.

We are under the necessity of stating, that in the present article we have appealed principally to the authority of Dr. Wilian, not merely on account of the interest and universally acknowledged value of such authority; but because this gentleman, being neither an inoculator nor a partisan, cannot fail to be acquitted even by those who are least disposed to liberality of sentiment, of being in any measure influenced by the motives charged upon vaccinators in the following sentences, which, the reader will be surprised to find, are the composition of a learned, sagacious, and most respectable physician:

"The cow-pox inoculators who have been principals, reproach one another as not having the genuine matter, or skilful management, of vaccinating; the labourers in the same vineyard are wrong. If the small pox happens after Peter's operation, James, Paul, and John, are not all surprised; if from James, Paul, or John, disease happens, Peter says it is what he expected. Each pretends to some superior mystery over his brother-vaccinator. Each leader seems to say, —Come to my shop; this is the only true booth in the fair; that booth is the next true one." (Dr. Mosley.)

It would be unjust to conclude without admitting the only shadow of justification, which such language can claim; namely, the equal and perhaps prior interference of medical writers, on the opposite side of the question. We cannot forget the mode in which Mr. Goldstone's first candid and dispassionate inquiry into the merits of vaccination, was referred to by vaccinators; and every rancour ought at least to be excluded from this subject of universal interest.

VACCINIUM, the Whortle-berry, or Brieberry, a genus of plants of the class Vaccinacea, comprises the berries ranges in the natural system under the 18th order, bicorns. The calyx is superior; the corolla monopetalous; the filaments inserted into the receptacle; the berry quadri-locular and polymerspermous. There are 27 species, the most remarkable of which are:

1. The myrtus, black-berets, whortle-berries, or bilberries, growing in woods and on heaths abundantly. The flowers vary much in size, between 5 and 10 inches long, and with a sweet benzal smell. It was discovered by the duke of Aethol, growing in the woods about a mile and a half between his two seats of Dunkeld and Blair. The berries have an astrignent quality. In Arran and the Western Isles they are given in diarrhœas and dysenteries with good effect. The Highlanders frequently eat them in milk, which is a cooling agreeable food; and sometimes they are mixed with whisky, which last they mix with whisky, to give it a relish to strangers. They dye a violet-colour; but it requires to be fixed with alum. The grouse feed upon them in the

VAG 863

autumn. 2. The euonymus, or great berr- 
bery-bush, is found in low moist grounds, and almost at the summits of the Highland mountains. The leaves are full of veins, smooth and glaucous, especially on the under side; the berries are eatable, but not so much relished as those of Vaccinium. They are apt to be sour if eaten in any quantity, to give the head-ache.

3. The vitis idea, or red whirl-berry, frequent in dry places, in heaths, woods, and on mountains. The berries have an acid cooling quality, useful to quench the thirst in fevers. The Sweedes are very fond of them made into the form of a roll or jelly, which they eat with their meat as an agreeable acid, proper to correct the animal alkali.

4. The oxycoccus, cranberries, moonbe-
"Candida, true vinifera, for juice, each of them might be turned into the vineyard; are as useful as the best of vineyards now."

VAGINAS, a genus of birds of the order grallæ: the generic character is, bill strong, thick, conico-convex, compressed; the upper mandible covered above with a movable horny sheath; nostrils small, placed behind the beak; tongue above found, beneath flattened, pointed at the tip; face naked, papillous; wings with an obtuse excrescence under the flexure: legs strong, four-toed, naked a little above the knee, one of the four being grooved. There is but a single species, which inhabits New Zealand and the South Sea islands, from 15 to 18 inches long, and feeding on shell-fish.

VAGRANTS are divided into three classes: 1st. Idle and disorderly persons. These, as described by the vagrant-act, consist of those who threaten to run away and leave their wives and children to the parish. All persons returning to a parish whence they were removed within the space of 6 months, are bringing a certificate from the parish to which they belong. All who, not having wherewith to maintain themselves, refuse to work. All who beg alms from door to door, or in the streets and highways. Likewise those who, not using proper means to get employment, or possessing ability to work, refuse to do it; or spend money in alehouses, or in any improper manner; and by not employing a proper proportion of the means of their livelihood, of their families, suffer them to become chargeable to the parish.

The punishment for these offences is a commitment to the house of correction, and hard labour, for any definite time not exceeding six months; and the time must be set forth in the warrant of commitment, which must also shew the authority of the person committing. The commitment must be in execution, that is to say, for punishment; and being so, the justice must make a record of the conviction, and of the处sions. Any person may apprehend and carry such persons before a magistrate; and if they resist or escape, they shall be punished as rogues and vagabonds: the reward for such apprehension is $50, to be paid by the overseer of the parish.

2. Rogues and vagabonds. No infant under the age of seven years can be called a rogue and vagabond, but shall be removed to its place of settlement, like other paupers.

The following is a list of those who are deemed rogues and vagabonds: All persons gathering alms under pretended losses; persons going about as collectors for prisons or hospitals; judges; beavers; common players not legally authorised; mistrels; jugglers; or real or pretended gypsies, fortune-tellers; any persons using any craft to impose upon any of his majesty's subjects, or playing at unlawful games, or any who have run away and left their wives and children; any vagabond, and all petty chapmen and peddlars not authorised by law; all persons not giving a good account of themselves; all beggars pretending to be soldiers or seamen, or pretending to go to work in harvest; or illegal dealers in lottery tickets and shares. And all other persons wandering abroad and begging, shall be deemed rogers and vagabonds; the reward for apprehending such persons is $50, to be paid by the high constable, on an order from the justice. There is a penalty of $10, on a constable who refuses or neglects to apprehend them.

3. Incongruous rogues, are all end-gatherers, offending against the statute. 3d Geo. 2d; which is collecting, buying, receiving, or carrying, any ends of yarn, with the intent to sell, or other refuse of cloth or woollen goods. All persons apprehended as rogues and vagabonds, and escaping, or refusing to go before a justice, are not to be enforced to be taken by the pass, or given a false declaration of themselves on examination, after warning. All rogues or vagabonds escaping from the house of correction before the expiration of the time of their commitment; and all who have been punished as rogues and vagabonds, and repeat the offence.

There is by 17 Geo. I. c. 25, a privy search appointed; and the justices or two of them four times a year at least meet, and commit the principal rogues or vagabonds, or their personal and movable estate, to be taken and brought to the house of correction. The rogues and vagabonds are examined upon oath as to their parish,
the written examination signed by them and the justice, and transmitted to the sessions.

The punishment is public whipping, or confinement to the house of correction till the next sessions, or any less time; and if at the sessions a court adjudi- cates a person a rogue and vagabond, or an incorrigible rogue, they may order such rogue or vagabond to the house of correction and hard labour for six months, or such incorrigible rogue for not less than six months or more than two years, and during his confinement to be whipped as they shall think fit. And if such rogue or vagabond is a male above 12 years old, the court may, after his confinement, send him to be employed in his ma-

jesty's service: and if such incorrigible rogue shall make his escape, or offend a second time, he shall be transported for seven years. After such whipping or confinement, the justice may, by a pass under his hand (of which a duplicate shall be filed at the next sessions), cause him to be conveyed to the place of his last legal residence, and if that cannot be found, to the place of his birth; and if they have fourteen or more children, and have parents living, then to the place of their abode; and the parish to which the vagrant shall be conveyed, shall employ him in some workhouse till he gets some employment. Their sufferings, which were severe, should be sent to the house of correction and hard labour.

The general tenor of the laws respecting vagrants, is extremely severe, and very just; for the purpose of preventing the peace to keep his district free from this class, as they are great burthens to the parish, and very difficult to be removed. For the best account of the vagrant-act, vide Barn's Justice, vol. 4, article Vagrant.

VAHILIA, a genus of plants of the class of the order perenandria, the cymals is five-leaved; corolla five-petalled; capsule inferior, one-celled, many-seeded. There is one species, a herb of the Cape.

VALANTIA, a genus of plants in the order monocotyledon, of the class polypodium, and in the natural system arranged under the 41st order, the super-polypodium. There is scarcely any certain demarcation of species, the chief characters being the length of the cymals, and one seed; the pistil of the male flowers are rarely discernible. There are 9 species, only one of which is a native of Britain, the crenulata; the stalks of which are square, the whole plant hairy, the leaves oval and verticillate, four in a whorl; the flowers are yellow, and grow on short peduncles out of the axil of the leaves. The roots, like those of the galingale, to which it is nearly related, will dye red. It is astrin-
gent, and was once used as a vulnerary.

VALENTINANS, in church history, a sect of Christian heretics, who sprang up in the second century, and were so called from their leader Valentinus. The valentinians were only a branch of the gnostics, who rea-
lized the Platonic ideas concerning the Deity, whom they called Pleroma, or plentitude. Their system was this: the first principle is Bythus, i.e. depth, which remained many ages unknown, having with it Emena, the light, and Siga, or silence; from these sprung the Nour, or intelligence, which is the only son, equal to, and alone ca-

pable of comprehending: the Bythus, the sister of Nour they called Aletheia, or truth; and these constituted the first quan-
ternity of roots, which were the source and origin of the world. For Nour and Ale-
then produced the world, and life, and from these two proceeded man and the church. But besides these eight principal roots, there were twenty-two more, the last of which, called Sophia, being desirous to arrive at the knowledge of Bythus, gave herself a great deal of uneasiness, which created in her anger and fear, of which was born matter. But the Floros, or boundary, stopped her, pre-

served her in the Pleroma, and restored her to perfection. Sophia then produced the Christ and the Holy Spirit, which brought the zoos to their last perfection, and made every one of them contribute their utmost to form the Saviour. Her Ethynese, or thought, dwelling near the Pleroma, perfect-
ed by the Christ, produced every thing that is in the world, by its divers passions. The Christ sent unto it the Saviour, accompanied with angels, who delivered it from its pas-
sions, converted it into the Pleroma, and thence was formed corporeal matter.

VALENZANA, a genus of plants, of the class triandria and order monandria, and in the natural system arranged under the 48th order, the super-triaandria. There is hardly any certain species; the corolla is monopetalous, gibbose at the base, situated above the germen; there is only one seed. They are 31 species, of which six are natives of Britain, the officinalis, the rubra, and the diocia; of these only the officinalis is useful.

The root of this plant is ptenial; the stalk is upright, smooth chambered, round, branch-
ed, and rises from two to four feet in height; the leaves on the stem are placed in pairs upon short broad sheaths; they are compose-
d of several lance-shaped, partially dentated, reined, smooth pinnas, with an odd one at the end, which is the largest: the floral leaves are spine-shaped and pointed: the flowers are small, of a white or purplish colour, and terminate the stem and branches in large

bunches. It flowers in June, and commonly grows in hedges and woods.

It is supposed to be the vp of Dioscorides and Galen, by whom it is mentioned as an aromatic and diuretic: it was first brought into estimation in convulsive afections by Fabius Columba, who relates that he cured himself of an epilepsy by the root of this plant; we are told, however, that Columba suffered a relapse of the disorder; and no further accounts of the efficacy of valerian in epilepsy followed till those published by Do-

minica Perrier, fifty years afterwards, in which three cases of its success are given.

The advantages said to be derived from this root in epilepsy, caused it to be tried in several other complaints termed nervous, particularly those produced by increased mo-

bility and irritability of the nervous system, in which it has been found highly serviceable. Bergius states its virtues to be anaphrodisiac, diuretic, emmenagogue, diuretic, anthel-

mintic, in substance is putrid, and is usually given in powder from a scruple to a drachm; its unpleasant flavour may be concealed by a small addition of mice. A mixture of valerian in proof spirit and in volatile spirit is ordered in the Lon-

don Pharmacopoeia. Cats are very fond of the smell of this root, and seem to be intoxicated by it.

VALISNERIA, in botany, a genus of the Acoraceae class of plants, with a monopetalous tripartite flower; its fruit is a long, cylindrical, and unilocular capsule, containing numerous oval seeds. There are two species.

VALVE, in hydraulics, pneumatics, &c., is a kind of lid or cover to a tube, vessel, or orifice, contrived to open one way; but which, the more force with which it presses the other way, the closer it shuts the aperture, like the clipper of a bellows; so that it either admits the entrance of a fluid into the tube, or vessel, and prevents its return; or per-
mits it to escape, and prevents its re-

entrance.

Valves are of great use in the air-pump, and other wind-machines; in which they are usually made of pieces of blister. In hydraulic

engine, as the, emboll or suckers of pumps, are mostly strong leather, of a round figure, and fitted to the aperture either by a bar of brass, or a piece of leather, or by a ring, or a bar, or pipes. Sometimes they are made of two round pieces of leather enclosed between two other pieces of brass; having divers fore and back, which are covered with another piece of brass, moveable upwards and downwards, on a kind of axis, which goes through the middle of them all. Sometimes they are made of brass, covered over with leather, and turned with a line spring, which gives way upon a force applied against it; but upon the re-

cessing of that, returns the valve over the aperture. See Pun, and Hydrostatics.

VALVE, in anatomy, a thin membrane applied on several cavities and vessels of the body, to afford a passage to certain humours in going one way, and prevent their reflux towards the place whence they came.

VAN, VANT, or VAUNT, a term derived from the French avant, or avant, signifying before, or foremost of any thing; thus we say, the van-guard of any army, &c.

VAN, in re-language, denotes the foremost division of any naval armament, or the part that usually leads the way to battle, or advances in the order of sailing.

VANDELLIA, a genus of plants of the class dicotyledon andorder angiosperm. The calyx is quadrid; the corolla rufous; the two exterior filaments proceed from the disc of the lip of the corolla; the anthers are connivent, i.e. connected; the capsule is monocolar and polyspermous. There are only two species known, the diffusus and pratensis.

VANE, in a ship, &c., a thin slip of some kind of matter, placed on high in the open air, and moving easily round on an axis or spindle, and veered down by the wind, to show its direction or course.

VANES, in mathematical or philosophical instruments, are sights made to slide and move upon cross-staves, fore-staves, quad-

rants, &c.

VANGNESIA, a genus of plants of the class and order perenandria monogynia. The calyx is five-toothed; corolla tube globular, stigma bilobate: fruit one-seeded: berry inferior, fleshy and juicy. There is one species, a tree of China.

VANILLA. See Epidendrum.

APOUR. See Evaulation, and Fluidity.
VARIABLE. In geometry and analysis, a term applied by mathematicians to such quantities as are considered in a variable or changeable state, either increasing or decreasing. Thus the abscissae and ordinates of an ellipse, or other curve line, are variable quantities; because they vary or change their magnitude together, the one at the same time with the other. But some quantities may be variable by themselves alone, or while those connected with them are constant; as the abscissae of a parallelogram, whose ordinates may be considered as all equal, and therefore constant. Also the diameter of a cylinder, and the perimeter of a conic section, are constant, while their abscissae are variable. Variable quantities are usually denoted by the last letters of the alphabet, $x, y, z, \ldots$; while the constant ones are denoted by the leading letters, $a, b, c, \&c.$ Some authors, instead of variable and constant quantities, use the terms fluent and stable quantities.

The indefinitely small quantity by which a variable quantity is continually increased or decreased in very small portions of time, is called the increment of the quantity, and is denoted by a line drawn through the equal letters in a, b, c, &c.

And the rate of its increase or decrease at any point, is called its fluxion; while the variable quantity itself is called the fluent. And the calculation of these, is the subject of the new method of differentials, or doctrine of fluxions.

VARIANCE, in law, signifies any alteration of a thing formerly laid in a plea; or where the declaration in a cause differs from the writ, or from the deed upon which it is grounded. 2 Lea, Abr. 669.

If there is a variance between the declaration and the writ, it is error, and the writ shall abate. And if there appears to be a material variance between the matter pleaded, and the manner of pleading it, this is not a good plea; for the manner and manner of pleading ought to agree in substance, or there will be no certainty in it. Cro. Jac. 479.

VARIATION, in geography and navigation, is the deviation of the magnetic needle from the true north point, towards either the east or west; or it is an arch of the horizon, intercepted between the meridian of the place of observation and the magnetic meridian. See MAGNETISM.

VARIATION, in astronomy. The variation of the moon, called by Galliard the refraction of her light, is the third inequality observed in the moon’s motion; which, by which, when out of the quadratures, her true place differs from her place in the equated line. See ASTRONOMY.

Newton makes the moon’s variation to arise partly from the form of her orbit, which is an ellipse; and partly from the inequality of the spaces which the moon describes in equal intervals, or the line drawn to the earth.

To find the greatest variation. Observe the moon’s longitude in the octants; and to the time of observation compute the moon’s place twice equated; then the difference between the computed and observed place, is the greatest correction.

Tycho makes the greatest variation 40' 20"; and Kepler makes it 51' 40". But Newton makes the greatest variation, at a mean distance between the sun and the earth, to be $35' 10''$; at the other distances, the greatest variation is $33' 19''$. The duplicate ratio of the times of the moon’s syzygial and apogee revolutions; and the triple ratio of the distance of the sun from the earth inversely. And therefore in the sun’s apogee, the greatest variation is $35' 19''$, and in his perigee $37' 11''$; provided that the eccentricity of the sun is to the transverse semidiameter of the orbit magna, as $16 \frac{2}{3}$ to 1000. Or, taking the mean motions of the moon from the sun, as they are stated in Dr. Halley’s tables, then the greatest variation at the mean distance of the earth from the sun will be $33' 7''$, in the apoapse of the sun $33' 27''$, and in his perigee $36' 51''$.

VARIATION of curvature, in geometry, is used for that inequality or change which takes place in the curvature of all curves except the circle, by which their curvature is more or less in different parts of them. And this variation constitutes the quality of the curvature at any point of a curve.

Sir Isaac Newton makes the index of the inequality, or variation of curvature, to be the ratio of the fluxion of the radius of curvature to the fluxion of the curve itself; and that Newton, in order to avoid the different notions, connected with the same terms, occasions to learners, has adopted the same denition; but he suggests, that this ratio gives rather the variation of the ray of curvature, and that it has been proper to have measured the variation of curvature rather by the ratio of the fluxion of the curve itself to the fluxion of the curve; so that, the curvature being inversely as the radius of curvature, and consequently its fluxion as the radius itself directly, and the square of the radius inversely, its variation would have been directly as the measure of it according to Newton’s definition, and inversely as the square of the radius of curvature.

According to this notion, it would have been measured by the angle of contact contained by the curve and circle of curvature, in the same manner as the curvature itself is measured by the angle of contact contained by the curve and tangent. The reason of this remark may appear from this example: The variation of curvature, according to this definition, is in the logarithmic spiral, the fluxion of the radius of curvature in this figure being always in the same ratio to the fluxion of the curve; and yet, while the spiral is produced, though its curvature decreases, it never vanishes; which must appear a strange paradox to those who do not attend to the import of Sir Isaac Newton’s definition.

The variation of curvature at any point of a conic section, is always as the tangent of the angle contained by the diameter that passes through the point of contact, and the perpendicular to the curve at the same point; or to the angle formed by the diameter of the section, and of the circle of curvature. Hence the variation of curvature vanishes at the extremities of either axis, and it is greatest when the acute angle, contained by the diameter passing through the point of contact and the tangent, is greatest.

When the conic section is a parabola, the variation is as the tangent of the angle, contained by the right line drawn from the point of contact to the focus, and the perpendicular to the curve. See CURVATURE.

From Sir Isaac Newton’s definition may be derived practical rules for the variation of curvature, as follows:

1. Find the radius of curvature, or rather its fluxion, then divide this fluxion by the fluxion of the curve, and the quotient will give the variation of curvature; exterminating the fluxions when necessary, by the equation of the curve, or perhaps by expressing the help of the tangent, or ordinate, or subnormal, &c.

2. Since $\frac{x}{y}$ or $\frac{1}{y}$ (putting $x = 1$) denotes the radius of curvature of any curve $s$, whose absciss is $x$, and ordinate $y$, if the fluxion of this is divided by $x$ and $y$ are exterminated, the general value of the variation will come out $-\frac{x^2}{y^2} + \frac{1}{y}$; then, substituting the values of $x, y, z$, (found from the curvature of the curve), into this quantity, it will give the variation sought.

Ev. Let the curve be the parabola, whose equation is $ax = y^2$. Here then $2by = ax = s$, and $y = \frac{s}{2b}$; hence $y = \frac{sa}{2b^2}$, and

\[ y = \frac{3a^2y}{2b^2} = \frac{3a^2}{2b^2} = \frac{3}{2b^2}. \]

Therefore

\[ \frac{3a^2}{2b^2} + \frac{1}{y} \left(1 + \frac{3}{2b^2}\right) = \frac{3a^2}{2b^2} + 3. \]

The variation sought.

VARIOLE, the small-pox, in medicine. See MEDICINE, and VACCINATION.

VARNISH, a thick, viscous, shining liquor, used by painters, gliders, and various other artificers, to give a gloss and lustre to their works; as also to defend them from the weather, dust, &c. See RESINS.

A coat of varnish ought to possess the following properties: 1. It should be extended or spread over the surface, without leaving pores or cavities, that it should not crack or scale, and that it should resist water. Resins are the only bodies that possess these properties, consequently they must form the basis of every varnish. For this purpose, they must be dissolved, as minutely divided as possible, and combined in such a manner, that the imperfections of those that might be disposed to scale, may be corrected by others.

Resins may be dissolved by three agents: 1. by fixed, or fat oil; 2. by volatile, or essential oil; 3. by spirit of wine. Accordingly we have three kinds of varnish; fat, volatile varnish, essential oil varnish, and spirit varnish.

The great agents are of such a nature as either to dry up and become hard, or to evaporate, and fly off, leaving the resin fixed behind.
VARNISH.

Varnish should be carefully kept from dust, and in a clean vessel; they should be laid as thin and even as possible, with a large flat brush, taking care to lay the strokes all one way. A warm room is best for varnishing in, as cold chills the varnish, and prevents it from lying even.

Varnishes are polished with pumice-stone and tripoli. The pumice-stone must be reduced to a very fine powder, and put upon a piece of soft moistened with water; with this the polished surface is to be rubbed equally and lightly. The tripoli must also be reduced to a fine powder, and put upon a clean woolen cloth moistened with olive-oil, with which the polishing is to be performed.

The varnish is then to be wiped with soft linen, and, when quite dry, cleaned with starch, or Spanish white, and rubbed with the palm of the hand, or with a linen cloth.

Fat oil varnish. Fixed, or fat oil, will not evaporate; nor will it become dry of itself. To make it dry, it must be boiled with alcohol, or turpentine. Litherer is generally used for this purpose. Oil so prepared is called drying-oil. To accelerate the drying of oil varnish, oil of turpentine is added.

Gum-copal, and amber, are the substances generally used in oil varnishes; the copal being whitest, is used for varnishing light; the amber for dark colours.

It is best to dissolve them before mixing with the oil; because, by this means, they are in less danger of being scratched, and at the same time the varnish is more beautiful. They should be melted in an iron pot over the fire; they are in a proper state for receiving the oil when they give no resistance to the iron spatula, and when they run from it drop by drop.

To make oil varnish, pour four, six, or eight ounces of drying-oil among sixteen ounces of melted copal, or amber, by little and little, constantly stirring the ingredients at the same time with the spatula. When the oil is well mixed with the copal or amber, take it off the fire; and when it is pretty cool, pour in sixteen ounces of the essence of Venice turpentine. After the varnish is made, it should be passed through a linen cloth.

Oil varnishes become thick by keeping; but when they are to be used, it is only necessary to pour in a little Venice-turpentine, and to put them a little on the fire. Less turpentine is necessary in summer than in winter; too much oil hinders the varnish from drying; but when too little is used, it cracks, and does not spread properly.

Black varnishes for coaches and ironwork. This varnish is composed of asphaltum, resin, and amber, melted separately, and afterwards mixed; the oil is then added, and afterwards the turpentine, as directed above. The usual proportions are, twelve ounces of amber, two of resin, two of asphaltum, six of oil, and twelve of turpentine.

A varnish for rendering silk water and air-tight. To render the linseed-oil drying, boil it with two ounces of sugar of lead, and three ounces of litharge, for every pint of oil, till the oil has dissolved them; then put a pound of birdline, and half a pint of the drying-oil, into a pot of iron or copper, holding about a gallon; and let it boil gently over a slow charcoal fire, till the birdline begins to crackle; then pour upon it two pints and a half of drying-oil, and boil it for about an hour longer, stirring it often with an iron or wooden spoon. When the varnish is no longer boiling, swell it much, the pot should be removed from the fire, and replaced when the varnish subsides. While it is boiling, it should be well examined, in order to determine whether it has boiled enough. For this purpose, take some of it upon the blade of a large knife, and after rubbing the blade of another knife upon it, separate the two knives, and when, on their separation, the varnish begins to form threads between the two knives, it has boiled enough, and should be removed from the fire. When it is almost cold, add about an equal quantity of spirit of turpentine; mix both well together, and let the mass rest till the next day; then, having warmed it a little, strain and bottle it. If it is too thick, add spirit of turpentine. This varnish should be laid upon the stuff when perfectly dry, in a lukewarm state; a thin coat of it upon one side, and, about twelve hours after, two other coats should be laid on, one on each side; and in 24 hours the silk may be used.

Mr. Blanchard’s varnish for air-balloons. Dissolve, or dissolve in oil varnishes; oil (carmichael) rubber, cut small, in five times its weight of spirit of turpentine, by keeping them some days together; then boil one ounce of this solution in eight ounces of drying linseed-oil for a few minutes, and strain it. Use it warm.

Essential oil varnish. The essential varnishes consist of a solution of resin in oil of turpentine, or other essential oil. This varnish being applied, the turpentine evaporates, leaving the resin behind. They are commonly used for pictures.

Spirit varnishes. When resins are dissolved in alcohol, commonly called spirit of wine, the varnish dries very speedily, but is subject to crack. This fault is corrected by adding a small quantity of oil of turpentine, which renders it brighter, and less brittle when dry.

To dissolve gum-copal in spirit of wine. Dissolve half an ounce of camphor in a pint of alcohol, or spirit of wine; put it into a circulating glass, and add four ounces of copal in small pieces; set it in a sand-heat, and regulate it so that the copal may be dissolved as they rise from the bottom; and continue the same heat till the solution is completed.

Camphor acts more powerfully upon copal than any other substance. If copal is finely powdered, and a small quantity of dry camphor rubbed with it in the mortar, the whole becomes in a few minutes a tough coherent mass. The process above described will dissolve more copal than the menstruum will retain when cold. The most economical method will therefore be, to set the vessel which contains the solution by for a few days; and when it is perfectly settled, pour off the clear varnish, and leave the residuum for a future operation.

This is a very bright solution of copal; it is an excellent varnish for pictures, and may perhaps be found to be an improvement in fine japanning; as the staves used in japanning those articles may be covered of this copal varnish entirely, and leave the copal pure and colourless upon the work.

A varnish for wagon-cots, cane-chairs, &c. Dissolve in a quart of spirit of wine, eight ounces of gum-sandarach, two ounces of seed-oil, or resin; then add six ounces of Venice turpentine. If the varnish is to produce a red colour, more of the lac and less of sandarach should be used, and a little dragon’s-blood should be added. This varnish is very strong.

A varnish for toilet-boxes, cases, fans, &c. Dissolve two ounces of gum-mastic, and eight ounces of gum-sandarach, in a quart of alcohol; then add four ounces of Venice-turpentine, and mix well; and hang them over a slow fire till they are dissolved; then add two ounces of turpentine.

Varnish for employing vermilion for painting engravings. Dissolve in a quart of alcohol six ounces of sandarach, three ounces of gum-lac, and four ounces of resin; afterwards add six ounces of the cheapest kind of turpentine; mix it with a proper quantity of vermilion when it is to be used.

A varnish for spirit of wine, one quart; put it in a wide-mouthed bottle; add to it eight ounces of seed-lac, that is large-grained, bright, and clear, free from dirt and stucks; let it stand two days, or longer, in a warm place, often shaking it. Strain it through a flannel into another bottle, and it is fit for use.

Shell-lac varnish. Take one quart of spirit of wine, eight ounces of the thinnest and most transparent shell-lac, which, if melted in the flame of a candle, will draw out in the longest and finest hair; mix and shake these together, and let them stand in a warm place for two days, and it is ready for use. This varnish is softer than that which is made from seed-lac, and therefore is not so useful; but may be mixed with it for varnishing wood, &c.

White varnish for clock-faces, &c. Take of spirit of wine (highly rectified) one pint, which divide into four parts; take five six one part with half an ounce of gum-mastic, in a phial; one part of spirit, and half an ounce of gum-sandarach, in another phial; one part of gum-lac, and half an ounce of the whitest parts of gum-benjamin. Then mix, and temper them to your mind. It would not be amiss to add a little bit of white resin, or clear Venice-turpentine, in the mustard-bottle, it will assist in giving a gloss. If your varnish proves too strong and thick, add spirit of wine only; if too hard, some dissolved mastic; if too soft, some sandarach or benjamin. No other rule can be given, unless the quality of the gums and the spirit could be ascertained. When you have brought it to a proper temper, warm the silvered plate before the fire, and with a flat camel’s-hair pencil, stroke it all over until no white streaks appear.

VARNISH, among medalists, signifies the colours antique medals have acquired in the earth.

The beauty which nature alone is able to give to medals, and art has never yet attained to the same extent, is derived from the value of the metal; that is, the colours, with which certain soils, in which they have a long time lain, tinge
VAU

the metals; some of which are blue, almost as beautiful as the turquoise; others with an inimitable vermillion colour; others with a certain shining polished brown, vastly finer than British lignum.

The most usual varnish is a beautiful green, which hangs to the finest strokes without effacing them, more accurately than the finest enamel does on metal. No metal but brass is susceptible of this; for the green rust that gathers on silver always spoils it, and it must be got off with vinegar or lemon-juice.

Falsifiers of metals have a false or modern varnish, which they use on their coppers, to give them the appearance, or air, of being antique. But this may be discovered by its softness, it being softer than the natural varnish, which is as hard as the metal itself. Some deposit their spurious metals in the earth for a considerable time, by which means they contract a sort of varnish, which may impose upon the less knowing; others use sal ammoniac, muriat of ammonia, and others burnt paper.

VARRONIA, a genus of plants of the class and order pantentia monogygia. The thistles, five-clad; drupes with a four-celled nut. There are nine species, shrubs of the West Indies.

VASSAL, in old-law books, denotes a tenant that held in fee of his lord, to whom he vowed fidelity and service.

VATERIA, a genus of the polyandria monogygia class of plants, the flower of which consists of five oval and patent petals; and its fruit is a turbinate, conicaceous, and unilocular capsule, containing a single oval seed.

There are one, a tree of Chine, which is known to contract a sort of varnish, which may impose upon the less knowing; others use sal ammoniac, muriat of ammonia, and others burnt paper.

VAULT, in architecture, an arched roof, so contrived that the stones which form it sustain each other. Vaults are, on many occasions, to be preferred to soffits or ceilings, as they give a greater height and elevations, and are besides more firm and durable.

Salsamius observes, that the antients had only three kinds of vaults. The first was the formix, made cradle-wise; the second a tabula, i.e. tortoise-wise, which the French call car de four, or oven-wise; and the third concha, or trumpet-wise. But the moderns have subdivided these three sorts into many more, to which they have given different names, according to their figures and uses; some of them are circular, and others elliptical.

Again, the sweeps of some are larger, others less, portions of a sphere. All such as are above hemispheres are called high, or surmounted vaults; and all that are less than hemispheres, are called low, or surused vaults, or testudines.

In some vaults the height is greater than the diameter; in others it is less; others again are quite flat, and only made with laurens; others like ovens, or in the form of a cul de four, &c. and others growing wider as they lengthen, like a trumpet.

VAULTS, master, were vaults that cover the principal parts of buildings, in contradistinction to the upper or subordinate vaults, which only cover some little part, as a passage or gate, &c.

VAULTS, double, is one that is built over another, to make the outer decoration range with the inner; or, to make the beauty and decoration of the inside consistent with that of the outside, leaves a space between the concavity of the one and the convexity of the other; instances of which we have in the dome of St. Peter’s at Rome, St. Paul’s at London, and in that of the Invalids at Paris.

Vaults with compartments, are such whose sweep, or inner face, is enriched with panells of sculpture, separated by platbands. These compartments, which are of different figures according to the vaults, and usually gilt on a white ground, are made with stone or brick walls, as in the church of St. Peter at Rome, or with plaster on timber vaults.

VAULTS, theory of. A seicircular arch or vault, standing on two piedrots, or imposts, and all the stones that compose them, being cut, and placed in such manner as that their joints or beds, being prolonged, do all meet in the centre of the vault; it is evident that all the stones must be in the form of wedges, i.e. must be wider and bigger at top; by the nature of which, if each one of them, and mutually oppose the effort of their weight, which determines them to fall. The stone in the middle of the vaults, which stands perpendicular to the horizon, and is called the key of the vault, is sustained on each side by two contiguous stones, just as by two inclined planes; and, consequently, the effort it makes to fall is not equal to its weight. But still that effort is the greater, as the inclined planes are less inclined; so that if they were infinitely little inclined, i.e. if they were perpendicular to the horizon as well as the key, it will tend to fall with its whole weight, and would actually fall but for the mortar. The second stone, which is on the right or left of the key-stone, is sustained by a third, which, by virtue of the figure of the vault, is necessarily more inclined to the second than the second is to the first; and consequently the second, in the effort it makes to fall, employs a less part of its weight than the first. For the same reason, the stones from the key-stone employ still a less and less part of their weight to the third, which, resting on a horizontal plane, employs no part of its weight, or, which is the same thing, makes no effort at all, as being entirely supported by the impost. Now, in vaults, a great point to be aimed at is, that all the vousoirs, or key-stones, make an equal effort towards falling. To effect this, it is visible, that as each (reckoning from the key to the impost) employs still a less and less part of its whole weight; the first, for instance, only employing one-half; the second, one third; the third, one-fourth, &c. there is no other way of making those different parts equal, but by a proportionate augmentation of the whole; i.e. the second stone must be heavier than the first, the third than the second, &c. to the last, which should be infinitely heavier.

M. De la Hire demonstrates what proportion is, in which the weight of the stones of a semicircular vault is to be increased in equilibrio, or to tend with equal forces to fall, which is the firmest disposition a vault can have. The architects before

had no certain rule to conduct themselves by, but did all at random. Beckett, in the treatise of the quadrature of the circle, from the key-stone to the impost, the extremity of each stone will take up so much the greater arch as it is farther from the key.

M. De la Hire’s rule is, to augment the weight of each stone that is at or the key-stone, as much as the tangent of the arch of the stone exceeds the tangent of the arch of half the key. Now the tangent of the last stone of necessity becomes infinite, and of consequence its weight should be so too; but, as infinity has no place in practice, the rule amounts to this, that the last stones should be loaded as much as possible, that they may the better resist the effort which the vault makes to separate them, which is called the shoot or drift of the vault. Mr. Parent has since determined the curve, or figure, which the extrados, or outside of a vault, whose intrados, or inside, is spherical, must have, that all the stones may be in equilibrio.

VAULT, key of, is a stone or brick in the middle of the vault, in form of a truncated cone, serving to bind or fasten all the rest.

VEIL, a veil, or mantilla, a sector of heretics who sprang up in Germany about the year 1590, and maintained that the body of Jesus Christ is ubiquie, everywhere, or, in every place, at the same time. However, they were not quite agreed among themselves; some holding, that the body of Jesus Christ, even during his mortal life, was everywhere; and others dating the ubiquity of his body from the time of his ascension.

VECTOR, in astronomy, a line supposed to be drawn from any planet moving round a centre, or the focus of an ellipse, to that centre or focus.

VEER, a sea-term variously used. Thus veering out a rope, denotes the letting it go by hand, or letting it run of itself. It is not used for letting out any running rope except the sheet.

VEER is also used in reference to the wind; for, when it changes often, they say it veers about.

VEGETATION. See Plants, physiological of.

VEIN. See Anatomy.

Vein, among miners, is that space which is bounded with wougs, and contains ore, spar, canck, clay, chert, croil, brownien, pitcher-chirt, ear, which the philosophers call the mother of metals, and sometimes soil of all colours. When it bears ore, it is called a quick vein; when no ore, a dead vein.

VELEZIA, a genus of the pantentia di- gynia class and order of plants. The calyx is five-clad; petals five; anthers 15, sessile, four-celled. There is one species, a tree of Chine, which is known to contract a sort of varnish, which may impose upon the less knowing; others use sal ammoniac, muriat of ammonia, and others burnt paper.

When the glue is thoroughly dry, it is taken out of the press, and finished; first with a little planer, then with scrapers, some of which resemble rasps, which take off the dents, &c., left by the planes.

After it has been sufficiently scraped, they polish it with the skin of a dogfish, wax, and a brush, orrather of share-grass, which is the last operation.

VENILE FACIAS, in law, a writ judicial, awarded to the sheriff to cause a jury of the neighborhood to appear, and to take to and bring to the court, or if the jury come not within the time of this writ, then there shall go a habeas corpus, and after a distress, till they appear. 2 Haw. 783.

Venile facies, is also the common process upon any presentment, being in nature of a summons for the party to appear; and this is a proper process to be first awarded upon an indictment for any crime under the degree of treason, or felony, or malum in se, in any case wherein other process is directed by statute. And if by the return to such writ of venire, it appears that the party has lands in the county, whereby he may be distrained upon, then a distress in infinitum shall be issued from time to time till he appears; but if the sheriff return that the party has no lands in his bailiwick, then upon his non-appearance, a writ of capias shall issue to take his body. 4 Black. 313.

VENTILAGO, a genus of the class and order of plants pentandria monogynia. The calyx is tubular; corolla, scales protecting the stamens, which are inserted in the calyx. There is one species, a shrub of the East Indies.

VENTILATOR, a machine by which the air of any close place, as an hospital, goose, ship, &c. may be changed for fresh air.

The moist qualities of bad air have been long known; and Dr. Hales and others have taken great pains to point out the mindless arising from foul air, and to prevent or remedy them. That philosopher proposed an easy and effectual one, by the use of his ventilators; the advantage of which is, was read before the Royal Society in May 1741. In mines, ventilators may guard against the suffocations, and other terrible accidents, arising from stopps. The air of goas has often proved infectious; and we had a fatal proof of this, by the accident that happened some years since at the Old Bailey sessions. After that ventilators were used in the prisons, which were worked by a small windmill, as that placed on the top of Newgate, and the prison became more healthy.

Dr. Hales further suggests, that ventilators might be of use in making salt; for which purpose there should be a stream of water to work them; or they might be worked by a windmill, and the brine should be in long narrow canals, covered with boards of canvas, a foot above the surface of the brine, to confine the stream of air, so as to make it act upon the surface of the brine, and carry off the water in vapours. Thus it might be reduced to a dry salt, with a saving of fuel, in winter and summer, or in rainy weather, or any state of the air whatever. Ventilators, in addition, might also serve for drying linen hung in low, long, narrow galleries, especially in damp or rainy weather, and also in drying woollen cloths after they are fulled or dyed; and in this case, the ventilators might be worked by the falling watermill. Ventilators might also be an useful appendage to mills and hemp-mills; and the same ventilator is farther a ventilation of warm dry air from the adjoining stove, with a cautious hand, might be of service to trees and plants in green-houses; where it is well known that air full of rancid vapours which perspire from the plants, is very unkindly to them, as well as the vapours from human bodies are to men; for fresh air is as necessary to the healthy state of vegetables, as of animals. Ventilators are also of excellent use for drying corn, hops, and malt. Gunpowder may be thoroughly dried, by blowing air up through it by means of ventilators; which is of great advantage to the strength of it. These ventilators, even the smaller ones, will also serve to purify most easily, and effectually, the bad air of a ship's well, before a person is sent down into it, by blowing air through a trunk reaching near the bottom of it. And in a current of air from a ventilator, the breath of a man, and all kinds, &c., be sweetened, &c., by passing a current of air through them, from bottom to top, which will carry the offensive particles along with it.

The method of drawing off air from ships by means of fire-pipes has been preferred to ventilators, was published by Sir Robert Moray, in the Philos. Trans., for 1605. These are metal pipes, about 24 inches in diameter, one of which reaches from the fire-place to the ship, and three others: branch go to other parts of the ship; the stove-hole and ash-hole being closed up, the fire is supplied with air through these pipes.

In the latter part of the year 1741, Mr. Trigland, military architect to the king of Sweden, informed the secretary to the Royal Society, that he laid in the preceding spring a machine for the use of ships of war, to draw out the foul air from under their decks, which consisted of 9172 cubic feet of air in an hour, or at the rate of 21722 tons in 24 hours. In 1742 he sent one of these to France, which was approved of by the Academy of Sciences at Paris, and the navy of France ordered to be furnished with the like ventilators.

There are various ways of ventilation, or changing the air of rooms. Mr. Tindal continued to admit fresh air into a room, by taking out the middle upper sash pane of glass, and fixing in its place a frame box, with a round hole in its middle, about six or seven inches diameter; in which hole are fixed, behind each other, a set of sails of very thin broad copper-plates, which spread over and cover the circular hole, to make the air which enters the room, and turning round these sails, to spread round in thin sheets sideways; and so it is inhaled by persons by blowing directly upon them, as it would be, if it was not hindered by the sails.

This method however is very uneasy, and disagreeable in good rooms; and therefore, instead of it, the late ingenious Mr. John Whitelith substituted another; which was, to make a small square or rectangular hole in the party-wall of the room, in the upper part near the ceiling, at a corner, the distant from the fire; and before it placed a
VEN

V E N

thin piece of metal or pasteboard, &c. attached to the wall in its lower part just below the hole, but declining from it upwards, so as to give the air, that enters by the hole, a direction upwards against the ceiling, along which it swims and inwards, and thence itself thence without blowing in a current against any person. This method is very useful to cure smoky chimneys, by thus admitting conveniently fresh air. A picture or painting was also attached before the hole prevents the sight of it when disfiguring the room. This, and many other methods of ventilating, he meant to have published, and was occupied upon, when death put an end to his useful labours. Those since have been published, viz. in 1792, Aby de Willan.

VENTRILLOQUISM, an art by which certain persons can so modify their voice, as to make it appear to the audience to proceed from any distance, and in any direction. Some faint traces of this art are to be found in the writings of the ancients; and it is the opinion of M. De la Chapelle, who in the year 1792 published an ingenious work on the subject, that all sweats of many of the ones were delivered by persons thus qualified, to serve the purposes of delusion. As the ancient ventriloquists, when exercising their art, seemed generally to speak with their own hands, a name by which they were doted was abundantly significant: but it is with no great propriety that modern performers are called ventriloquists, and their art ventriloquism, since they appear more frequently to talk with the pockets of their neighbors, or from the roof or distant corners of the room, than from their own mouths or their own bellies.

From Brodole, a learned critic of the sixteenth century, we have the following account of the feats of a capital ventriloquist and cheat, who was valet-de-chambre to Francis the First. The fellow, whose name was Louis Brabant, had fallen deeply in love with a young, handsome, and rich heiress; but was rejected by the parents as an unsuitable match for their daughter, on account of the lowness of his circumstances. The young lady’s father dying, he set out to win her, totally ignorant of her singular talent. Suddenly, on his first appearance in open day, in her own house, and in the presence of several persons who were with her, she heard herself acceded, in a voice perfectly resembling that of her dead husband, and which seemed to proceed from above, exclaiming, “Give my daughter in marriage to Louis Brabant; he is a man of great fortune, and of an excellent character. I now endure the insupportable torments of purgatory, for having refused her to him. If you obey this admonition, I shall soon be delivered from this place of torment. You will at the same time provide a worthy husband for your daughter, and procure everlasting reposé to the soul of your poor husband.”

The widow could not for a moment resist this dreadful summons, which had not the most distant appearance of proceeding from Louis Brabant, whose countenance exhibited no visible change, and whose lips were close and motionless, during the delivery of it. Accordingly, she consented immediately to receive him for her son-in-law. Louis’s finances, however, were in a very low situation; and the formalities attending the marriage-contract rendered it necessary for him to exhibit some show of riches, and not to give the ghost the lie. Accordingly, he worked upon a fresh subject, one Cornu, an old and rich banker at Lyons; who had accumulated immense wealth by usury and extortion, and was known to be haunted by remorse of conscience in the manner in which he had acquired it.

Having contracted an intimate acquaintance with this man, he, one day while they were sitting together in the insurer’s little back parlour, artfully put off the conversation to religious subjects, on demons and spectres, the pains of purgatory, and the torments of hell. During an interval of silence between them, a voice was heard, which to the astonished banker seemed to be that of his deceased father, complaining, as in the former case, of his dreadful situation in purgatory, and calling upon him to deliver him instantly thence, by putting into the hands of Louis Brabant, then with him, a large sum for the redemption of Christians then in slavery with the Turks; threatening him at the same time with eternal damnation if he did not take this method to expiate like-wise his own sins. The banker naturally supposed that Louis Brabant affected a due degree of astonishment on the occasion; and further promoted the deception, by acknowledging his having devoted himself to the prosecution of the charitable design imputed to him by the ghost. An old usher is naturally suspicious. Accordingly the wary banker made a second appointment with the ghost’s delegate for the next day; and, to render any design of imposing upon him utterly abortive, took him into the open fields, where not a house, or a tree, or even a bush, or a pit, was in sight, capable of screening any supposed confederate. This extraordinary caution excited the ventriloquist to exert all the powers of his art. Wherever the banker conducted him, at every step his ears were saluted on all sides with the complaints and groans not only of his father, but of all his deceased relatives, praying for the love of God, that in the name of every saint in the calendar, to have mercy on his own soul and theirs, by effectually seconding with his purse the intentions of his worthy companion. Cornu complained the voice of heaven had accordingly carried his guest home with him, and paid him down 10,000 crowns: with which the honest ventriloquist returned to Paris, and married his mistress. The catastrophe was fatal. The secret was afterwards discovered, and reached the userer’s ears; who was so much affected by the loss of his money, and the mortifying railleys of his neighbours, that he took to his bed and died.

This trick of Louis Brabant is even exceeded by an innocent piece of waggery played off not forty years ago by another French ventriloquist on a whole community. We have the story from M. De la Chapelle, who informs us, that M. St. Gill, the ventriloquist, and his intimate friend, returning home from a place whither his business had carried him, sought for shelter from an approaching thunder-storm in a neighbouring conveny. Finding the whole community in mourning, he enquired the cause, and was told that one of their body had died lately, who was the ornament and delight of the whole society. To pass away the time, he walked into the church, attended a service in a very solemn manner, and made a most lugubrious address to the corpse of his deceased brother, and spoke feelingly of the scanty honours they had bestowed on his memory. Suddenly a voice was heard, appr. room, proceeding from the pulpit, lamenting the situation of the deject in purgatory, and reproaching the brotherhood with their lukewarm and want of zeal on his own account. The friars, as soon as the astonishment gave them power to speak, consulted together, and agreed to acquit the rest of the community with this singular event, so interesting to the whole society. M. St. Gill, who wished to carry on the joke still farther, dissuaded them from taking this step: telling them that they would be treated by their absent brethren as a set of fools and visionaries. He recommended to them, however, the immediately calling of the whole community into the church, where the ghost of their departed brother might probably reiterate his complaints. Accordingly all the friars, novices, lay-brothers, and even the domestics of the community were immediately invited to a meeting collected together. In a short time the voice from the roof renewed its lamentation and reproaches, and the whole convent fell on their faces, and vowed a solemn reparation. As a further step, they chanted a De profundis in a full choir, during the intervals of which the ghost occasionally expressed the comfort he received from their pious exercises and ejaculations on his behalf. When all was over, some of them entered into a solemn conversation with M. St. Gill; and on the strength of what had just passed, sagaciously inveighed against the absurd incredulity of modern sceptics and pretended philosophers, on the article of ghosts and apparitions. M. St. Gill thought it now high time to disabuse the good fathers. This purpose, however, he found it extremely difficult to effect, till he had prevailed upon them to return with him into the church, and there be witnesses of the manner in which he had conducted this ludicrous deception.

A ventriloquist, who performed feats somewhat similar to these, made his appearance in Edinburgh, the capital of Great Britain, a few years ago. He imitated successfully the voice of a squeaking child, and made it appear to proceed from whatever place he chose; from the pockets of the company; from a wooden doll, with which he held many spirited conversations; from beneath a hat or a wine-glass, and out of any person’s foot or hand. When the voice seemed to come from beneath a glass or hat, it was attributed on a lie, as sounds confined always are; and what evinced his dexterity was, that when the glass was raised from the table during the time of his speaking, the words or syllables uttered afterwards were on a higher key: in consequence, one would have thought, of the air being readmitted to the speaker. This part of the experiment failed, however, when the management of the glass was at a distance committed to any of the company; last of all, the room was not well illuminated, we are inclined to attribute this failure to the ventriloquist not being able to perceive at what precise instant of time the glass was removed from the table.

Vol. II.
The same artist imitated the tones of a scold- ing old woman, disturbed at unreasonable hours by a person denominating admission into her house. We have heard that, when in Edinburgh, the same practicioner astonished a number of persons in the Fishmarket, by making a speech to speak, and give the lie to his vender, who affirmed that it was fresh, and caught in the morning.

The editor of this dictionary heard some years ago, in Portugal, a ventriloquist who was at least equal to any of those above-men- tioned. Indeed, he could scarcely have be- lieved the fact from any authority, had he not been himself an ear-witness. The man held conversation with the figure of a child, which he carried under his cloak, with per- sons apparently out of the room, in the street, and even on the roof of the house. The voices were all varied according to the character of the person with whom he affect- ed to converse, and it was impossible not to believe that they proceeded from the quarter where he pretended they were stationed.

We have never, we confess, found a satis- factory explanation of this phenomenon. The most which are that which refers it to a cer- tain delicacy of ear, proper to the performer. Such an ear, it is observed, perceives every difference which change of place produces in the same sound; and if a person possessed of such an ear has sufficient command over his organs of speech, he can produce by them a sound in all respects similar to another proceeding from any distant object, to the audience the sound which he utters must appear to pro- ceed from that object. If this is the true theory of ventriloquism, it does not seem to be possible for the most expert ven- triloquist to speak in his usual tones of con- versation, and at the same time make the voice appear to come from a distance; for these tones must be supposed familiar to his audience, and to be in their minds associated with the ideas of his figure, place, and distance. There can, however, be no doubt, that if, by a peculiar modification of the organs of speech, a sound of any kind can be produced, which in faintness, tone, body, and in short every other sensible quality, perfectly resembles a sound delivered from the roof of an elevated house, the ear will naturally, with- out examination, refer to that situation and distance; the sound which the person hears being only a sign, which he has from his in- fancy been constantly accustomed, by expe- rience, to associate with the idea of a person speaking from a house-top. If, however, this theory is true, how comes it that ven- triloquism is not more frequently and suc- cessfully practised? The man whom the editor saw in Portugal, was apparently an ignorant and illiterate person, and could not, or would not, give any account of the principles of his art.

VENUE, in law, the neighbourhood whence justice are to be summoned for trial of causes. In local actions, as of trespass and ejectment, the venue is to be from the neighbourhood of the place, where the lands in question lie; and in all real actions, the venue must be laid in the county where the thing in question is brought. In all cases, law, and even cases, will, if any, be tried in the district where the county, court will direct a change of the venue, and oblige the plaintiff to declare in the pro- per county; and the court will sometimes, if the business be of a public nature, (especially of that which is laid against limited kind.) upon a suggestion duly supported, that a fair and impartial trial cannot be had therein. 3 Black, 394.

With respect to criminal cases, it is ordin- ated by stat. 21 Jac. 1. c. 7, that all informa- tions on penal statutes, shall be laid in the counties where the offences were committed. 

VENUS, in astronomy, one of the inferior planets, revolving round the sun in an orbit between that of Mercury and the Earth. See Astronomy.

VENUS, in zoology, a genus of insects be- longing to the order of vermes testacea. This animal is a two-legs; the shell is bivalve; the wings with three teeth near each other, one placed longitudinally and bent inwards. There are a great many species, of which the most remarkable is the mercenaria, or commercial, with a long, thick, weighty shell, covered with a brownish, or olive-brown substance, with slightly striated transversely: circumference above 11 inches. These are called in North America clams; they differ from other spe- cies only in having a purple tinge within. Wampum, or Indian money, is made of them.

VENUS's fly-trap. See Dionaea Mus- cipula.

VEPRECULE, diminutive from verres, "a briar or bramble," the name of the 31st order in Linneus's Fragments of a Natural Method. See Botany. 

VERATRUM, a genus of plants of the class polygamus, and order monocot; and in the natural system arranged under the 23th order, lridaceae. The corolla is rotated, and rather unequal; the capsule is mono- locular and bivalved. There are 19 species, five of which belong to the countries of Britain:

1. The thapsus, or great mullein, which has a stem single, simple, crowded with leaves, about six feet high; leaves large, broad, white, woolly on both sides, sessile, de- current; flowers terminal, in a long spike, yellow,去看pair of two or four, naked or very thinly arilled; stamens two or four. There are 23 species, only one of which is a native of Britain; the officinalis, or common verbain, which grows on the road-sides near towns and villages. The leaves have many jagged edges, the blossoms are pale blue. It manifests a slight de- gree of astrigency, and was formerly much in use as a diuretic, but is now dis- regarded.

2. The nigraum, or black mullein, having a stem set with leaves that are beautifully branched; the blossom a yellow with purple tips. It is a beautiful plant, and the flowers are grateful to bees. Swine eat it; sheep are not fond of it; cows, horses, and goats, refuse it. The other British species are the yellow, lychnitis, blattana, and virginiana.

VERBENA, a genus of plants of the class diandra, and order monogynia; and in the natural system arranged under the 40th order, personate. The corolla is funnel- shaped; calyx one of the teeth truncate; seeds two or four, naked or very thinly arilled; stem two or four. There are 23 species, only one of which is a native of Britain; the officinalis, or common verbain, which grows on the road-sides near towns and villages. The leaves have many jagged edges, the blossoms are pale blue. It manifests a slight de- gree of astrigency, and was formerly much in use as a diuretic, but is now dis- regarded.

Air Miller says, that it is never found above a quarter of a mile from a house; whence the common people in England call it 'simple's joy,' because, wherever it is found, it is a certain sign of a house being near. Swine eat it; cows, horses, and goats, re- fuse it.

VERBESINA, a genus of the syngeneia
polygamy superfluous class of plants, with a radiated flower, made up of hemipatrid tulipose ones on the disc, and a few imitative ones on the verge; the seeds are angulated, and contained in the cup. There are eleven species.

VERDEGRISE, or VERDEGRIS. See COPPER.

Verdegris is an acetat of copper, useful in the arts as a pigment. The principles on which it is formed are these:

Acetic acid attacks copper very slowly in open vessels, converts it into an oxide, and dissolves it; but in close vessels no action takes place. This acid readily combines with the oxide of copper, and forms with it an acetat. This salt was known to the ancients, and various ways of preparing it are described by Pliny. It is usually obtained by exposing plates of copper to the action of vinegar, till they are converted to a bluish-green powder, and then dissolving this powder in acetic acid, and crystallizing it.

Acetat of copper crystallizes in four-sided truncated pyramids. It has a beautiful bluish-green colour. Its specific gravity is 1.779. Its taste is disagreeably metallic, and, like all the compounds into which copper enters, it is poisonous. It is very soluble in water; alcohol likewise dissolves it. When exposed to the air, it effloresces. By distillation it gives out acetic acid. Proust first remarked that acetic acid and acetic acid form the same salt with copper; and hence concluded that there is no difference between the two acids. When sulphureted hydrogen gas is made to pass through a solution of this salt in water, the copper is desvoltized, and precipitates in the state of a blue sulphuret, and there remains behind an acid which possesses the properties of the acetic.

According to Proust, the acetat of copper is composed of:

| 61 acid and water | 39 oxide | 100 |

When the verdigris of commerce is put into water, 0.36 parts of it are dissolved, and there remain 0.44 parts in the state of a fine green powder, which remains long suspended in the solution. Mr. Proust has ascertained that this powder is a subacetat of copper. It is decomposed by sulphuric acid, by potass, and by distillation. According to the analysis of Proust, it is composed of:

| 37 acid and water | 63 oxide | 100 |

Thus it appears from the experiments of this philosopher, that the verdigris of commerce is composed of two different acetats of copper; the one soluble in water, the other insoluble. It is much used as a paint; and crystallized acetat of copper is a frequent ingredient in dying compounds. Verdegris is formed in great quantities at Montpelier. A particular account of the processes followed in that place has been published by Mr. Chaptal.

VERDEROR, a judicial officer of the king's forest, chosen by the king's writ in the full county-court of the same shire, within the forest where he dwells; he is sworn to maintain the assizes of the forest, and to view, receive and enroll the attachments and presents, of all manner of trespasses of vert and venison in the forest.

VERDICT, the answer of a jury, made upon any cause, civil or criminal, committed by the court to their examination, and this is timid, general or special.

A general verdict is that which is given of brought into the court in like general terms to the general issue; as in an action of assize, the defendant pleads no wrong, no dissent; then the issue is general, whether the fact is wrong or not; which being committed to the jury, they upon consideration of the evidence come in and say, either for the plaintiff, that it is a wrong and dissent; or for the defendant, that it is no wrong, no dissent.

A special verdict, is when they say at large, that such a thing and such a thing they find to be true by the present or tenant, so declaring the course of the fact, as in their opinion it is proved; and as to the law upon the fact, they pray the judgment of the court; and this special verdict, if it contains any show of declaration of the cause from the beginning to the end, is also called a verdict at large. Co. Lit. 128.

A special verdict is usually found where there is any difficulty or doubt respecting the law, when the jury state the facts as proved, and pray the advice of the court thereon. A less expensive, and more speedy mode however, is to find a verdict generally for the plaintiff, subject, nevertheless, to the opinion of the judge, or the court above, on a special case drawn up and settled by counsel on both sides.

VERGE signifies the compass of the king's court, which bounds the jurisdiction of the lord steward of the household, and which is thought to have been 12 miles round.

The term verge is also used for a stick or rod, whereby one is admitted tenant to a copyhold estate, by holding it in his hand, and swearing fealty to the lord of the manor.

VERGES, certain officers of the courts kings'-bench and common pleas, whose business it is to carry white wands before the judges.

There are also vergers of cathedrals, who carry a rod tipped with silver before the bishop, dean, &c.

VERJUICE, a liquor obtained from grapes or apples, unit for wine or cider; or from sweet ones, whilst yet acid and unripe. Its chief use is in sauces, ragouts, &c. though it is also an ingredient in some medicinal compositions, and is used by the wax-chandlers to purify their wax.

VERMELS, the sixth class of animals in the Linnaean system, comprehending five orders. See NATURAL HISTORY, and ZOOLOGY.

VERNIER SCALE, a scale excellently adapted for the gradation of mathematical instruments, thus called from the inventor Peter Vernier, a person of distinction in the French Coupé. Vernier's method is derived from the following principles: If two equal right lines, or circular arcs, A, B, are so divided, that the number of equal divisions in B is one less than the number of equal divisions of A, then will the excess of one division of B above one division of A, be compounded of the ratios of one of A to B, and of one of B to A.

For, let A contain 11 parts, then one of A to B is as 1 to 11, or 1/11. Let B contain 10 parts, then one of B to B is as 1 to 10, or 1/10. Now

\[ \frac{1}{11} \times \frac{1}{10} = \frac{1}{110} \]

Or if B contains \( n \) parts, A contains \( n + 1 \) parts; then \( \frac{1}{n} \) is one part of B, and

\[ \frac{n + 1}{n} = \frac{1}{A} \]

is one part of A. And

\[ \frac{n + 1}{n} = \frac{1}{A} = \frac{1}{n + 1} \]

or

\[ \frac{1}{n + 1} = \frac{1}{n} \]

The most commodious divisions, and their aliquot parts, into which the degrees on the circular limb of an instrument may be supposed to be divided, depend on the radius of that instrument.

Let R be the radius of a circle in inches; and a degree to be divided into \( n \) parts, each being \( \frac{1}{n} \)th part of an inch.

\[ \text{Then } 360^\circ = \frac{360}{n} \times 2 \pi \text{ to } \frac{\pi}{n} \times 2 \pi \]

\[ \text{Then } 360^\circ = \frac{360}{n} \times 2 \pi \text{ to } \frac{\pi}{n} \times 2 \pi \]

\[ \text{Or, } 0.01745329 \times R \text{ is the length of one degree in inches.} \]

\[ \text{Or, } 0.01745329 \times R \times p \text{ is the length of } \frac{1}{p} \text{th part of an inch.} \]

But as every degree contains \( n \) times such parts, therefore \( \text{if } 0.01745329 \times R \times p \), the most commodious perceptible division is \( 1 \) of \( \frac{1}{10} \) of an inch.

Example. Suppose an instrument of 30 inches radius, into how many convenient parts may each degree be divided? how many of these parts are to go to the breadth of the vernier, and to what parts of a degree may an observation be made by that instrument?

Now, 0.01745329 \( \times \) R \( = \) 0.2536 inches, the length of each degree; and \( p \) is supposed about \( \frac{1}{8} \) of an inch for one division; then 0.2536 \( \times \) \( \frac{1}{8} \) = 0.0318 shows the number of such parts in a degree. But as this number must be an integer, let it be 4, each being \( \frac{1}{4} \); and let the breadth of the vernier contain \( 11 \) of those parts, or \( \frac{1}{4} \), and he divided into 50 parts.

Here \( n = \frac{1}{4} \); \( m = \frac{1}{30} \); then \( \frac{1}{4} \times \frac{1}{30} = \frac{1}{120} \) of a degree, or \( 0.30 \), which is the least part of a degree that instrument can show.

If \( n = \frac{1}{4} \); \( m = \frac{1}{36} \); then \( \frac{1}{4} \times \frac{1}{36} = \frac{1}{60} \) of a minute, or \( 20' \).

\[ \text{The following table, taken as examples in the instruments commonly made from 5 inches to 8 feet radius, shows the divisions of the inch to the nearest tenths of inches, so as to be an aliquot of 60's, and what parts of a degree may be estimated by the vernier, it being divided into such equal parts, and containing such degrees as their columns show.} \]

\[ \text{Columns} \]

\[ \text{Columns} \]

\[ \text{Columns} \]
VERVAIN. See Verbesa.

VESICA, in anatomy, a bladder; a membranous or spongy part, in which any humour is contained.

VESICATORY, an external medicine, serving to raise a blister; whence it is also itself, though improperly, called a blister.

VESPA, a genus of insects of the order Hymenoptera. The generic character is, mouth with jaws, without proboscis; upper wings plicate; sting concealed; eyes lunetted; body smooth.

The genus Vespina is of great extent, 140 species; and is remarkable, like that of apis or bee, for the singular dexterity with which it constructs its habitation, which in many species is of considerable size. The common wasp, or vespa, is known to every one. The nest of this species is a highly curious structure, and is prepared beneath the surface of some dry bank, or other convenient situation. Its shape is that of an upright oval, often measuring ten or twelve inches at least in diameter; it consists of several horizontal stages or stories of hexagonal cells, the interstices of each story being connected at intervals by upright pillars; and the exterior surface of the pillars is very much like their upper parts, disposed over each other in such a manner as to secure the interior cavity from the effects of cold and moisture; the whole nest, comprising both walls and cells, is composed of a substance very much resembling the coarser kinds of whitish-brown paper, and consists of the fibres of various dry vegetable substances, agglutinated by a tenacious fluid discharged from the mouths of the insects during their operations. The female wasps deposit their eggs in the cells, one in each cell appropriated for that purpose; from these are hatched the larve or maggots, which, in resemblance to those of bees, they are led by the labouring wasps with a coarse kind of honey, and when arrived at their full size, close up their respective cells with a fine tissue of silken filaments, and, after a short period, emerge in their complete or perfect form. The male insects, resembling the male bee, is destitute of a sting. The society or swarm of the common wasp, consists of a vast number of neutral or labouring insects, with a small number of males, and still fewer females. They do not, like the bees, prepare and lay up a store of honey for winter use; but the few which survive the season of their birth, remain torpid during the colder months. Wasps in general are both carnivorous and frugivorous.

The hornet, vespa crabro of Linnaus, is a species of a far more formidable nature than the common wasp, and is of considerably larger size, its body is a tawny yellow with a ferruginous and black bars and variegations. The nest of this species is generally built in the cavity of some decayed tree, or immediately beneath its roots; and not unfrequently in timber-yards and other similar situations. It is of smaller size than that of the wasp, and of a somewhat globular form, with an opening beneath; the exterior shell consisting of more or less layers of the same strong paper-like substance as that prepared by the wasp; the cells are also of a similar nature, but much fewer in number, and less elegantly composed. The hornet, like the wasp, is extremely voracious, and preys on almost any kind of fresh animal substances which it can obtain, as well as honey, fruit, &c. &c. Its sting is greatly to be dreaded, and is often productive of very serious consequences.

A highly elegant wood is sometimes seen during the summer season, attached or hanging by its base to some straw or other projecting substance, from the upper part of unfrequented buildings or out-houses. It does not reach much the size of an egg, but is of a more globular form, and consists of several concentric shells, with considerable intervals between each, the interior alone being fresh and fringed with a small round orifice; the rest is only about two-thirds from the base of the nest. In the centre of the complete or entire bell, is situated the congeries of cells, built round a small central pillar attached to the base: the cells are not so much divided, and their orifices look downwards. See Plate Nat. Hist. fig. 417.

VESPERTILIO, bat, a genus of mammals, of the order Primates. The generic character is, size of the ear-pointed, approximately; hands palmated, with a membrane surrounding the body, and giving the animal the power of flight.

The formation of these animals cannot be contemplated without admiration; the bones of the extremities being continued into long and thin processes, connected by a most delicately formed membrane or skin, capable, from its thinness, of being contracted at pleasure, as into wrinkles, so as to lie in a small space when the animal is at rest, and to be stretched to a very wide extent for occasional flight.

Some speculative philosophers, not aware of the anatomical impossibility of success, attempt, by means of light machinery, to exercise the power of flight, he could not hit on a more plausible idea than that of copying the structure described, and their orifices look downwards. See Plate Nat. Hist. fig. 417.

VESPERTILIO, bat, a genus of mammals, of the order Primates. The generic character is, size of the ear-pointed, approximately; hands palmated, with a membrane surrounding the body, and giving the animal the power of flight.

1. Vespertilio murinus, the common murinus, is about two inches and a half, if measured from the tip of the tail; and the extent of the wings, when fully expanded, is about nine inches. It is of a mouse-colour, tinged with reddish; the wings and ears black; these latter are small and rounded.

2. Vespertilio auritus, or long-eared bat. This species, in its general appearance, is nearly similar to the former, though rather smaller; and the fur less of the reddish tinge; but what immediately distinguishes it as a species, is the very long ear-point of the hind, which is more than an inch long, and of a very considerable width; they are slightly rounded at the tips, and are furnished internally, as in most others of this genus, with a kind of secondary auricle or internal ear, so placed as to serve by way of a valve or guard to the auditory passage. Linnaus, even in the twelfth edition of the Systema Naturalis, seems to entertain a doubt whether this species is at all distinct from the former, or merely a sexual difference.

This and the former are the two most common species in this country; and are those which we so often see flitting about in the
It is also equally evident, that the fabulous
haunts of the antelopes must have originated
from a similar source: the larger bats of
India and Africa, by a little poetical exaggera-
tion of their manners, answering extremely
well to the general description of those mon-
sters.

3. Vespertilio noctula, the noctule bat, is
considerably larger than the former; its ex-
tended wings measuring from 14 to 15 inches;
the length from the nose to the tip of the tail
about four inches and a half. The nose is
slightly bilobated; the ears small and round-
down; the body is bluff; the shoulders very
thick and muscular; the fur very soft and glossy,
and of a bright chestnut-colour. This is an
inhabitant of Britain and of France, but seems
not to have been part-

4. Vespertilio ferrum equi,
the horse-shoe bat, with
a horse-shoe membrane
at the tip of the nose;
ears large, broad at the
base, and sharply-pointed, inclining backward;
no small or internal ear; colour of the
upper part of the body deep-cinereous; of
the lower, whitish. There is said to be
a greater and smaller variety; perhaps
the male and female. The greater is above
three inches and a half long from the nose to the tip
of the tail; the extent of wing is about 15
inches. Native of Guiana.

5. Vespertilio auripendulins,
slouch-eared bat, with
tail large, included in
the membrane, and terminated with a hook;
projecting above the chestnut, lighter on the
belly, and cinereous on the sides; length
three inches and a half, which gives the extent of wing 15
inches. Native of Guiana.

6. Vespertilio leporinus,
Peruvian bat. Linnaeus,
Mr. Pennant well observes,
carried away by the love of system, placed
this species as a third of the family Vespertilinae in the Systema
Nature, under a distinct genus, by the
name of noctula; stationing it at a great distance
from the rest of the bats, in the order gilies,
next to the squirls. This he did merely
on account of its having only two cutting-teeth
in each jaw. But succeeding observations
have conspired to prove that the number and
disposition of the teeth differ greatly in the
different species of the bats; so that if a too
rigid regulation was paid to this particular,
several distinct genera might be instituted in
stead of one; but the general characters of
the bats are so striking as to render this per-
fecfly unnecessary.

The Peruvian bat has a head something like
a pig-dog; the ears large and straight,
sharp at the ends, and pointing forwards;
two canine teeth, and two small cutting teeth be-
tween, in each jaw; tail enclosed in the
membrane while it is flying; hind leg, and
is also supported by two long carinlges
involved in the membrane; colour
of the fur iron-grey; body equal in size to a
flighting rat; extent of wing two feet five
inches. Mr. Pennant observes, that Mr.
Schréder’s figure of this species is erroneously
coloured, being represented covered with
brown. In an extraordinary con-
form, according to Seba, takes place in
the legs of this bat; the tibia and fibula being
placed separately from each other, and each
inserted by a joint and tendon. These, however,
seem to be nothing more
than the two carinlges
mentioned by Mr. Pennant.

The remaining species (except the last) are
distinguished by having no tails.

7. Vespertilio nasutus, great woolen bat,
with a very long, straight, and strong nose,
slipping down at the end; ears long, erect,
dilated towards the bottom, rounded at the end;
colour of the upper part a reddish
chestnut; sides of a clear yellow; remainder of
a dirty white; length five inches and
eight lines; extent of wings two feet.

This species is described in the supple-
menal volume of the count de Buffon’s Natural
History. It is a native of Guiana, where it
is chiefly seen on palm trees. The extent of wings is about two feet
or more; and from the nose to the
rump seven inches and a half. It has
a long nose; large teeth; long, broad, and
upright ears; and at the end of the nose
is an upright, long, conical membrane, bending
at the end. Hair on the body cinereous,
and pretty long; wings full of ruffled fibres; the
membrane extends from hind leg to hind leg.

There is no tail; but three tendons run from
the rump to the edge of the membrane.

Mr. Buffon supposes this to be the
vampire; but if the accounts of that animal’s
extraordinary faculty may be depended upon,
we are still uncertain as to the species; Piso
may be the correct name, who gives the
particular description of the animal; and
indeed, it is most probable that the faculty
which gave rise to the name is by no means
confined to a single species, but may be pro-
cumbent in some of our southern
climates. See Plate Nat. Hist. fig. 416.

9. Vespertilio vampyrus, vampire bat. Of
this tremendous animal there are some vari-
eties in point of size and colour; or perhaps
they may really be distinct races or species,
thought nearly allied. The largest, or
the great Terinate bat, is, in general, about a foot
long; with an extent of wings about four feet;
but sometimes it is found far larger, and it
has been said that specimens have been seen
of six feet in extent. The general colour of
the body is a deep reddish brown; brighter
on the upper part of the neck and shoulders,
as well as on the under parts of the body.
The nose is large and sharp; there are four cutting-teeth
above and below, and the canine teeth are
large and strong; the tongue is pointed,
and terminated by sharp prickles; the ears are
naked, black, and large, and are of a pointed
form. The wings are black, or the colour
of those of the common bat. The
membrane is divided behind, quite to the
rump, there being no tail; the single claw
of
the wings is large and strong, and those on the feet extremely so, as well as much curved. This is the bat to which Linnaeus applied the title of vampire, on the supposition of its being the species of which so many extraordinary accounts have been given relative to its power of sucking the blood both of men and cattle. This it is supposed to perform by inserting its acutated tongue into the vein of a sleeping person, in so peculiar a manner as not to excite pain, fanning at the same time the air with its wings, by which means the sleep rendered still more profound. This is what appears at first so extraordinary as to justify a degree of scepticism as to the fact: it is, however, so solennely related, and seemingly so well authenticated, as to enforce belief. Mr. Comhounne assures us, that the large bats have, in certain parts of America, destroyed, by this means, all the great cattle introduced there by the missionaries. It is affirmed by Bontius, as well as Niederoff, that the bats of Java attack those who sleep by day, and whenever they can gain access; and Gumilla, who mentions a greater and lesser kind, found on the banks of the Orinoco, declares them to be equally greedy after human blood. Persons who had, in consequence, been near passing from a sound sleep into eternity. It is, therefore, very unsafe to sleep with open windows, or in the open air, in those regions.

P. Martyr, who wrote soon after the conquest of South America, says, that in the islandus of Darien, there are bats which suck the blood of men and cattle, when asleep, to such a degree as to awaken, and even kill them.

An instance is also related in Colonel Stedman's Travels in Surinam, as having happened to himself, which puts the matter beyond a doubt.

Lastly, though it seems to have escaped the attention of modern naturalists, the same faculty has been, in time out of mind, attributed to the common European bats, which are said to bite sleeping persons, and to suck the blood with the greatest avidity. This is mentioned by Aldrovandus, and is a generally-received opinion; observing, at the same time, that their attacks are infinitely inferior to the dangerous ones of the large exotic bats in India and America.

It remains to explain the reason of the term vampire, by which the above large species has been distinguished.

A vampire is an imaginary monster, supposed to suck the blood of sleeping persons. It also alludes to one of the most absurd superstitions that ever entered into the human mind. About the year 1732, an idea arose among the vulgar in some parts of Poland and Hungary, that certain bodies when interred, became possessed of the power of absorbing blood from those who were so unfortunate as to pass over or stand near their graves; it was generally supposed necessary to disinter such bodies and wound them with a sword, by which means this pernicious power was supposed to be put to a stop, and the blood they had unjustly gained was released. Although it is very unlikely to appear, it is yet more astounding that a great many treaties were written on the subject, and that some considerable time elapsed before the superstition was completely destroyed.

VESTALS, vestesides, among the ancient Romans, the following titles of Vestas, and had the perpetual fire committed to their charge. They were at first only four in number, but afterwards increased to six; and it does not appear that their number ever exceeded six, among whom one was superior to the rest, and called vestals maxima.

The vestals were chosen from six to ten years of age, and obliged to strict continency for 30 years: the first ten of which were employed in the ceremonies of religion, the next ten in the performance of them, and the tenth in teaching them to the younger vestals. The habit of the vestals consisted of an head-dres, called infilia, which sat close to their heads, and whence hung certain laces called vitae, a kind of surplice made of white linen, and over it a purple mantle with a long train to it.

VESTIBULE, in architecture, a kind of entrance into a large building; being an open place before the hall, or at the bottom of the staircase. Vestibules intended for magnificence, are usually between the court and the garden.

VESTRY, a place adjoining to a church, where the vestments of the minister are kept; also a meeting at such place where the minister, curthicas, and principal men of most parishes, at this day make a parish vestry. On the Sunday before a vestry is to meet, public notice ought to be given, either in the church, or after divine service is ended, or else at the church-door as the parishioners come out, both of the calling of the said meeting, and also of the time and place of the assembling of it; and it is reasonable they also declare for what business the said meeting is to be held, that none may be surprised, but that all may have full time before, to consider of what is to be proposed at the said meeting. Watts, c. 39.

VESUVIAN, a mineral found in lava, especially at Vesuvius, and formerly confounded with hycnath. Its colour is brown or yellow, being found in masses, but usually crystalized in rectangular eight-sided prisms. The primitive form of its crystals is the cube. The specific gravity is from 3.39 to 3.4. It scratches glass; the fracture is imperfect. It causes double refraction. Before the blowpipe it melts into yellowish glass. It is composed of

26.5 silica
40.2 magnesia
16.2 oxide of iron
16.0 lime

98.9

VETCH, See Vicia.

VIBRATION, in mechanics, a regular reciprocal motion of a body, as a pendulum, &c. which, being freely suspended, swings or oscillates, first this way, then that.

VIBRIO, a genus of vernes infusoria. The generic character is, worm invisible to the naked eye, very simple, round, elongated. There are 20 species enumerated, and found chiefly in vegetable infusions.

VIBURNUM, a genus of plants of the class Stammidophores, and in the natural system arranged under the 43rd order. The calyx is quinquepartite and above; the corolla divided into five laciniae; the fruit a monospermous berry. There are 33 species, two of which are natives of Britain.

1. The lantana, common vibrinnium, way-faring, or plant mealy tree, having white flowers, with eight-brown barks; large heart-shaped, veined, serrated leaves, white and hairy underneath, and the branches terminated by umbels of white flowers, succeeded by bunches of red berries, &c.

2. The opulus, or Guelder rose, consisting of two varieties, one with flat flowers, the other globular. The former grows 18 or 20 feet high, branching oppositely, of an irregular growth, and covered with a whitish bark: and large dilated or three lobed leaves on glandular footstalks. The latter has large globular umbles of white flowers at the ends of the branches in great abundance. This tree when in blossom exhibits a singularly fine appearance; the flowers, though small, are collected numerous into three globular umbels, round like a ball; hence it is sometimes called snow-ball-tree.

VICT, common vulgarus, or evergreen vibrinnium. There are a great many varieties of this different species of vibrinnium, both deciduous and evergreen kinds, nothing being of the tree kind, are woody and durable in root, stem, and branches. They may all be propagated by layers; and are of such a nature as to grow freely in the open ground all the year, in shrubberies, and other hardy plantations.

VICAR, one who supplies the place of another. The priest of every parish is called the vicar, unless the parochial tithes are appropriated, and then he is called vicar; and when rectories are appropriated, vicars are to supply the rector's place. For the maintenance of the vicar, there was then set apart a certain portion of the tithes, commonly about a third part of the whole, which are now what are called the vicarial tithes, the rest being reserved to the use of the rectors, which for the like reason are denominated the rectorial tithes.

VICARAGE. For the most part vicarages were endowed with tithes; but sometimes vicarages have been endowed without any appropriation of the parsonage; and there are several churches where the tithes are wholly appropriated, and no vicarage endowed; and there the impropriators are bound to maintain curates to perform divine service, &c. The persons, patron, and ordinary, may create a vicarage, and endow it; and in time of vacancy of the church, the patron and ordinary may do it; but the ordinary alone cannot create a vicarage, without the patron's assent.

VICE, in smithery, and other arts employed in metals, is a machine, or instrument, serving to hold fast any thing they are at work upon, whether it is to be filed, bent, rivetted, &c. To file square it is absolutely necessary that the vice should be placed perpendicular, with its chaps parallel to the workbench.

Vice, hand, is a small kind of vice serving to hold the lighter works in, that require often turning about.

Of these there are two kinds: the broad-chopped hand-vise, which is commonly used; and the square-nosed hand-vise, sel-
VINE

Of these boodmen or villeins, there were two sorts in England: one termed a villain in gross, who was immediately bound to the lord of the manor for life, or for the term of his or her life; the other a villein regardant to a manor, being bound to his lord as a member belonging and annexed to a manor wheresoever the lord was owner.

Both villains regardant, and villains in gross, were transferable by deed from one owner or tenant to another. They could not leave their lord without his permission; but if they ran away or were purloined from him, might be claimed and recovered by action like beasts, or indeed small portions of land to sustain themselves and families; but it was at the mere will of the lord, who might dispossession them whenever he pleased. A villain could acquire no property either in lands or goods; but if he purchased either, the lord might enter upon him, and seize them to his own use. 1 Black. 93.

VILLARIA, a genus of plants of the class pentandria, and order dioecia pentandria. The calyx has five purple, or violet, petals; and is a three-celled berry. It seems to be little known.

VINCA, in botany, a genus of plants of the class pentandria, and order monogynia; and in the natural system arranged under the name of Solanum. There are two species; and there are two erect follicles; the seeds are naked. There are five species, only two of which are natives of Britain: 1. The major, or great periwinkle. 2. The minor, or small periwinkle.

VINCUM, in mathematics, a character in form of a line, or stroke, drawn over a factor, divisor, or dividend, when compounded of several letters or quantities, to connect them, and shew they are to be multiplied, or divided, &c. together by the other term. Thus \(a + b\).

VINDICATRIX, or Vindicatrix, a fixed star of the third magnitude in the constellation Virgo, whose latitude is 16° 12' 34" north, and longitude 5° 37' 40" of Libra, according to Mr. Flamsteed's catalogue.

VINE. See Vitis.

VINEGAR. See Acid, Chemistry, Acetic, and Acetous Acid.

Vinegar was known many ages before the discovery of any other acid, those only existing which were formed in vegetables. It is mentioned by Moses; and indeed seems to have been in common use among the Hebrews, and other Eastern nations, at a very early period. It is prepared from wine, beer, ale, and other similar liquids. These are apt, as every one knows, to turn sour, unless they are kept very well corked. Now sour wine or beer is precisely the same with vinegar.

Boehmna describes the following method of making vinegar, as is said to be still practised in different places:

Take two large oakens vats or hogheads, and in each of these place a wooden grate or hurdle at the distance of a foot from the bottom, and in the grate place a moderately close layer of green twigs or fresh cuttings of the vine. Then fill up the vessel with the foothills of grapes, commonly called the rape, to the top of the vessel, which must be perfectly dry.

Having thus prepared the two vessels, pour into them the wine to be converted into vinegar, so as to fill one of them quite up, and the other half-full. Leave them thus for 24 hours, and then fill up the half-full vessel with liquid from that which is quite full. Four-and-twenty hours afterwards repeat the same operation; and thus go on, keeping the vessels alternately full and half-full during every 24 hours till the vinegar is made. On the second or third day the wine will arise, in the half-full vessel, a fermentative motion, accompanied with a sensible heat, which will gradually increase from day to day. On the contrary, the fermenting motion is still incomprehensible in the full vessel; and as the two vessels are alternately full and half-full, the fermentation is by that means, in some measure, interrupted, and is only renewed every other day in each vessel.

When this motion appears to have entirely ceased, even in the half-filled vessel, it is a sign that the fermentation is finished; and therefore the vinegar is then to be put into a close-stopped, and kept in a cool place.

All that is necessary to convert wine or beer into vinegar, is the contact of the external air, a temperature of 80°, and the presence of some substance to act as a ferments. Vinegar is a liquid of a reddish or yellowish colour, a pleasant sour taste, and a agreeable odour. Its specific gravity varies from 1.0135 to 1.0251, and it differs also in its other properties according to the liquid from which it has been produced. It is very subject to decomposition; but Scheele discovered that if it is made to boil for a few moments, it may be kept afterwards for a long time without alteration. Besides acetic acid and water, vinegar contains several other ingredients, such as mucilage, tarring, a colouring matter, and often also two or more vegetable acids. When distilled at a temperature not exceeding that of boiling water, till about two thirds of it have passed over, all these impurities are left behind, and the product is pure acid diluted with water.

The acid thus obtained is a liquid as transparent and colourless as water, of a strong acid taste, and an agreeable colour, somewhat different from that of vinegar. In this state it is usually called acetic or distilled vinegar. See Acetous Acid.

It may be preserved without alteration in close vessels. When exposed to a moderate heat, it evaporates completely, and without undergoing any change in its properties. When exposed to the action of cold, part of it congeals. The frozen portion, which consists almost entirely of water, may be easily separated; and by this method the acid may be obtained in a high degree of concentration. The more concentrated the acid is, the greater is the cold necessary to produce congelation. Mr. Lowitz has ascertained that the acid itself, how much soever it may be concentrated, crytalizes or congeals at the temperature of — .

When acet of copper, reduced to powder, is put into a retort and distilled, there comes over a liquid at first nearly colourless, and almost insipid, and afterwards a highly concentrated liquid. The distillation is to be continued till the bottom of the retort is dry. What remains in it is then only a powder of the colour of copper. The acid produced,
which should be received in a vessel by itself, is tinged green by a little copper which passes along with it; but when distilled over again in a retort, it is perfectly colorless and transparent. The acid thus obtained is exceedingly pungent and concentrated. It was formerly distinguished by the names of radical vinegar, and vinegar of Venice.

This acid is transparent and colourless like water. It has a peculiar aromatic smell when in the state of acetic acid: but concentrated acetic acid, when procured in the usual way, has a very perceptible, almost tobacco-like odor, mixed with the natural shell of vinegar, owing to a small portion of oil formed during the process.

A much easier method of obtaining acetic acid than that commonly used has been lately pointed out by Mr. Balhofer, apothecary at Chatteris.

All that is necessary is to distil a mixture of equal parts of acetate of lead and sulphat of copper in a glass retort. The acid comes perfectly pure on the application of a moderate heat.

The specific gravity of distilled vinegar varies from 1.007 to 1.0095; but radical vinegar is much more concentrated. In that state it is extremely pungent and acid; and when it is applied to the skin, it is reddish and corrodes it in a very short time. It is exceedingly volatile: and when heated in the open air, takes fire so readily, that one would be tempted to suspect the presence of ether in it. It unites faster than water in any proportion; and as it is more concentrated, the mixture evolves a good deal of heat. See ACID, CHEMISTRY, &c.

VINEYARD, a plantation of vines. See Vine.

The best situation of a vineyard is on the declivity of an hill, lying to the south. For the planting of a vineyard, observe the following method: In the month of July, while the outermost coat of the earth is very dry and combustible, plough up the sward; den- shire, or burn-beat it, according to art, and in January following, spread the ashes. The ground being thus prepared, cut your trenches across the hill, from east to west, because the vines being thus in ranks, the rising and setting of the sun will by that means pass through the intervals, which it would not do if they were set in any other position, neither would the sun dry its rays upon the plants during the whole course of the day.

Afterwards strain a line, and dig a trench about a foot deep; place your sets in it, about three feet distance one from another; trim off the superfluous roots, leaving no more than three or four eyes or buds upon that which is above ground; and plant them near half a foot deep, sloping, after the manner the quick is commonly set, so that they may point up the hill. That done, take long dung or straw, and lay it on the trenches in a convenient thickness to cover the earth, and preserve the roots from the dry piercing winds, which would otherwise much annoy them, and from the excessive searching heats in summer: keep them well hoed, and free from weeds, and water them as occasion serves; the best time to plant is in January.

The first pruning of the new-set vine ought not to be done, however, and till you should cut off all the shoots as near as you can, spar- ing but one of the most thriving, on which you are to leave only two or three buds, and so let all rest till May, the second year after planting. Take care then from time to time to destroy the weeds, and clear the roots of all suckers and old shoots, and to give the virtue of your sets. The same method is to be followed the third year; then dig your whole vineyard, and lay it very level, taking care in this operation not to cut or wound any of the main roots with your grades. If you have the younger roots, it is not so material, as they will grow the thicker; and this year you may enjoy some of the fruits of your vineyard, which, if answerable to your expectations, will tempt you to put your present plants and your vines of about four feet long, which must be placed on the north side of the plant. In May, rub off such buds as you suspect will produce superfluous branches. When the grapes are about the size of birding-shot, break off the branches with your hand at the second joint above the fruit, and tie the rest to the prop: here it is most ad- visable to break, and not cut, your vine; because wounds made with a sharp instrument are not apt to heal, but cause the plants to bleed. See PRUNING.

The fourth year you will be likely to have three or four shoots to every plant; and, in the fifth, many more, if kept in a proper state. The branches, except one of the strongest and most thriving, leave for a standard about four feet high, paring away the rest very close to the body of the mother-plant, which tie to your prop till it is large enough to make a standard of itself. Neither must you suffer any shoot to break out, but such as sprout at the top, four feet from the ground: all which sprouts the French usually prune off every year, and absolutely trust to the new sprouts that are only bearing shoots.

In August, when the fruit begins to ripen, break off such shoots as you find too thick; and if you perceive any plant bleed, rub some ashes on it; or, if that will not do, sear it with a hot iron. When, upon stirring your vineyard, it appears to be poor, prune the vines as before directed; and spread good dung, mixed with lime, over the whole surface of the ground in the winter to warm into the earth, mixing about ten bushels of lime with a load of dung; and if some ashes and soot are likewise thrown on, it will do well. Turn in this manure about the February, with a slight dressing of lime, on the top of the ground, but not too deep, which should be done in a dry season, and not in wet weather, lest it should make the ground bind too much, and occasion the growth of rank weeds.

VIOL, a stringed instrument resembling in shape and tone the violin, of which it was the origin; that impressive and commanding instrument being little more than an improve- ment of the old viol. This instrument formerly consisted of five or six strings, the tones of which were regulated by their being brought by the fingers into contact with the frets with which the neck was furnished. The viol was for a long while in such high esteem as to dispute the pre-eminence with the harp, espe- cially in the early times of music in France; and, indeed, being reduced to four strings, and stripped of the frets with which viols of all kinds seem to have been furnished till the six-teenth century; it holds the first place among treble instruments, under the denote- mination of violin.

VIOLA, a tenor violin. This instrument

is similar in its tone and formation to the violin; but its dimensions are somewhat greater, and its compass lower in the great scale of sounds. Its lowest note is C on the fourth space in the bass. The part it takes in concert is between that of the bass and the second violin.

VIOL, a genus of plants of the class syn- genesia, order monogynia; in the natural system arranged under the 29th order, cam- panaceae. The calyx is pentaphyllos; the corolla five-petalled, irregular, with a necta- rim behind, horn-shaped; the capsule is above the germen, three-valved, monocollicular. There are 43 species, six of which are natives of Britain. The most important of these are:

1. The palastris, marsh violet. The leaves are smooth, reeniform, two or three on each footstalk; flowers pale blue, small, inodorous.
2. The odorata, purple sweet violet, has leaves heart-shaped, notched; flowers deep purple, single; creeping scions. The flowers of this plant taken in the quantity of a dram or two, are said to be gently purgative or taxative, and, according to Bering and some others, they possess the small pectoral and vertebre quality. There is a variety with white flowers.
3. Tricolor, pansies, heart's-ear, or three faces under a hood. The stems are diffuse, procumbent, triangular; the leaves oblong, cut at the edges; the flowers purple, yellow, and light blue, inodorous. This elegant little plant merits culture in every garden, for the beauty and great variety of its three-coloured flowers; it will succeed in the open borders, or other compartments, espoused in patches towards the frost, either by sowing the seed at once to remain, or by putting in young plants. They form the flowers early in summer, and will continue shooting and flowering in succession till winter; and even during part of that season in mild weath- er. The common violet is propagated by parting the roots, sometimes by seed, but the well-known stringed instrument of brilliant tone and active execution. When, or by what nation, this important and interesting instrument was first invented, is not at present known; nor the form and change in the instrument used by the English in the time of Chaucer, who men- tions it, be exactlyascertained. There is, however, much reason for supposing that, from its first introduction it underwent con- tinual alterations and improvements, since even towards the end of the sixteenth cen- tury its shape appears to have been vague and undefined. It has, however, long attained its present excellence, and formed an integral part of every musical instrument. The four strings of which it consists are tuned in fifths from each other. The pitch of the lowest string is G, under the second ledger line in the treble stave; consequently that of the next is D, under the first line of the stave- the pitch of the next above that, A on the second space; and that of the upper string, E, on the fourth space. During the Protector- ship the violin was in little esteem, and gave place to the viol; but at the Restoration, violins began to be of fashion, and violins resumed their for- mer consequence. The antiquity of this instru- ment has long been a subject of dispute.
VIT

with the learned. It is generally supposed, and with much reason, that no instrument laid with the bow was known to the ancients.

VIOLONCELLO, a bass viol, containing four strings, the lowest of which is tuned to double C. The strings are in fifths, consequently the pitch of that next the gravest is $\frac{3}{4}$ an octave; that of the next, D on the third line in the bass; and that of the upper string, F on the fifth line. The violoncello was called the violoncini, a diminutive of the introduction of the double-bass, which assumed that name.

VIPER. See Coluber.

VIRGATA, a genus of plants of the

VIRGO, in astronomy, one of the signs or constellations of the zodiac, and the sixth according to order.

VISEREA. See Anatomy.

VISCUM, a genus of plants of the class Dioscoreaceae, order Tetradneida, and in the natural system arranged under the 46th order, aggregate. The male calyx is quadrinerved; the anthers adhere to the calyx; the female calyx is convex; the stigmas are of the style; the stigma is obtuse; there is no corolla; the fruit is a berry with one seed. There are 12 species, only one of which is a native of Britain, viz., the album, or common mistletoe. It is a shrub growing on the bark of several trees. The leaves are conjugate and elliptical; the stem forked; the flowers whitish in the axil of the leaves. This plant was reckoned sacred among the Druids.

VISION, in law, an act of jurisdiction whereby a superior, or proper officer, visits some corporation, college, church, or other public or private house, to see that the laws and regulations thereof are duly observed.

VITATUM, in law, a court of visitation performed by the bishop in every diocese once in three years, or by the archdeacon every year, by visiting the churches and their rectors throughout the whole diocese. The bishop or commendatory also holds a court of visitation, to which he may cite all churchwardens and wardens; and to whom he exhibits his articles, and makes inquiry by them.

VISMEA, a genus of the dodecandria trigny class and order of plants. The calyx is five-leafed, inferior; the corolla five-petalled; stigmas five; nect. two or three-celled. There are two species, a native of the Canaries.

VITEN, the chaste-tree, a genus of the

didynamia angiosperma class of plants, with a monopetalous ring, and bilabiated flower, each lip of which is tripart; the fruit is a quadrilocular, globose berry, containing four seeds. There are 14 species.

VITIS, a genus of the class pentandria, and order monogynia; and in the natural system arranged under the 46th order, pectoracea. The petals cohere at the top, and are withered; the fruit is a berry with five seeds. There are 25 species; the most important of which is the vinifera, or common

VINE, which has naked, lobed, sinuate leaves. There are many great varieties; but a reclass of their names would be tiresome without being useful. All the sorts are propagated by cuttings or grafting, the former of which methods is generally practised in England, but the latter is much preferable.

In choosing the cuttings, you should always take such shoots of the last year's growth as are strong and well ripened; these should be cut from the old vine, just below the place where they were produced, taking a knot or piece of the two years' wood to each, which should be pruned smooth; then you cut off the upper part of the shoots, so as to leave the cutting about 16 inches long. When the piece or knot of old wood is cut at both ends, near the young shoot, the cutting will resemble a little mallet; whence Colonna gives the title of malletus to the vine-cuttings.

In making the cuttings after this manner, there can be but one taken from each shoot; but most persons cut them into lengths of about a foot, and plant them all.

When the cuttings are properly prepared, if they are not then planted, they should be placed with their lower part in the ground in a dry soil, laying some litter upon their upper parts to prevent them from drying. In this state they may remain till the beginning of April (which is the best time for planting them); when you should take them out, and wash them from the filth they have contracted; and if you find them very dry, you should let them stand in small pans of water six or eight hours, which will disentend their vessels, and dispose them for taking root. If the ground is strong and inclined to wet, you should open a trench where the cuttings are to be planted, which should be filled with lime-rubbish, the better to drain off the moisture; then raise the borders with fresh light earth about two feet thick, so that it may be at least a foot above the level of the ground; then you should open the holes at about six feet distance from each other, putting one good strong cutting into each hole, which should be laid a little sloping, that their tops may incline to the wall; but it must be kept so deep, that the eye may be level with the surface of the ground; for when any part of the cutting is left uppermost, most of the buds attempt to shoot, so that the strength of the cuttings is divided among many; and consequently be weaker than if only one of them grew; whereas, by burying the whole cutting, the sap is all employed on one single shoot, which consequently will be much stronger; besides, the sun and air are apt to dry that part of the cutting which remains above ground, and so prevent the buds from shooting.

Having placed the cutting in the ground, fill up the hole gently, pressing down the earth with your foot close about it, and raise a little hill just upon the top of the cutting, to cover the upper eye quite over, which will prevent it from drying. Nothing more is necessary than to keep the ground clear from weeds until the cuttings begin to shoot; at which time you should look over them carefully, to rub off any small shoots, if such are produced, first射击 the main shoot to which they are attached, which should be tied up as the vine is extended in length, to prevent its breaking or hanging down. You must con-
received at least three or four tons of wine annually as tithe, from the produce of the vineyards in his diocese, and to have made free remissions in his leases of a certain quantity of wine for it. In the reign of King Edward IV., the vineyards in London, which now forms East Smithfield, and some adjoining streets, was withheld from the religious house within Aldgate by four successive constables of the Tower, in the reign of Richard Henry, and Stephen, and made by them into a vineyard, which yielded great emolument. In the old accounts of rectorial and vicarial revenues, and in the lists of episcopal and ecclesiastical suits concerning them, the title of wine is an article that frequently occurs in Kent, Surrey, and other counties. And the wines of Gloucestershire, within a century after the Conquest, were little inferior to the French in sweetness. The beauty of their fruit appeared till the 15th century, when they had not a single vine in the days of Caxton, had numbers so early as the time of Strabo. The south of it was particularly stocked with them; and they had even extended themselves into the interior parts of the country, but the grapes of the latter did not ripen kindly. France was famous for its vineyards in the reign of Vespasian, and even exported its wine to Egypt. The whole province of Narbonne was then covered with vines, and the vine-wine of the country were remarkable for knavish dexterity, tinging it with smoke, colouring it (as was suspected) with dried and noxious dyes, and even adulterating the taste and appearance of it. It was, no doubt, a remarkable fact, that as our first vines would be transplanted from Gaul, so were in all probability those of the Allobroges in Franche-comté. These were peculiarly fitted for cold countries. They ripened even in the frosts of the advancing winter; and they were of the same colour, and seem to have been of the same species, as the black muscadines of the present day, which have lately been tried in this island, and found to be fittest for the climate. These were probably brought into Britain a little after the vines had been carried over all the kingdoms of Gaul, and about the middle of the 1st century, when the numerous plantations had gradually spread over the face of the latter, and must naturally have contributed to their progress into the former.

The Romans, even nearly to the days of Lucullus, were very seldom able to regulate themselves with wine. Very little was then raised at the compass of Italy; and the foreign wines were so dear, that they were rarely produced at an entertainment; and when they were, each guest was indulged only with a single draught. But in the seventh century of Rome, as their conquests augmented the degree of their wealth, and enlarged the sphere of their luxury, wines became the object of particular attention. Many vats were constructed, and good stocks of liquor were deposited in them; and this naturally gave encouragement to the wines of the country. The Falernian rose immediately into great repute; and a variety of others, that of Florence among the rest, succeeded it about the close of the century; and the more westerly parts of the European continent were at once subjected and enriched with the wines of Italy. See VINEYARD, and WINE.

VITIMANNA, a genus of plants of the class and order octandria monogynia. The calyx is four-leaf; corolla four-petalled; stamens, the scale of the base of each filament, is semi-anther, one-celled. There is one species, a tree of the East Indies.

VITREOUS humour of the eye. See OPTIC.

VITRIOL, or sulphur of iron. This salt was known to the ancients, and is mentioned by Pliny under the names of pyrosyris, and calcanthum. In commerce it is usually denominated green vitriol, or copper vitriol. It is not prepared by dissolving iron in sulphuric acid, but by moistening the pyrites which are found native in abundance, and exposing them to the open air. They are slowly covered with a crust of sulphate of iron, which is dissolved in water, and afterwards obtained in crystals by evaporation. Sometimes the salt is found ready-formed, either in a state of solution in water, or mixed with decayed pyrites. In some cases it is found necessary to roast the pyrites before they can be melted, to undergo spontaneous decomposition. This is most probably owing to the compact state of the pyrites in these cases, and the absence of all combined iron. Pyrites is in fact a supersulphuret of iron, or a sulphate of iron. These species of the earth are generally found in the state of a sulphuret of iron, which decomposes very readily.

Sulphate of iron has a fine green colour. Its crystals are transparent rhomboidal prisms, the faces of which are rhombi with angles of 70° 30' and 109° 10', inclined to each other at angles of 98° 37' and 81° 27'. It has a very strong styptic taste, and always reddens vegetable juices. Its specific gravity is 1.3939. It is soluble in about two parts of cold water, and in thirds of its weight of boiling water. It is insoluble in alcohol.

VITRIOL, blue, or sulphate of copper. Sulphuric acid does not attack copper while cold, but at a boiling heat part of the acid is decomposed, the copper is oxidized, and combines with the remainder of the acid. But recourse is seldom had to this process, as the sulphate of copper is found native abundantly, dissolved in mineral waters connected with copper-mines. From these waters it is often obtained by distillation; or it is formed by burning native copper, or by moistening that substance, and exposing it to the air. By either of these methods the sulphur is added, and the sulphate of copper formed. It then appears to have been known to the ancients. In commerce it is distinguished by the name of blue vitriol, and sometimes by that of blue copperas. It is, in fact, an oxysulphate. There are two varieties of this salt known, namely, super-sulphate, and subsulphate.

VITRIOL, white, or sulphate of zinc. This salt, according to the best accounts, was discovered at Rammelsberg in Germany about the middle of the 16th century. Many ascribe the invention of it to the Duke of Brunswick. Henkel and Newmann were the first chemists who proved that it contained zinc; and Brandt first ascertained its composition completely. It has generally been formed for commercial purposes, to supply the sulphate of zinc, or blende, as it is called by mineralogists. This ore is roasted, which converts the sulphur into an acid; it is then dissolved in water, and concentrated, so that, on cooling it crystallizes very rapidly, and forms a mass not unlike laid-sugar. This salt is usually called white vitriol. It is almost always connected with iron, and often with copper and lead. Hence the spots which are visible on it, and hence also the reason that in its solution in water lets fall a dirty-brown sediment; a circumstance very much explained by surgeons when they use that preparation. The solution is then to be evaporated, and the sulphate of zinc may be obtained from it in crystals by proper evaporation.

We have inserted these three articles under the vulgar names in compliance with a common prejudice. They are, however, noticed under their proper head; and a true advancement of chemical knowledge will shortly banish these barbarous terms.

VITUS'S DANCE. See MEDICINE.

VIVERRA. See MEDICINE.

VIVERRA, or Family of Quadrupeds of the order of foxes. The generic characters are--teeth six, sharpish; canine teeth longer; tongue in some smooth, in others acutated above; body of a lengthened form. This genus comprehends certain species of the viverrine and linncean family, in which latter genera the otters are also included. This particular species, Mr. Pentrant seems to have named judiciously, for it is certainly viverrine.

We shall therefore follow his example, and unite the two genera, preserving the name Viverra, in contradistinction to the generic name Mus, which is smaller.

The general character of the viverrine tribe (of which there are about 31 species) is, a certain slenderness and length of body; with a shaggy visage, short legs, and, in most species, a longish tail (though in some few it is short).

1. Viverra Ichneumon. The ichneumon is a species of which there seem to be two distinct varieties, one of which is a native of India, and the other of Africa. The African is by far the larger in their general appearance, but the Indian variety is considerably larger than the Indian, measuring more than forty inches from the point of the tail to the end of the same; whereas the Indian ichneumon scarcely reaches one-third of this length. Exclusive of size alone, the Egyptian ichneumon is distinguished by having the tail slightly tufted at the end, which the other has not; and from this circumstance it is placed, in the Ometian edition of the Systema Naturae, as a distinct species. The ichneumon is of a pale reddish-grey colour, each hair being mottled with brown or dusky spots, so that the whole appears speckled in the manner of the hair on some of the large baboons. The eyes are of a bright red or flame-colour; the ears rounded, and almost closed; the nose long and slender; the body rather thicker than in most of this genus; and the tail is very thick at the base, and then gradually tapers almost to a point; the legs are short; the hair on the whole animal is bristled, and coarse, and it varies somewhat as to the colour and cast of its colours in different individuals. In India, but particularly in Egypt, the ichneumon has always been considered as one of the most useful and estimable animals; since it is an inveterate enemy to serpents, rats, and other noxious creatures.
which infest those regions. In India it attacks, with the greatest eagerness and courage, that most dreadful reptile the cobra de pellejo, or hooded snake, and easily destroys it. It also haunts the woods for the eggs of serpents and crocodiles; for which reason, as well as for its great usefulness in destroying all manner of troublesome reptiles, it was held in such a high degree of veneration by the ancient Egyptians to be regarded in the light of a minor deity, one of those benevolent beings proceeding from the parent of the universe.

For the purposes above specified it is still domesticated by the Indians and Egyptians; and it has also the merit of being easily tamed, and of performing all the services of the cat with a still greater degree of vigour and acuteness. When in pursuit of prey, it sometimes springs suddenly upon it with the greatest agility; and at other times will glide along the ground like a serpent, without raising its body, till it arrives at a proper distance for its intended attack. Of the other animals of this genus, the most dangerous enemy to several creatures larger than itself; over which it gains a ready victory, by fastening itself upon them, and sucking their blood. In a word, it is the principal agent in the banks of rivers; and in times of flood to approach the higher grounds and inhabited places, in quest of prey. It is reported to swim and dive occasionally, in the manner of the otter; and to continue beneath the water for a great length of time.

The ichneumon is found not only in various parts of India, but in the Indian islands, as Ceylon and others. It also occurs in many parts of Africa besides Egypt, as in Barbary, and at the Cape of Good Hope, &c. &c. as it is a native of warm countries, it is of course greatly injured by a removal to the colder regions of Europe, and generally falls a victim to the alteration of climate. See Plate Nat. Hist. fig. 418.

2. Viverra surikatta. The surikata is distinguished by a long sharp-pointed nose, depressed head, and inclined cheeks; the upper jaw is much longer than the lower, and on its upper part, the lower jaw is shorter; the tail is round black; the ears are small and rounded; the tongue is oblong, blunt, and acutated backwards; the length of the animal, exclusive of the tail, is about a foot, and of the tail about eight inches; the legs are short; the claws on the fore feet much exceed in length those of the hind feet. The general colour of the surikata is a deep grey; the tail is subferruginous, tipped with black. It is an inhabitant of the Cape of Good Hope, where it is called meerkat. It feeds on fresh, and preys on mice, and other small animals. It commonly sits erect, in the manner of a squirrel; and when pleased makes a rattling noise with its tail, for which reason it is also surikata. It is also found in the islands of Java, where it is named surikatje by the Dutch, on account of a peculiar acid scent, which it is said to emit. It is an inhabitant of the Cape of Good Hope, and is often seen in a state of captivity. In having only four toes, it differs from most of this tribe.

3. Viverra nausa. The size of this animal is at least equal to that of a cat. Its general colour is a cincereous brown, or ash-colour, with a cast of reddish; the tail, which is of very considerable length, is annulated with short biting circles of black; its most remarkable character is the long, flexible snout, somewhat truncated at the end. By the assistance of this it turns up the earth, in the manner of a hog, in quest of earthworms, &c. Like the polecat, it also preys on the smaller quadrupeds, birds, &c. It is a native of South America, and seems to have been first described by Mariegrave in his History of Brazil. There is a particularity sometimes observable in this animal, which seems worthy of notice, viz. a kind of protrusion of the skin at the back of the heel into several horny processes, of about a quarter of an inch in length; these in some specimens are scarcely visible. The tongue is marked on the upper part with several furrows, so disposed as to resemble the fibres of a leaf.

4. Viverra vulpulca. Coarse. This animal is about the size of the polecat, measuring 18 inches from nose to tail. The tail is long and slender. The whole animal is of a deep black, or blackish chocolate-colour, but the tail is sometimes mixed with white. It is a native of Mexico and many other parts of America, and colours the power of emitting its oil, when attacked or irritated, such powerful offensive effluvium, as, in most instances, effectually to disinfect and repel its pursuers.

5. Viverra striata. Striped weasel. It has been imagined, and not without a degree of probability, that this animal is the female of Viverra vulpulca, or coase. It is of the same size and general aspect, but is distinguished by five parallel longitudinal white stripes on the back; the tail is very bushy or full of hair. In the different specimens of this animal there is some slight variation observable in the proportion of the dorsal stripes, as well as in the colour of the tail, which is sometimes marked with a pair of lateral white bands, and sometimes almost entirely white. Its manners and horrid va pour, when irritated, perfectly agree with the viverra vulpulca; and the same description of this offensive quality may be applied to some other species. It seems as if, on account of this odious vapour are not aggravated by the abhorrent recollection of those who have experienced its effects, every other ill smell which nature can produce is surmounted by the overpowering force of these extraordinary quadrupeds. In consequence of the dreadful emanation, the dogs are said to relinquish their pursuit, and the men toly with precipitation from the tainted spot; and if unfortunately the last particle of the fluid which the animal commonly discharges at this juncture, should happen to light on the clothes of the hunter, he becomes a general nuisance wherever he appears, and is obliged to divest himself of his dress, and practice all the arts of ablation, in order to be restored to the society of mankind.

To add to the history of these strange circumstances, it is affirmed that the animal is sometimes turned, and rendered domestic, in which state it is to be considered as a pet. It has a subglandular vesicle, or gland of a peculiarly acid and caustic nature, which is used in medicine, in the same state of a powder, and is also used in the preparation of unguents and perfumes. It is said that the Chinese, the Malays, and the inhabitants of the Cape call it klapper-maus. It is also found in the islands of Java, where it is named surikatje by the Dutch, on account of a peculiarly acid scent, which it is said to emit. It is an inhabitant of the Cape of Good Hope, and is often seen in a state of captivity. In having only four toes, it differs from most of this tribe.

6. Viverra capensis. The Cape weasel, or one of the larger animals of the genus, measuring two feet from nose to tail, which is eight inches long. Its colour is a cincereous grey above, and brownish black below; the two colours being separated along the whole length of the animal, from the head to the tip of the tail, by a stripe of the same white; the ears are scarcely visible; the tail rather thick; the legs rather short, and the head large; the snout short and somewhat pointed; the body seems of a thicker form than is usual in this genus. This animal, when irritated, ejects a fetid liquid, accompanied by a smell as insufferable as that of some of the American weasels or skunks, and productive of the same effects.

7. Viverra ceylon. The ceylon viverra, or civet, by the name of the civet-cats, is a native of several parts of Africa and India. The general length of this animal, from nose to tail, is something more than two feet, and the tail measures fourteen inches. The greater part of the body is yellowish ash-grey, marked with large blackish, or dusky spots, disposed in longitudinal rows on each side, and sometimes a tinge of ferruginous appears intermixed, the hinder parts, and along the top of the back stand up, so as to form a sort of mane; the head is of a lengthened or sharpish form, with short rounded ears; the eyes are of a bright sky-blue; the tip of the nose black, the sides of the face, chin, breast, legs, and feet, are black; the remainder of the face, and part of the sides of the neck, are of a yellowish white; from each ear are three black stripes, terminating on the tip and shoulders; the tail is generally black, but sometimes is marked with pale or whitish spots on each side the base. It is an animal of a wild disposition, and lives in the usual manner of others of this genus, as it feeds on carrion, noisily quadrupeds, &c. It is remarkable for the production of the drug called civet (sometimes erroneously confounded with musk). This substance is a secretion formed in a large double glandular receptacle, situated at some little distance beneath the tail, and which the animal empties spontaneously. When the civet-cats are kept in a state of confinement (as is usual with the perfumers at Amsterdam and other places), they are induced by time, in strong wooden cages or receptacles, so constructed as to prevent the creature from turning round and biting the person employed in collecting the secreted substance: this operation is said to be generally performed twice a week, and is done by scraping out the civet with a small spatula, or sponge. This substance is of a yellowish colour, and of the consistence of an unguent; of an extremely strong and even unpleasant odour when fresh, so as sometimes to cause giddiness and headache, but becomes more agreeable by keeping; the quantity obtained each time amounts about a dram.
VIVERRA.

8. Viverra zibetha. Zibet. This, which is figured as a variety by Geay, and more precisely discriminated by Buffon, seems to be considered by modern naturalists as a distinct species. The zibet is chiefly found in Asia and the Indian islands. Its general spact is similar to that of the forms species, but its snout is somewhat sharper, and its tail longer.

In short, this species may be called the Indian, and the former the African, civet.

In disposition and manners they both appear to agree, as well as in the secretion of the perfume before described, which is collected from both animals in the same manner.

9. Viverra geneetta. The geneet is one of the most beautiful animals of this genus. It seems to be of the size of a very small cat, but is, on the contrary, a form with a sharp-pointed snout, bright eyes, slightly pointed, and very long tail.

The colour of the geneet is generally light reddish gray, with a black or dusky line running along the back, where the hair is much longer than on the other parts, and from the appearance of a very slight shine among the sides of the body run rows of roundish black spots, which sometimes in- clude the tail to a squarish form; the muzzle is dusky; beneath the eye is a white spot; the cheeks, sides of the neck, and the hairs of the ears are spotted in a proportionally smaller pattern than the body, and the tail is annulated with black.

The geneet is an animal of a mild disposition, and easily tamed. In various parts of the East, as well as in Constantinople, it is domesticated like the cat, and is said to be equal, or superior, to that animal in clearing houses from rats or mice. It is a cleanly animal, and has a slight musky smell. It is a native of the western parts of Asia, but is said likewise to occur in Spain, and even occasionally in some parts of France.

10. Viverra fossa. The fossa appears to be closely allied to the geneet, that it might almost pass for a variety of that animal. This animal is a native of Madagascar, Guiana, Bocas, Cochininha, and the Philippine Islands. It is said to be possessed of considerable strength, and to be very difficult to tame. It destroys poultry in the most ruinous manner.

The fossa is a large animal, having a prehensile tail, ten inches in length from the nose to the throat, which is seventeen inches long. The nose is short and dusky; the eyes small; the ears short, broad, and hairy, and placed at a great distance from each other; the head flat and broad; the cheeks swelling out, the tongue very long; the legs and thighs short, thick, with five toes to each foot; claws are, slightly hooked, and flesh-colored, to court yelpers. A skilful or dexterous hunt runs down the back, on the tail to tail, and a similar one half way from the belly. This animal is of gentle manners, active and playful, and hangs by its tail, the manner of the prehensile-tailed monkeys. It is supposed to be native of Jamaica.

11. Viverra foina. The foina is a small animal of a highly elegant appearance. Its general length, from nose to tail, is about the height of a botanic half, and the tail is ten inches long.

The maron is of a blackish tawny colour, with a white throat; and the belly is of a dusky brown, with a lilac, or full of hair, and of a darker colour than the dusky parts; the ears are moderately large and rounded, and the eyes lively. This animal is a native of most parts of Europe; inhabiting woods and thickets, and preying on birds and other small animals. If taken young, it may be easily tamed, and even rendered domestic. It breeds in the hollows of trees, and brings forth from three to five young.

The skin of the foina is valuable.

12. Viverra zibellina. The sable is greatly allied to the maron in its appearance, but has a longer or sharper head, and more lengthened ears. Its general colour is a deep glossy brown; the hair being ash-coloured at the roots and black at the tips; the chin is cinereous, and the edges of the ears yellow. Its size is equal to that of the maron; but, exclusive of other differences, a principal one consists in the tail, which is much shorter in the sable than in the maron. The sable is an inhabitant of the northern parts of Asia, and is an extremely important article in the fur-trade. It principally lives in holes under ground, especially under the roots of trees, which, like the maron, forms its nest in the hollows of trees. It is an active, lively animal, preying, in the manner of the maron, on the smaller quadrupeds, birds, &c. Like the maron, it is also more lively during the night, and sleeps much by day. In autumn the sable is said to eat cranberries, whortles, &c. It brings forth early in the spring, and has from three to five young at a time. The chase of the sable, according to Mr. Pennant, was, during the more barbarous periods of the Russian empire, the principal task of the unhappy exiles who were sent into Siberia, and who, as well as the soldiers sent there, were obliged to furnish, within a given time, a certain quantity of furs; but as Siberia is now become very populous, the sable have a great measure quitted it, and have retired farther to the north and east, into the desert, forests, and mountains.

Sables are numbered among the most valuable of furs. From an abstract drawn up by the late Dr. Forster, from Muller's account of its commercial history, it appears that the price varies, from one to ten pounds sterling and above. The blackest, and that which have the finest bloom or gloss, are repented the best. The very best are said to come from the confines of Norway and Yakutsk, and in this latter district the country about the river Ud sometimes affords sables of which a single fur is sold at the rate of sixty or seventy rubles, or twelve or fourteen pounds sterling. Sometimes the furs of sables are fraudulently dyed, and otherwise prepared, in order to give them a more rich or mottled colour, but these are very inferior to the finest natural ones, and are distinguishable by a kind of withered or dull appearance of the hair itself when accurately inspected.

This sable occurs in North America, as well as in Asia. An Indian sable is said to be chiefly of a chestnut-colour, and more glossy, but coarser, than the Siberian sables. It is necessary to observe, that the sable varies in its cast of colour at different seasons and in different districts; instances have been known, though rarely, of its being found perfectly white.

13. Viverra putorius. The porcupine is one of the largest European species of the weasel tribe. Its tail is extremely deep blackish-brown, with a tawny cast slightly intermixed; the ears are edged with white, and the space round the muzzle is also white. The general length of this animal is seventeen inches, exclusive of the tail, which measures about six inches. The porcupine is found in most parts of Europe, as well as in some of the Asiatic regions, as in Siberia, where it is said to be generally found with the rump of a whistling or yellowish tawny, sur- rounded with black.

The porcupine commonly forms itself a subterraneous retreat, sometimes beneath the roots of large trees, and sometimes under hay-ricks, and in barns. It preyed indiscriminately on the smaller animals, and is very destructive to poultry; it is also, like the ferret, a cruel enemy to rabbits, which it destroys by bleeding them immediately in pieces. It steals into barns, pigeon-houses, &c., where it occasionally makes great havoc; biting off the heads of fowls and pigeons, and then carrying them away. It is said sometimes to carry off the heads of geese; and sometimes it carries off the heads of swine and the necks of the summer, however, it principally frequents rabbit-warrens, or the hollow trunks of trees; &c. and prows about in quest of young birds, etc., etc., etc. According to Mr. Pennant, the count de Buffon, and a single fact of his, it is said that the porcupine is sufficient to destroy a whole warren of rabbits; and he observes, that this would be a simple method of diminishing the number of rabbits where they are too abundant. In Spain the ferret is said to have been formerly introduced for a similar purpose. The porcupine also preys occasionally on fish, of which a curious instance is recorded in Mr. Beck's History of Quadrupeds.

During a severe storm, one of these animals was tracked in the snow from the side of a rivulet to its hole, at some distance from it; as it was observed to have made frequent trips, and as other marks were observed, which could not easily be accounted for, it was supposed to be a matter worthy of more diligent enquiry; its hue was accordingly examined, the animal taken, and eleven fine eels were discovered to have been covered with the fruits of its former excursion; the unusual marks in the snow were made by the motion of the eels while dragged along in the animal's mouth. That the porcupine, however, sometimes feeds in this manner, is, in reality, no observation; since Aldrovandus assures us that it will occasionally take up its residence in the hollow banks of rivulets, in order to lie in wait for, and prey upon, fish. The porcupine is also distinguished by a milk, which is said to be white, and to acid the dairy, in order to indulge in this article. It has been known to attack bee-hives in the winter season, and to feed on the honey. The spring is the season in which it breeds; the female producing three or four at a birth, which she is said to suckle but a short time, accustoming them early to suck the blood of the animals which she brings to them, as well as eggs.

The porcupine has been known to breed with the ferret; and it is said to be a practice with warreners, who keep these animals, to procure a mixed breed from time to time, which
are of a colour between the ferret and the polecat, or of a dullish yellowish-brown.

The ferret a lively creature, and will spring with great vigour and celerity when preparing to attack its prey, or to escape from pursuit, at which time it arches its back considerably, in order to assist its efforts to escape. A petty field, being furnished, like several others of the weasel tribe, with certain receptacles which secrete a thickish fluid of a peculiarly strong and offensive odour. The fur, however, is beautiful, and the skin, when properly dressed, is numbered among the commercial furs, and used for tippets and other articles of dress. It is added by Aldrovandus, that the furriers endeavour to obtain skins taken from such animals as have been killed during the winter, as being far less feathery than those killed in the spring and summer.

15. *Viverra ferox*. Ferret. Of similar manners to the polecat is the ferret, the natural history of which has been so well detailed by the Count de Buffon, that it is scarcely possible to add any thing material to that elegant author's description. The ferret in general form resembles the polecat, but is a smaller animal, weighing about seven ounces, and measuring about nine inches, exclusive of the tail, which is about five. Linnaeus, in the twelfth edition of the Systema Natœae, seems to entertain a doubt whether it is truly distinct from the polecat; it is, however, a native of Africa, and not of Europe, and supports with difficulty the cold of an European winter; whereas the polecat is found not only in the temperate, but also in the colder parts of the European continent, of which many species are found, that, exclusive of its smaller size, it is of a more slender shape, and the snout is sharper in proportion than in the former animal. The ferret is used for rabbit-hunting in preference to the polecat, because it is more easily trained; but it is necessary to keep it in a warm box, with wood, or some other substance, in which it may imbibe itself. It sleeps almost continually, and when awake, immediately goes to sleep. It is usually fed with bread and milk; but its favourite food is the blood of the smaller animals. It is by nature an enemy to the rabbit; and it is affirmed by Buffon, that it is a animal, which after its first time to a young ferret, he flies upon it in an instant, and bites it with great fury; but if it is alive, he seizes it by the throat, and sucks its blood. When let into the burrows of rabbits, the ferret is always muzzled, that it may not kill the rabbits in their holes, but only drive them out, in order to be caught in the nets. If the ferret is put in without a muzzle, or happens to disembowel himself from it, he is often lost: for, sucking the blood of the rabbit, he falls asleep, and cannot be regained, except sometimes by smoking the hole, in order to oblige him to come out; but as this is a practice which does not always succeed, it continues to lead a rapacious and solitary life in the warren, as long as the summer continues, and perishes by the cold of the winter.

We are told by Strabo that the ferret was brought from Africa to Greece; and it is supposed that this was done in order to furnish that country from the vast number of rabbits with which it was over-run; and from Spain it was gradually introduced into other European countries. The ferret is an animal of an irreproachable nature, and, when irritated, its colour, which is all at times disagreeable, becomes its chief mark. The general colour of the ferret is a pale yellowish-brown, or cream-colour; and the eyes are of a bright and lively red.

16. *Viverra vulgaris*. Common weasel. One of the smallest species of this numerous tribe of quadrupeds. Its general length is about seven inches, exclusive of the tail, which measures near two inches and a half. Its colour is a pale reddish, or yellowish-brown, and beneficial in winter; but below the corners of the mouth, on each side, is a brown spot: the ears are small and rounded, and the eyes are black. This little animal is possessed of a considerable degree of elegance in its aspect, and its audacity is light and easy; but it has the same unpleasant smell with the stoat, and some other species. It is an inhabitant of the cavities under the roots of trees, as well as of humps near rivulets, &c., and occasionally sallies out in quest of birds, field-mice, &c. It even attacks young rabbits, and other animals of far superior size to itself; but its chief prey, at least in this country, seems to be the common field-mouse, which it pursues with great rapidity. From the extreme flexibility of its body, and its wonderful activity, it readily ascends the sides of walls, and by this means escapes its prey into the most distant retreats; and in a short instant the most of birds and grannies. The weasel produces four or five young at a time; preparing for them a bed of moss, grass, &c. An instance is given by the count de Buffon of a weasel's nest being found in the carcase of a wolf, which had been hung up near a wood; the nest was made in the cavity of the thorn. The count de Buffon, in his first description of the weasel, affirmed that it was a perfectly harmless animal; but he afterwards received very authentic accounts of weasels which had been so completely tamed as to exhibit every mark of attachment to their breeders, and to be as familiar as a cat or lap-dog; and that one of his correspondents gave a specimen of one of his correspondents in the seventh supplementary volume of his Natural History, which amply confirms the truth of this; and among other curious particulars, it is observed, that of the little animal which exists in a state of extreme flaccidity, so that it may be taken up by the head, and swung backwards and forwards, in the manner of a pendulum, several times, before it wakes.

17. Viverra erminea. Stoot. This animal much resembles the weasel in its general appearance, as well as in colour, but is considerably larger; the body, exclusive of the tail, measuring ten inches, and the tail five inches and a half; the tip of the tail is also constantly black, whatever may be the gradation or cast of colour on the body; for the stoot, in the northern regions, becomes milk-white during the winter, in which state it is commonly called the ermine. It is sometimes found of this colour in our own country; and instances are not very uncommon in which it appears parti-coloured, or white in the summer, and the change of colour having not been completed. Its smell is strong and unpleasant. The stoot is similar in its manners to the weasel, living in hollows under the roots of trees, in banks near rivulets, &c. and preying on all manner of smaller animals, as well as on rabbits, &c. It is not a curious animal. It is a common weasel, not hunted, but consines itself to the fields. It is an inhabitant both of the northern part of Europe and of Asia. It occurs in Katschatka and the Kurile islands. It is also to be found in several parts of North America.

In Norway and in Siberia the stoat is a great article of commerce; most of ther-
ULNA. See Anatomy.
ULVA, a genus of plants of the class cryptogamia, and order of algae. The fruticulose
viscous, and phaeophyceous membrane.
There are 26 species of British plants. They are all sessile, and without roots, and grow in
mounds, and on stones along the sea-coast.
None of them are applied to any particular use different from that of the algae which
are the unbluish, which in England is pickled with salt, and preserved in jars, and afterwards
steamed and eaten with oil and lemon
juice. This species, called in English the
mouldy layer, is flat, orbicular, sessile, and
co-ameous.
UMBELLE, umbels, among botanists, the round tufts or heads of certain plants set
thick together, and all of the same height.
UMBELLIFEROUS PLANTS, are such as have their tops branched and spread out like
an umbrella, on each little subdivision of which there grows a small flower; such
are fennel, dill, &c. See Botany.
UMBER, or UMBRE, umbria, among painters, &c., a kind of dry dusky-coloured
earth, which, diluted with water, serves to make a dull-colour, generally called with the
hair-colour. It is called umbre, from umbra, a shadow, as serving chiefly for the
shading of objects; or, perhaps, from Uhmbria a country of Italy, whence it was used
to be brought.
UMBER, or grayling, in ichthyology. See
Salmo.
UNCARIA, a genus of plants of the class and order pentandria monogynia. The corolla is
valve-shaped; germ. crowned with a gland; stigma two-keeved, pere. two-celled, many-
seeded. There are two species.
UNCIA, in general, Latin term denoting the twelfth part of any thing, particularly
the twelfth part of a pound, called in English an ounce; or the twelfth part of a foot, called
an inch. See Measure, and Weight.
UNCLE, in algebra, the numbers prefixed before the letters of the members of any
power produced from a binomial, residual, or monomial. Thus, in the earth power
of a-b, viz. a"b^-a^-b^-a^-b-^-b, the
uncies are 4, 6, and 4, being the same with what
other call coefficients. See Algebra.
UNDECAGON, is a polygon of eleven sides; a regular undecagon is 1, its area will be 9.306.690 = \(\frac{11}{73.2}\) square
degrees; and therefore if this number is
multiplied by the square of the side of any
other regular undecagon, the product will be
the area of that undecagon.
UNGUIS. See Anatomy.
UNGULA, in geometry, is a part cut off
from a cylinder, cone, &c., by a plane passing
obliquely through the base, and part of the
surface of the cylinder, so called from its resemblance to the (ungula) hoof of a horse, &c.
UNGULATED. See FISH. See NOWDON.
UNIOLA, or the triandra digyna class of plants, the corolla whereof consists of a bivalve
plume; the valves are of a lacerated-cone shaped figure, like those of the
clam; the inner valve appears somewhat higher than the outer one; the corolla perfoms the
office of a pericarpium, inclosing the
seed, which is single, and of an ovated
oblong figure. There are three species.
UNION, in music, that consonance, or coincidence of sounds, proceeding from an
equality in the number of vibrations made in a
given time by two sonorous bodies; or the
union of two sounds so directly similar to
each other in respect of gravity, or acute-
ess, that the ear perceiving no difference,
receives them as one and the same.
The antist are much disputed in opinion
respecting the question whether the union is a
consonance. Aristotle speaks in the negative;
Murius Mersennus, and others, declare in the affirmative. The decision of the ques-
tion, however, depends on the definition we
give to the consonance. If by a con-
sonance we only understand two or more sounds
agreeable to the ear, the union is a con-
sonance; but if we include in the consonance
sounds of a different pitch, i.e. sounds less
or greater, they will be bound by such an act;
but a thing is only voidable which is done
by a person who ought not to have done it,
but who, nevertheless, cannot avoid it him-
self after it is done; though it may be by
some act, and not made void by his heir, &c.
2 Liti. Abr. 807.
VOLCANO, in natural history, a burning
mountain, or one that occasionally vomits
forth fire, flame, ashes, cinders, &c. Vol-
canoes are of two kinds, and have two
necessary connection with any other
mountains, but seem to have some with the
sea, as the relics of fishes, sea-weed, and
sometimes sea-water itself. Sir William
Hamilton observes in the Phil. Trans, for
1776, that "the operations of Vesuvius are
very capricious and uncertain, except that
the sea is always considerably and const-
antly when the sea is agitated, and the wind
blows from that quarter. Volcanic moun-
tains are of all heights; some, as that of
Tanase, so low as 430 feet; Vesuvius is
3800 feet high; and Etna, 11000. They in general
are very lofty spires; and the volcano itself is
frequently shaped like an inverted cone,
placed on a broader basis. This cone is
called the crater, or bowl, and through it the
lava generally passes, the springs at the
bottom, and sometimes in the middle
of the mountain. Sometimes the crater falls in, and
is effaced; sometimes, in extinguished volca-
noes, it is filled with water. Submarine vol-
canoes have been observed, and from some
al exert a power derived from the origin. Vol-
canic fires taking place at the bottom of the
ocean, would freely, by the expansive
force of the streams which are generated,
elevate those parts which were once at the
bottom of the ocean, and bring those which
were habitable earth. It is conjectured, that
subterraneous convulsions operated more
powerfully in the early ages of the world than
any other period; and indeed such an hy-
pothesis is supported by the most probable
reasoning, since we may well conceive that
at the first formation of the earth, much
heterogeneous matter would be included in
the different masses, which might produce
more frequent fermentations than at any after
periods, when these have been, if we may so
express it, purged off by frequent eruptions,
and in many parts, perhaps, rectified and
assimilated by slow and secret processes in
the bowels of the earth. But history was not
cultivated till a very late period, and the
most eventful ages of nature have passed
without record.
The force of subterraneous fires, or rather
of the steam which is generated by them,
is so great, that considerable rocks have
been raised, and thrown for distances of eight
miles. A stone was once taken from the
crater of that volcano twelve miles, and
told upon the marquis of Lauro's house at
Nola, which it set on fire. One also, which
measured twelve feet in height and forty-five
feet in circumference, was carried, in 1707,' by
the projectile force of the steam, a quarter of
a mile from the crater. In an eruption of
Etna, a stone, fifteen feet long, was ejected
from the crater in the distance of a mile, and
buried itself eight feet deep in the ground.
A volcano broke forth in Peru in 1600,
accompanied with an earthquake, and the
sand and ashes which were ejected covered the
fields ninety miles one way, and one hundred
and twenty another. Dreadful thunders
and lightning were heard and seen for upwards
of ninety miles round Arapappu during this
eruption, which seemed to denote some con-
nection between the electric matter and these
volcanic fires; and this fact is strongly con-
firmed by the very accurate observations
of Sir William Hamilton, which we shall after-
wards have occasion to notice more at large.
Sir William Hamilton measured these
many volcanoes, consist of lava, either entire
or decomposed, nearly as low as the level of
the sea; but they finally rest either on gran-
ite, as in Peru, or schist, as the extin-
guished volcanoes in Spain and Bohemia,
or on limestone, as those of Silesia, mount Ve-
suvius, &c. No one is found in these
mountains, except that of iron, of which
lava contains from twenty to twenty-five parts in
the hundred, and some other fragments of the
ores of copper, antimony, and arsenic.
Vesuvius ejected, from the year 1779 to
1783, 369,658,101 cubic feet of matter of
different kinds; we must therefore conclude
that Vesuvius to the distance of these several
miles below the level of the sea; and iron makes
it one-fourth to one-fifth of these ejections,
we may infer that the internal parts of the
earth abound with such metal.
The origin of these subterraneous fires is
not easily explained. Iron-fillings mixed with
Volcanic sulphur, and the whole massened with water into it, will swiftly become hot, and if the quantity is considerable, will throw out a blue flame. It is a mixture of this kind which is used for making an artificial earthquake; for such a quantity of inflammable gases is the secret of the phenomenon of an earthquake. M. Lenormy seems to have been the first person who illustrated, in this manner, the origin of volcanic fires and earthquakes. He mixed twenty-five pounds of iron filings with an equal weight of sulphur, and having made them into a paste, with the addition of water, he put them into a pot, covered them with a cloth, and buried them a foot under ground. In about eight or nine hours the earth swelled, became warm, and cracked, and hot sulphureous vapours were perceived. Now large beds of mottled pyrites, sulphuret of iron, are known to exist in different parts of the earth; the only difficulty which attends this explanation of the origin of volcanoes, as well as of earthquakes, is, that there is no inflammation necessary for the production of actual flame. It is well known, however, that sulphuret of iron, when moistened, acquires heat; and if we suppose it to have been in contact with black and petroleum, we may suppose the flame to arise, as we see it produced by art, from the desiccation of the former substance, and its mixture with mineral oil. Many minerals, when heated, afford oxygen gas, a very active inflammable gas; in the case of that produced in the volcano, a remnant of that, at the foot of which the Giant Causeway is situated, he presumes cannot be less than five or six hundred feet perpendicular above the level of the Atlantic ocean, and yet composed entirely of lava; the same appearances extend towards the south upwards of twenty miles.

The most remarkable volcanoes in Europe are Etna and Vesuvius; and as these are not too far distant, we have the most accurate descriptions of them from travellers of the first talents and reputation.

Etna, which is the most striking object in Sicily, and indeed one of the most magnificent productions of nature, rises from an immense base, and is equally on all sides to its summit. The ascent up each side is computed at about thirty miles, and the circumference of its base, at one hundred and thirty-three; but as it has never been measured with any great degree of accuracy, its dimensions are but imperfectly known.

The whole mountain is divided into three distinct regions, called La Region Culta, or Piedmontese, the fertile region; La Regione Sylvia, or Nemorosa, the woody region; and La Region. Desertæ, or and seats, the barren region. These differ as materially both in climate and production as the three zones of the earth, and perhaps with equal propriety might have been styled the torrid, the temperate, and the frigid zone.

The first region of Etna surrounds the base of the mountain, and constitutes the most fertile country in the world on all sides of it, to the extent of fourteen or fifteen miles, which begins. It is composed almost entirely of lava, which, in time, becomes the most fertile of all soils; but the roads, which are entirely over old lava, now converted into orchard, vineyards, and corn-fields, are execrable. The lava, which form this region, arise from a number of beautiful little mountains, every one of which seems to have immense declivities of Etna. These are all either of the oval or hemispherical figure, and are generally covered with beautiful trees, and the most luxuriant verdure. The formation of them is one to the internal fires of Etna, which, raging for a vent, at so vast a distance from the great crater, that it cannot possibly be carried to the height of twelve or thirteen thousand feet, which is probably the height of the Summit of Etna, must necessarily be discharged at some other orifice. After shewing the mountain, and its neighbourhood, for some time, at length the fire bursts open its side, and this is called an eruption. At first it emits only a thick smoke and showers of ashes. These are followed by red-hot stones, and rocks of a great size, which are thrown to an immense height in the air. These stones, together with the quantities of ashes discharged at the same time, form those mountains, which cover the defects of the crater, and its neighbourhood, for some time, at length the fire bursts open its side, and this is called an eruption. After the formation of the new mountain, the lava commonly bursts out from its lower side, and, sweeping every thing before it, is generally terminated by a fire-sea, which issues from the side of the mountain, without these attending circumstances, which are commonly the case with the eruptions of Vesuvius. It was at this time, that the first appearance of the lava appeared.

Many striking remains of the great eruption in 1669 are still to be seen, and will long continue as memorials of that dreadful event which overwhelmed Catania, and all the adjacent country. Tremendous earthquakes shook the island, and monstrous hollows were heard in the mountains. During some weeks, the sun ceased to appear, and the day seemed changed into night. Borelli, who was a witness to these terrible phenomena, says, that at length a torrent, twelve miles in length, was opened in the country, in some places of which, when they threw down stones, they could not hear them reach the bottom. Burning rocks, sixty palms in length, weighing to the value of a mile, and lesser stones were carried thirteen miles. After the most violent struggles, and a shaking of the whole island, an immense torrent of lava washed from the rent, and sprung up into the air to the height of sixty palms, whence it poured down the mountain, and overwhelmed every object in its way in one tremendous ruin.

This destructive torrent, which burst from the side of the mountain, covered the country with a vast sea of molten rock, and rolled with ruthless impetuosity against the beautiful mountain of Montpelleri, and pierced into the ground to a considerable depth; then dividing and surrounding the mountain, it
VOLOCANO.

The eruption of Vesuvius, which was a witness in the year 1717, and the reader will find his narrative in the first volume of Dr. Goldsmith's History of the Earth and Animated Nature, p. 94. Mr. Wollaston's short, and philosophical account of this formidable phenomenon, a volcanic explosion, is that with which Sir William Hamilton has favoured the public, in describing the dreadful eruption of that mountain in June 1794, and this we shall endeavour to give, as nearly as possible, in his own words.

Sir William begins his narrative with remarking that the frequent slight eruptions of lava for some years past had issued near the summit, and rain in small channels in different directions down the flanks of the mountain, and from running in covered channels, had often an appearance as if they came immediately out of the crater; but Vesuvius had not sufficient force to reach the cultivated parts at the foot of the mountain. In the year 1779, the whole quantity of the lava in fusion having been at once thrown up with violence from the crater of Vesuvius, and a great part of it falling and cooling on its cone, added much to the solidity of the walls of this huge natural chimney, and had not of late years allowed of a sufficient discharge of lava to calm that fermentation, which by the subterraneous noises heard at times, and by the explosions of scarce ashes, was known to exist within the bowels of the volcano. The eruptions, therefore, of late years, before this last, were simply from the lava having boiled over the crater; and though, indeed, after a small earthquake and storm, it is not quite to confine it, and oblige it to rise and overflow. The mountain had been remarkably quiet for seven months before the late eruption, nor did the usual vapour issue from its crater, but at times a light cloud of smoke that floated in the air in the shape of little trees. It was remarked by Father Antonio di Petrizzi, a Capuchin friar, (who printed an account of the late eruption,) from his convent close to the unfortunate town of Torre del Greco, that for some days preceding this eruption, a thick vapour was seen to surround the mountain, about a quarter of a mile beneath its crater, and it was observed by him and others at the same time that both the sun and the moon had often an unusual reddish cast.

The water of the great fountain at Torre del Greco began to decrease some days before the eruption, so that the wheels of a mill were brought to a standstill, and, of course, very slowly; it was necessary in all the other wells of the town and its neighbourhood to lengthen the ropes daily, in order to reach the water; and some of the wells became dry. Although most of the inhabitants were sensible of this phenomenon, not one of them seems to have been sensible of the true cause. Eight days after the eruption, a man and two boys being in a vineyard along the crater of Vesuvius (and precisely on the spot where one of the new mouths opened, whence the principal current of lava that destroyed the town issued,) were much alarmed by a sudden puff of smoke which issued from the earth close to them, and was attended with a slight explosion.

Had this circumstance, with that of the subterraneous noises heard at Resina for two days before the eruption (with the additional one of the decrease of water in the wells,) been observed at the time, it would have required no great foresight to have been certain that an eruption of the volcano was near at hand, and that its force was directed particularly towards that part of the mountain.

On the 12th of June 1794, in the morning, there was a violent fall of rain, and soon after the inhabitants of Resina, situated directly over the antient town of Herculaneum, were sensible of a rumbling subterraneous noise, which was quite heard at Naples.

From the month of January to the month of May, the atmosphere had been generally calm, and there was continued dry weather. In the month of May there was a little rain, but the weather was unusually sultry. For some days wrought by that rain, the duke della Torre, a learned and ingenious nobleman, who published two letters upon the subject of the eruption, observed by his thermometers, that the atmosphere was charged with heat, and had an eruption with an earthquake and storm immediately followed, and it continued for several days during the eruption.

About eleven o'clock on the night of the 12th of June, the inhabitants of Naples were all sensible of a violent shock of an earth quake; the undulatory motion was evidently from east to west, and appeared to have lasted near half a minute. The sky, which had been quite clear, was soon after covered with black clouds. The inhabitants of the towns and villages, which are very numerous round Mount Vesuvius, were very much terrified, and most of them thought that an earthquake was more sensible, and say, that the shock at first was from the bottom upwards, after which followed the undulation from east to west. This earthquake extended all over the Campagna Felice, and the royal palace at Caserta, which is fifteen miles from Naples, and one of the most magnificent and solid buildings in Europe (the walls being eighteen feet thick,) was shaken in such a manner as to cause great alarm, and all the chamber bells rang. It was likewise much felt at Beneventi, about thirty miles from Naples; and at Arzano in Puglia, which is at a much greater distance; both these towns, indeed, have been often afflicted with earthquakes.

On Sunday the 15th of June, soon after ten o'clock at night, another shock of an earthquake was felt at Naples, but did not appear to be so violent as that of the day before. It was at the same moment a fountain of bright fire, attended with a very black smoke and loud report, was seen to issue, and to rise to a great height, from about the middle of the cone of Vesuvius. Soon after the same kind broke out at some little distance lower down; then, as is supposed, by the blowing up of a covered channel full of red-hot lava, it had the appearance as if the lava had taken on its course up the steep sides of the volcano. Fresh fountains succeeded one another hastily, and all in a direct line, tending, for about a mile and a half, down towards the towns of Resina and Torre del Greco. Sir William Hamilton could count fifteen of them, but believes there were others obscured by the smoke. It seems probable, that all these fountains of fire, from their being in such an exact line, proceeded from the same point on the flanks of the mountain, and that the lava and other volcanic matter forced its way out of the widest parts of the crack, and formed there the little mountains and craters that have been described, or which are to be seen in that place. It is impossible that any words can give an idea of the blazing scene, or of the horrid noises that attended this great operation of nature. It was a mixture of the loudest thunder, with incessant reports, like those from a numerous heavy artillery, accompanied by a continued hollow murmur, like that of the roaring of the ocean during a violent storm; and, added to these was another blowing of a different kind, that of a large flight of sky-rockets, or rather like that which is produced by the action of the enormous belows on the furnace of the Carron iron-foundry in Scotland. The frequent falling of the huge stones and scorches, which were thrown up to an incredible height from some of the new mouths, (one of which, having been since measured by the able Tata, was found to be ten feet high, and thirty-five inches in breadth,) was so near the tops of the houses to the concussion of the earth and air. As the lava did not appear to have yet a sufficient vent, and it was now evident that the earthquakes already felt had been occasioned by the air and fiery matter combined within the
Volcano.

Towers of the mountain, and probably at no small depth, considering the extent of those earthquakes, sir William recommended to the company that he and his friends, with their sick, should begin that day to ascend, rather to go and view the mountain at some greater distance, and in the open air, than to remain in the house, which was on the sea-side, and in the part of Naples which is nearest and most exposed to Vesuvius. They accordingly proceeded to Posillipo, and viewed the conflagration, now become still more considerable, from the sea-side under that mountain; but whether from the eruption having increased or from the long reports of the volcanic explosions being repeated by the mountain behind them, the noise was much louder and more alarming than that they had heard in their first position, at least a mile nearer to Vesuvius.

After some time, about two o'clock in the morning of the 16th, it was observed that the lavas ran in abundance, freely, and with great velocity, having made a considerable progress towards Resina, the town which it first attacked; and that the fiery vortices which had been confined now free vent through many parts of a crack of more than a mile and a half in length, as was evident from the quantity of inflamed matter and black smoke, which continued to issue from the sea-side. Our author therefore concluded that at Naples all danger from earthquakes, which had been its greatest apprehension, was totally removed, and he returned to his former station at St. Lucia near the city.

During all this time there was not the smallest appearance of fire or smoke from the crater on the summit of Vesuvius; but the black smoke and ashes issuing continually from so many new mouths or craters, formed an enormous and dense body of clouds over the whole mountain, and began to give signs of being replete with the electric fluid, by exhibiting flashes of that sort of zig-zag lightning, which in the volcanic language of the country is called ferilli, and which is the constant attendant on the most violent eruptions.

Sir William Hamilton proceeds to remark, that during a thirty years residence at Naples, and during which time he had been witness to many eruptions of Vesuvius, he never before saw the cloud of smoke replete with the electric fire, excepting in the two eruptions of 1794, and in that of 1779. The electric fire, in the year 1779, which played constantly within the enormous black cloud over the crater of Vesuvius, and seldom quitted it, was exactly similar to that which is produced, on a very small scale, by the conductor of an electrical machine communicating with an insulated plate of glass, thinly spread over with metallic filings, &c. when the electric matter continues to play over it in zig-zag lines without quitting the surface. He was not sensible of any noise attending that operation in 1779; whereas the discharge of the electrical matter from the volcanic clouds during this eruption, and particularly on the second and third days, caused explosions like those of the loudest thunder; and indeed the storm raised evidently by the sole power of the volcano, resembled in every respect all other thunder-storms, including lightning, and destroying every thing in its course. The house of the marquis of Berio at St. Lucio, situated at the foot of Vesuvius, during one of these volcanic storms, was struck with lightning, which having shattered many doors and windows, and damaged the furniture, left for some time a strong smell of sulphur in the rooms it passed through; and these gigantic volcanic clouds, besides the lightning, the author adds, he had, with many others, both during this eruption, and in 1779, seen balls of fire issue, and some of a considerable magnitude, which bursting in the air, passed as from the ducal air-balloons in fireworks; the electric fire, as it came out, having the appearance of the serpents with those firework-balloons are often filled. The day before this, the 15th, there was in the crater danger from the volcanic clouds, two small balls of fire, joined together by a small link like a chain-shot, fell close to his casino at Posillipo; they separated, and one fell in the vineyard, at the house, and the other in the sea; the latter so close to it that he heard the splash in the water. The abbe Tata, in his printed account of this eruption, mentions an enormous ball of fire which flew out of the crater of Vesuvius while he was at the edge of it, and which burst in the air at some distance from the mountain, soon after which he heard a noise like the fall of a number of stones, or of a heavy shower of hail.

About four o'clock in the morning of the 16th, the crater of Vesuvius began to show signs of being replete, by some black smoke issuing out of it; and at day-break another body of smoke, tinged with red, issued from an opening near the crater. On the other side of the mountain, and opposite the town of Ottiano, it became evident that a new mouth had opened, from which a considerable stream of lava issued, and ran with great velocity through a wood, which it burnt; and having run about three miles in a few hours, it stopped before it arrived at the vineyard and cultivated lands. The crater, and all the conical part of Vesuvius, were soon involved in clouds and darkness, and remained so for several days; but above these clouds, by the heat of that great height, from columns of smoke were seen from the crater, rising furiously still higher, until the whole mass remained in the usual form of a pine-tree; and in that gigantic mass of heavy clouds the fire, or volcanic lightning, was frequently visible, even in the day-time.

About five o'clock in the morning of the 16th, the lava which had first broken out from the several new mouths on the south side of the mountain, had wandered into the sea, and was running into it, having overwhelmed, burnt, and destroyed, the greatest part of Torre del Greco, the principal stream of lava having taken its course through the very centre of the town.

Soon after the beginning of this eruption, ashes fell thick on the foot of the mountain, all the way from Portici to Torre del Greco; and what is remarkable, although there were at that time any clouds in the air, except those of smoke from the mountain, the ashes were wet, and accompanied with large drops of water, which to the taste were very salt; the road, which was paved, was as wet as if there had been a heavy shower of rain. These ashes were black and coarse, like the sand of the sea-shore; whereas those which fell there and at Naples some days after, were of a light-grey colour, and as fine as Spanish snuff, or powdered bark. They consisted of ashes which lay on the ground, exposed to the burning sun, had a coat of the whitest powder on their surface, which to the taste was extremely salt and pungent.

By the time that the lava had reached the sea, between five and six o'clock in the morning of the 16th, Vesuvius was so completely involved in darkness, that the violent operation of nature which was going on there could no longer be discerned, and so it remained for several days; but the dreadful noise, and the red tinge on the clouds over the top of the mountain, were evident signs of the activity of the fire underneath. The lava ran but slowly to Torre del Greco after it had reached the sea; and on the 17th of June in the morning, its course was stopped; excepting that at some a little relapse of red fire issued from under the smoking scoria into the sea, and created all this time a great quantity of large scoriae, which were dashed on to the surface of the body of the lava into the sea, discovering that it was red-hot under that surface. Even to the latter end of August, the summit of the thick crust of lava that covered the tower retained its red heat.

The breadth of the lava that ran into the sea, and formed a new promontory there, after having destroyed the greatest part of the town of Torre del Greco, having been exactly measured by the duke deli Torre, is 1204 English feet. Its height above the sea is twelve feet, and as many feet under water; so that its whole height is twenty-four feet; it extends into the sea 606 feet. The sea-water was boiling as in a cauldron, where it washed the foot of this new-formed promontory.

The rapid progress of the lava, however, was such, after it had altered its course from Resina, which town it first threatened, and had joined a fresh lava that issued from one of the mouths of the mountain, that in a few days, it was five or six miles from the town, that it ran like a torrent over the town of Torre del Greco, allowing the unfortunate inhabitants scarcely time to save their lives. Their goods and effects were entirely absorbed, and several of the inhabitants, whose houses had been surrounded with lava while they remained in them, escaped from them, and saved their lives the following day, by coming out of the tops of their houses, and walking over the scoria on the surface of the red-hot lava.

The lava over the cathedral, and in other parts of the town, is said to be upwards of forty feet in thickness; the general height of the lava, during its whole course, was between twelve and fourteen feet, and in some parts not less than a mile, in breadth.

On Wednesday June 18, the wind having for a short space of time cleared away the thick cloud from the top of Vesuvius, it was now discovered that a great part of its crater was filled by a heavy column of smoke, and violently thrown out of it, and that one of the west side opposite to Naples, had fallen; in which it probably did about four o'clock in the morning of that day, as a violent shock of an earthquake was felt at that moment at Resina, at some parts of the foot of the volcano. The clouds
of smoke, mixed with the ashes, were of such a density as to appear to have the greatest difficulty in forcing their passage out of the now widely-extended mouth of Vesuvius, which, since the top fell in, is described as not much short of two miles in circumference. One cloud descended on another, and succeeded one another incessantly, in a few hours such a gigantic and elevated column of the darkest hue over the mountain, as seemed to threaten Naples with immediate destruction: with a quadrat the elevation of a mass of clouds of which certainly, however it may contradict our idea of the extension of our atmosphere, rose many miles above the mountain, it appeared like a molehill, although the depth and height of Vesuvius, from the level of the sea, is more than three thousand six hundred feet. The abbe Braccini, as appears in his printed account of the eruption of mount Vesuvius in 1831, states that he ascended an elevation of a mass of clouds of the same nature, which was formed over Vesuvius during that great eruption, and found it to exceed thirty miles in height. Dr. Scotti, in his printed account of this eruption says, that the height of the threatening cloud of smoke and ashes, measured from Naples, was found to be of an elevation of thirty degrees.

The hable curiosity of our author induced him to go upon mount Vesuvius, as soon as it was possible with any degree of prudence, which was not until the 30th of June, and even then it was attended with some risk. The crater of Vesuvius, except at short intervals, had been continually obscured by small clouds from the 18th; and was so on that day, with frequent flashes of lightning playing in those clouds, and attended as usual with a noise like thunder; and the fine ashes were still falling on Vesuvius, but still more on the mountain of Somma. Sir William went up the usual way by Resina, and observed, in his way through that village, that many of the stones of the pavement had been loosened, and were deranged by the earthquakes, particularly of that of the 18th, which attended the falling in of the crater of the volcano, and which had been so violent as to throw many people down, and obliged all the inhabitants of Resina to quit their houses hastily, to which they did not dare to return for two days. The leaves of all the vines were burnt by the ashes that had fallen on them; and many of the vines themselves were buried under the ashes, and great branches of the trees that supported them had been torn off by their weight. In short, nothing but ruin and desolation was to be seen. The ashes at the foot of the mountain were about ten or twelve inches thick on the surface of the earth; but in proportion as he ascended, their thickness increased to several feet, not less than nine or ten in some spots. On the surface of the old rugged lavas, which before was almost impracticable, was now become a perfect plain, over which he walked with the greatest ease. The ashes were of a light-grey colour, and exceedingly fine, so that by the footsteps being marked on them as on snow, he learnt that three small parties had been up before him. He saw likewise the track of a fox, which appeared to have been quite bewildered by the many turns he had made. Even the traces of lizards and other little animals, and of insects, were visible on these fine ashes. Sir William and his companion ascended to the spot whence the lava of the 13th first issued, and followed the course of it, which was still very hot (although covered with such a thick coat of ashes) quite down to the sea at Torre del Greco, which is more than five miles. It was not possible to go up to the great crater of Vesuvius, nor had anyone attempted it. The horrid chasms that existed from the spot where the late eruptions first took place, in a straight line for near two miles towards the sea, were at once perceived. They formed valleys more than two hundred feet deep, and from half a mile to a mile wide; and where the fountains of fiery matter issued during the eruption, were little mountains with deep craters. Ten thousand men, in as many years, could not have made such an alteration on the face of Vesuvius. Except the exhalations of sulphurous vapours, which broke out from different spots of the line above-mentioned, and tinged the surface of the ashes and scoria in those parts with either a deep or pale yellow, or a reddish ochre-colour, or a bright white, and in some parts with a deep green and azure blue (so that the whole together had the effect of an iris), all had the appearance of a sandy desert. Our adventurers then went on the top of seven of the most considerable of the new-formed mountains, and looked into their craters, which on some of them appeared to be little short of half a mile in circumference; and although the exterior perpendicular height of them did not exceed two hundred feet, the depth of their inverted cone within was three times as great. It would not have been possible to have breathed at all, near these mountains, near their craters, if they had not taken the precaution of tying a double handkerchief over their mouths and nostrils; and even with that precaution they could not resist long the flames of the sulphurous acid and were so exceedingly penetrating, and of such a suffocating quality. They found in one a double crater, like two tunnals joined together; and in all there were some little smoke and deposition of salts and sulphurs, of the various colours above-mentioned, as is commonly seen adhering to the inner walls of the principal crater of Vesuvius.

Two or three days after they had been there, one of the new mouths into which they had looked, suddenly made a great explosion of stones, smoke, and ashes, which would certainly have proved fatal to any person who might unfortunately have been present at the time of the event, for they were on the mountain, two whistlings, exactly like those that form water-spouts at sea, made their appearance; and one of them, which was very near, made a strange rushing noise; and having taken up a great quantity of the lavas, formed them into an elevated spiral column, which, with whirling motion and great rapidity, was carried towards the mountain of Somma, where it broke and was dispersed. One of our author's servants, employed in collecting sulphur, or sal ammoniac, which is carried on the near mountains, in which they at one time, as they are called, with the hot vapours out of the fresh lava), found to his great surprise, an exceeding cold wind from a fissure very near the hot fumarole, usual in vinegar. In a vineyard not in the same line with the new-formed mountains just described, but in a right line from them, at the distance of little more than a mile from Torre del Greco, they found three or more of these new-formed mountains with craters, out of which the lava flowed; and by uniting with the streams that came from the higher mouths, and adding to their heat and fluidity, enabled the whole to make a rapid progress over the unfortunate town.

In the town of Somma, our author found four churches and about seventy houses without roofs, and full of ashes. The great damage on that side of the mountain, by the fall of the ashes and the torrents, happened on the 18th, 19th, 20th, and 25th of June, and on the 12th of July. The 18th, the ashes fell so thick at Somma, that unless a person kept in motion, he was soon fixed to the ground by them. This fall of ashes was accompanied also by loud reports, and frequent flashes of the volcanic lightning so that, surronded by so many horrors, it was impossible for the inhabitants to remain in the town, and they all fled; the darkness was so great, although it was mid-day, that even with the help of torches it was scarcely possible to keep in the high road. On the 16th of July, signor Giuseppe Sacco went up to the crater; and, according to his account, which is printed at Naples, the crater is now of an incredible size. The supposes (not having been able to measure it) of about a mile and a half in circumference; the inside, as usual, in the shape of an inverted cone, the inner walls of which on the eastern side, and on the western side of the crater, which is lower, the descent was practicable, and Sacco with some of his companions actually went down one hundred and seventy-six palms; from which spot having lowered a cord with a stone tied to it, they found the whole depth of the crater to be about five hundred palms. Such observations, however, on the crater of Vesuvius, are of little consequence, as both its form and apparent depth are subject to great alterations from day to day.

On the 22d of July, one of the new craters, which is the nearest to the town of Torre del Greco, threw up both fire and smoke; which circumstance, added to that of the lava's retaining its heat much longer than usual, which was also the fact, that there was still some fermentation under that part of the volcano. The lava in cooling often cracks, and causes a loud explosion, just as the ice does in the glaciers in Switzerland; such reports were frequently heard at the time at the Torre del Greco; and a vapour was seen to
issue from the body of the lava, and taking fire in the air, fall like those meteors vulgarly called falling stars.

The archbishop of Taranto, in a letter to Naples, and dated from that city the 18th of June, observes: "We are involved in a thick cloud of minute volcanic ashes, and we imagine that the mass of that cloud was deposited either at mount Etna or of Stromboli. The bishop did not suspect their having proceeded from Vesuvius, which is about two hundred and fifty miles from Taranto. Ashes also fell at the late eruption, at the very extremity of the province of Loccro, which is still farther off; and at Martino, near Taranto, a house was struck and much damaged by the lightning from one of the clouds. In the course of the great eruption of Vesuvius in 1631, mention is made of the exten-

sive progress of the ashes from Vesuvius; and of the damage done by the fertil, or volcanic lightning, which attended them in their course.

Our author in this place mentions a very extraordinary circumstance, which happened near Sienna, in the Tuscan state, about eighteen hours after the commencement of the late eruption of Vesuvius on the 15th of June, which adds, that phenomenon must not be related to the eruption; it was communicated to him, in the following words, by the earl of Bristol, bishop of Derry, in a letter dated from Sienna, July 12, 1794: "In the midst of a most violent thunder-storm, about a dozen stones of various weights and dimensions fell at the feet of different people, men, women, and children; the stones are of a quality not found in any part of the Siennese territory; they fell about eighteen hours after the enormous eruption of Vesuvius, which circumstance leaves a choice of difficulties in the solution of this extraordinary phenomenon: either these stones have been generated in this igneous mass of clouds, which produced such unusual thunder; or, which is equally incredible, they were thrown off from Vesuvius at a distance of at least two hundred and fifty miles; judge then of its paradox." One of the largest stones, when entire, weighed upwards of five pounds. The owner of this stone, a man of business, and ascendant to have fallen from the cloud near Sienna, was evidently fresh-vitrified, and black, with indubitable signs of having passed through an extreme heat; when broken, the inside was found of a light-grey colour mixed with black spots, and some shining particles, supposed to be pyrites. Stones of the same nature, at least as far as the eye can judge of them, are frequently found on mount Vesuvius; and it is probable he might find, with the same vitrified coat on them, the question would be decided in favour of Vesuvius; unless it could be proved that there had been, about the time of the fall of these stones to the Siennese territory, some nearer opening of the earth, attended with an emission of volcanic matter; which might very possibly happen, as the mountain of Kadefon, within fifty miles of Sienna, is so near that place. The celebrated father Ambrogio Spinola, professor in the university of Siena, has printed there a dissertation upon this extraordinary phenomenon: and, it is said, has decided that those stones were generated in the air independently of volcanic assistance. See Meteoric Stones.

Until after the 7th of July, when the large cloud broke over Vesuvius, and formed a tremendous torrent of mud, which took its course across the great road between Torre del Greco and the Torre dell' Aumunziata, and destroyed many villages, the eruption could not be said to have finished, although the force of it was over the 22d of June. The power of attraction in mountains is well known; but whether the attractive power of a volcanic eruption is greater than that of any other mountain, is not known. During this eruption, however, it appeared that every watery cloud was evidently attracted by Vesuvius, and the sudden dissolution of these clouds left marks of their destructive power on the face of the country all round the basis of the volcano. After the mouth of Vesuvius was enlarged, our author says he has seen a great cloud passing over it, which not only was not attracted, but even sucked in, and disappeared in the atmosphere.

After every violent eruption of mount Vesuvius, we read of damage done by a mephitic vapour; which proceeding from under the ancient lavas, insinuates itself into low places, such as the cellars and wells of the houses standing at the foot of the volcano. After the eruption many years, there were several instances, as this, of people, going into their cellars at Portici, and other parts of that neighbourhood, having been struck down by the vapour, and who would have expired if they had not been hastily removed. These occasional vapours, or mepote, are of the same quality as that permanent one in the Grotte del Cane, near the lake of Agerano, and which has been proved to consist chiefly of fixed air. The vapours which, in the volcanic language of Naples, are called funamori, are of another nature, and issue from spots all over the fresh and hot lavas while they are cooling; they are sulphureous, and are observed that often the birds which are flying over them are overpowered, and fall down dead.

The interior of a volcano, that immense treasury of devastation, must undoubtedly be an object of philosophical curiosity: yet when we consider the attempt, that the incompact state of the materials, by affording no proper support, may harass the incipient adventurer into the burning abyss; that the mephitic vapours may produce instantaneous suffocation; and that a sudden explosion may overwhelm him with destruction; we cannot wonder that so few have engaged in an exploit so replete with danger. We should have remained ignorant of this state of this immense territory of 1767, if there had not the spirit or tenacity of eight Frenchmen, in the year 1801, enabled them successfully to explore this cavern of destruction. The mouth, or upper base, of the crater of Vesuvius, which is a little inclined to its axis, is represented by these travellers as 372 feet in circumference. After walking round the aperture of the volcano, in order to choose the most commodious part for descending, M. Donnelle, a jurist, ambassador, and M. Wickar, a painter, first descended, with any accident at the determined point; but, however, they found themselves stopped by an excavation of 50 feet, which it was neces-

sary to pass. Finding it impossible to obtain a fixed support on ashes so movable, and being convinced that the friction of ropes would have destroyed both the proper support and the neighbouring masses, they resolved to return. Some stones at the same moment rolled from the summit, and occasioned an agitation as they passed; the ground shook under their feet, and they had scarcely quitted it when it disappeared and fell in.

After walking once more round the mouth of the crater, they discovered at length a long eddication, smooth though steep, which appeared to conduct to the focus. When they had proceeded half-way, amidst a torrent of ashes which rolled down along with them, they found means to fix themselves on the edge of the precipice, twelve feet in height, which it was necessary to pass. With one of the Lazarus, however, they plunged down this precipice; and found themselves on the brink of another, which, however, not being quite so high, they passed with more ease. At length, amidst showers of falling lava, ashes, and stones, they reached the bottom of the crater.

They found the immense furnace still smoking in several places; near the bottom of the crater, which from above appeared so perfectly smooth, was found on the contrary, when they reached it, exceedingly rough and uneven. They passed over lava very porous, in general hard, but in some places, and particularly where they entered, still soft, so as even to yield under their feet. The spectacle, however, which most attracted them was the spiracles; which either at the bottom or interior sides, suffer the vapours to escape. These vapours, however, did not appear of a noxious quality. In traversing the crater they perceived a focus half-covered by a large mass of pumice stone, and which from its whole circumference emitted a strong heat. Reaumur's thermometer, on the summit of Vesuvius, stood at twelve degrees; in the crater it rose to sixteen; placed at one of the spiracles it indicated forty-four, at another twenty-two; and at the entrance of the Krater it never rose higher than twenty-two degrees.

The volcanic productions in the crater were large, exceedingly porous, and reduced by the fire in some parts. It was of a dark-brown colour in general; and in some places reddish, with a very little white. The substances nearest the spiracles were covered or impregnated with sulphur, which sometimes, in cavities of the rock, escaped. Some basaltic lava was also found; but in a small quantity. The burning focus produced the same results.

On the north side of the crater there were two large fissures, one of which was twenty feet in depth, the other fifteen. They were shaped like an inverted cone, and the matter with which they were covered was similar to the rest of the surface, but they emitted neither smoke nor heat.

The ascent of our adventurers was accomplis

hished with more difficulty, though perhaps with less danger, than the descent. It also occupied a greater space of time; for they could only ascend one at a time after considerable intervals, for fear of being swallowed under torrents of dust and volcanic matters, when who immediately suffered.
brown; the back, scapulars, and wings, crossed with broad bars of white and black; the rump is white; the tail consists of only ten feathers, white marked with black, in form of a crescent, the horns pointing toward the end of the feathers. The legs are short and black, the toes are closely united at the bottom to the middle toe. See Plate Nat. Hist. fig. 413.

According to Linnaeus, it takes its name from its note, which has a sound similar to the word; or it may be derived from the French, burophe, or "crested." It breeds in hollow trees, and lays two ash-coloured eggs: it feeds on insects, which it picks out of or- dure of all kinds. Dr. Pallas affirms, that it breeds in preference in putrid carcasses; and that he had seen it as a pet of a lady of an uninhabited house, in the suburbs of Tarzisyn. Ovid says that Tereus was changed into this bird.

URANIA, a genus of the hexandria monogynia class and order of plants. There is no flowers of the corolla is two-petalled; acci- turine two-leaved; capsule two-celled, many-seeded. There is one species.

URANIUM, a mineral found in Saxony, partly in a pure and partly in a mixed state. There are two varieties of these; the first of a blackish colour, quite opaque, tolerably hard, and with a specific gravity of about 7.5. The second is distinguished by a finer black colour, with here and there a reddish cast; by a stronger lustre, not unlike that of pitch; by an inferior hardness; and by a shade of green, which tinges its black colour when it is reduced to powder.

This fossil was called pechblende; and min- eralogists, misled by the name, had taken it for an ore of zinc, till the celebrated Werner, convinced from his text, hardness, and specific gravity, that it was not a blende, placed it among the ores of iron. After- wards he suspected that it contained tung- sten; and this conjecture was seemingly confirmed by the experiments of some German mineralogists, published in the Miners' Jour- nal. But Klaproth, the most celebrated ana- lyst in Europe, examined this ore in 1789, and found that it consists chiefly of sulphur combined with a peculiar metal, to which he gave the name of uranium.

Uranium is of a dark-grey colour; inter- nally it is somewhat inclined to brown. Its malleability is unknown. Its hardness is about 6. It requires a stronger heat for fusion than manganese. Indeed Klaproth only obtained it in very small conglutinated metallic grains, forming all together a porous and spongy mass. Its specific gravity is 6.440.

When exposed for some time to a red heat, it suffers no change. By means of nitric acid, however, it may be converted into a yellow powder. This is the yellow oxide of uranium, which seems to be composed of about 50 parts of uranium and 44 of oxygen. This oxide is found native, mixed with the mineral above described. From the experiments of Proust we learn that this metal is capable of forming only two oxides, but no description of the protioxide has been published; and the ore is so scarce that it is not every chemist who can gratify his curiosity by an examination of uranium.

Uranium is capable of combining with sul-
U R E

The mineral from which Mr. Klapp-oth first obtained it is a native sulphur of potassium.

URANOSCIUS, star-gazer, a genus of fish of the order Jurellidae. The generic character is the head large, depressed, rough; mouth furnished with an internal cirrus; gill-ridges edged by a ciliated border; gill-membrane five-rayed.

Uranoscopus scaber, bearded star-gazer. The head of this fish is large, square, and covered by a strong bony case, roughened by an infinite number of small warts or protuberances: each side of this case is terminated above by two spines, the hindermost of which is the strongest, and covered by a skin: the under part has five spines smaller than those above: the mouth, which is wide, opens in an almost vertical direction: the tongue is thick, short, and roughened with numerous small teeth; near the interior tip of the lower jaw is a membranous process which terminates in a long cirrus or beard extending to some distance beyond the lips, which are themselves edged with smaller ones: the eyes are situated very near each other on the top of the head; the body is of a somewhat squarish form as far as the vent, and thence becomes cylindrical: it is covered with small scales, and marked near the back by a lateral line composed of small pores or points bending from the neck to the pectoral fins on each side, and thence in a straight line to the tail, on the back are two fins, of which the first is much shorter than the latter, and furnished with stronger spines; the pectoral fins are small; the tail of moderate size, and rounded at the end. The colour of the body is brown, with a whitish or silvery cast towards the abdomen; the head, pectoral fins, and tail, having a strong ferruginous cast, and the first dorsal fin being marked towards its kind part by a large black spot.

The star-gazer is an inhabitant of the Mediterranean and northern sea, chiefly frequenting the shallower parts near the shores, where it lies concealed in the mud, with the tip of the head alone exposed: in this situation it waves the beards of the lips, and particularly the long cirrus of the mouth, in various directions, like that of some fishes and marine insects which happen to be swimming near, and which mistaking these organs for worms, are instantly seized by their concealed enemy. The usual length of this fish is about twelve inches. It is in no esteem as an article of food, being generally considered as coarse and of an ill flavour: the gall was consequently considered as of peculiar efficacy in external disorders of the eyes. There are only two species, viz. the scaber and lipiscus.

UREA, the constituent and characteristic matter of urine, may be obtained by the following process: Evaporate by a gentle heat a quantity of human urine, voided six or eight hours after a meal, till it is reduced to a thick syrup. In this state, when put to cool, it concretes into a crystalline mass. Pour at different times upon this mass four times its weight of alcohol, and apply a gentle heat; a great part of the mass will be dissolved, and there will remain only a number of saline substances. Pour the alcohol solution into a retort, and distil by the heat of a sand-bath till the liquid, after boiling some time, is reduced to the consistency of a thick syrup. The whole of the alcohol is then now separated, and what remains in the retort crystallizes as it cools. These crystals consist of the substance known by the name of urea.

Urea, obtained in this manner, has the form of crystalline plates crossing each other in different directions. Its colour is yellowish white: it has a feebid smell, somewhat resembling that of garlic or arsenic; its taste is strong and acrid, resembling that of ammoniacal salts; it is very volatile and difficult to cut, and has a good deal of resemblance to thick honey. When exposed to the open air, it very soon attracts moisture, and is converted into a thick brown liquid. It is extremely soluble in water, with traces of its solution a considerable degree of cold is produced. Alcohol dissolves it with facility, but scarcely in so large a proportion as water. The alcohol solution yields crystals much more readily on evaporation than the solution in water.

When nitric acid is dropped into a concentrated solution of urea in water, a great number of bright pearl-coloured crystals are deposited, composed of urea and nitric acid. No other acid produces this singular effect.

The concentrated solution of urea in water is brown, but it becomes yellow when diluted with a large quantity of water. The infusion of mugwells gives it a yellowish-brown colour; but causes no precipitation; neither does the infusion of tan produce any precipitation.

When heat is applied to urea, it very soon melts, swells up, and evaporates with an inoffensively fetid smell. When distilled, there comes over first benzoic acid, then carbont of ammonia in crystals, some benzoin, and carbont of prussic acid and oil; and there remains behind a large residuum, composed of charcoal, muriat of ammonia, and muriat of soda. The distillation is accompanied with an almost insupportable acidish allaceous odour. Two hundred and eighty parts of urea yield by distillation 200 parts of carbont of ammonia, 10 parts of carbureted hydrogen gas, 7 parts of charcoal, and 68 parts of benzoic acid, muriatic acid, and carbont of soda. These last three ingredients Fourcroy and Vauquelin consider as foreign substances, separated from the urine by the alcohol at the same time with the urea. Hence it follows, that 100 parts of urea, when distilled, yield 92.057 carbont of ammonia 4.608 carbureted hydrogen gas 3.225 charcoal

99.856

Now 200 parts of carbont of ammonia, according to Fourcroy and Vauquelin, are composed of 80 ammonia, 80 carbont of aed gas, and 24 water. Hence it follows that 100 parts of urea are composed of 39.5 oxygen 32.5 azote 14.7 carbon 13.3 hydrogen

100.0

But it cannot certainly be doubted that the water which was found in the carbont of ammonia existed ready-formed in the urea before the distillation.

When the solution of urea in water is kept in a boiling heat, and new water is added as it evaporates, the urea is gradually decomposed, a very great quantity of carbonic acid is given off, and ammonium is discharged: this acid is at the same time acetic acid is formed, and some charcoal precipitates.

When a solution of urea in water is left to itself for some time, it is gradually decomposed. A froth collects on the surface, and bubbles arise in it which have a strong disagreeable smell, in which ammonium and acetic acid are distinguishable. The liquid contains a quantity of acetic acid. The decomposition is much more rapid if a little gelatin is added to the solution. In that case more ammonia is disengaged, and the proportion of acetic acid is not so great.

When the solution of urea is mixed with one-fourth of its weight of diluted sulphuric acid, no effervescence takes place; but, on the application of heat, a quantity of oil appears on the surface, which concretes upon cooling; the liquid which comes over into the receiver contains acetic acid, and a quantity of sulphat of ammonia. In the former, chemists disengage in the distillation. By repeated distillations, the whole of the urea is converted into acetic acid and ammonia.

When nitric acid is poured upon crystalized urea, a violent effervescence takes place, the mixture froths, assuming the form of a dark-red liquid, containing quantities of nitrous gas, azotic acid, and carbontic acid, are disengaged. When the effervescence is over, there remains only a concrete white matter, with some drops of reddish liquid. When heat is applied to this residuum, it detaches like nitrat of ammonia. Into a solution of urea, formed by its attracting moisture from the atmosphere, an equal quantity of nitric acid, of the specific gravity 1.460, diluted with twice its weight of water, was added; a gentle effervescence ensued:—a very small heat was applied, which supported the effervescence for two days. There was disengaged the first day a great quantity of carbontic acid gas, and the second day, carbontic acid gas; and last nitrous gas. At the same time with the nitrous gas the smell of the oxypurassic acid of Berthollet was perceptible. At the end of the second day, the matter in the retort, which became thick, took fire, and burnt with a violent explosion. The residuum contained traces of prussic acid and ammonia. The receiver contained a yellowish acid liquor, on the surface of which some drops of oil swam.

Muriatic acid dissolves urea, but does not alter it. Oxymuriatic acid is gas absorbed very rapidly by a diluted solution of urea; small whitish flakes appear, which become brown, and adhere to the sides of the vessel like a concrete oil. After a considerable quantity of oxymuriatic acid had been absorbed, the solution, left, continued to effervescence exceedingly slowly, and to emit carbontic acid and azotic gas. After this effervescence was over, the liquid contained muriat and carbont of ammonia.

Urea is dissolved very rapidly by a solution of potass or soda, and at the same time a quantity of ammonia is disengaged; the same
substance is digested when urea is treated with barytes, lime, or even magnesia. Hence it is evident, that this appearance must be ascribed to the muriate of ammonia, with which it is constantly mixed. When pure solid potash is triturated with urea, heat is produced, a great quantity of ammonia is digested, the mixture becomes brown, and a substance is deposited, having the appearance of an empyreumatic oil. One part of urea and two of potash, dissolved in four times its weight of water, when distilled, gives out a great quantity of ammoniacal water; the residue contains acetan and carbonate of potash.

When muriat of soda is dissolved in a solution of urea in water, it is obtained by evaporation, not in cubic crystals, its usual form, but in regular octahedrons. Muriat of ammonia, on the contrary, which crystallizes naturally in octahedrons, is converted into cubes by dissolving and crystallizing it in the solution of urea.

URELA, a genus of the monadelphia polyanthaceae comprising the corolla wherein consists of five oval, obtuse, coniculate petals, broader than the apex, and narrower at the base; the fruit is a round echinated capsule, with five angles, consisting of five cells, and five united valves; the seeds are solitary, roundish, and compressed. There are eight species.

URETERS. See Anatomy.

URETHRA. See Anatomy.

UREIC ACID. Uric or lithic acid was discovered by Scheele in 1776. It is the common constituent of urinary calculi, and exists also in human urine. That species of calculus which resembles wood in its color and appearance is composed entirely of this substance. It was called at first lithic acid; but this name, in consequence of the remarks made by Dr. Pearson on its impropriety, has been laid aside, and that of uric acid substituted in its place.

Uric acid in this state has a brown colour; it is hard, and crystallized in small scales. It has a bitter taste nor smell, is insoluble in cold water, but soluble in boiling water. The solution reddens vegetable liquids, especially the tincture of turmeric. A great part of the acid precipitates as the water cools. It combines readily with alkalies and earths; but the compound thus formed is altered by every other acid. Muratic acid has no action on it, neither has sulphuric acid while cold, but when assisted by heat it decomposes it entirely.

When triturated with potash or soda, it forms a saponaceous paste very soluble in water when there is an excess of alkali, but sparingly when the alkali is neutralized. The urt of potash or of soda is nearly tasteless.

The last is found crystallized, constituting gouty concretions. Ammonia does not dissolve uric acid, but it combines with it, and forms a salt not more soluble than the pure acid, and resembling it in its external characters. Neither does uric acid dissolve in liquefied water; the ammoniacal salts have not action whatever on it.

Nitric acid dissolves it readily; the solution is of a pink-colour, and has the property of tingling animal substances, the skin for instance, of the same colour. When this solution is boiled, a quantity of azotic gas, car-bonic acid gas, and of prussic acid, is digested. When oxymuratic acid gas is made to pass into water containing this acid suspended in it, the acid assumes a gelatinous appearance, then dissolves; carbonic acid gas is emitted, and the solution yields by evaporation muriat of ammonia, superoxal of ammnia, muriatic acid, and malic acid.

When uric acid is distilled, about a fourth of the acid passes over with a little altered, and is found in the receiver crystalized in plates; a few drops of thick oil make their appearance; 8/9 of the acid of concrete carbonat of ammonia, some prussiat of ammonia, some water, and carbonic acid, pass over, and the remainder in the retort charcoal, amounting to about 36/9 of the weight of the acid distilled.

These facts are sufficient to show us that uric acid is composed of carbon, azote, hydrogen, and oxygen; and that the proportion of the two last ingredients is much smaller than of the other two.

URINE. No animal substance has attracted more attention than this, both on account of its supposed connection with various diseases and its account of the singular products obtained from it. Human urine, when fresh, is a transparent liquid of a light amber-colour, an aromatic smell, and a disagreeable bitter taste. Its specific gravity varies, according to Mr. Cruikshank, from 1.005 to 1.033. When it cools, the aromatic smell leaves it, and is succeeded by another, well known by the name of urinous smell. This smell is succeeded in two or three days by another, which has a considerable resemblance to that of sour milk. This smell gradually disappears in its turn, and is succeeded by a flat alkaline colour.

Urine reddens paper stained with tannine, and with the juice of radishes, and therefore contains an acid.

If a solution of ammonia is poured into fresh urine, a white powder precipitates, which has the properties of phospat of lime.

The presence of a white substance in urine was first discovered by Scheele. If lime-water is poured into urine, phospat of lime precipitates in greater abundance than when ammonis is used; consequently urine contains phospat of lime. Thus we see that the phospat of lime is kept dissolved in urine by an excess of an acid, or it is in the state of super-phospat. This also was first discovered by Scheele. This substance is most abundant in the urine of the sick. Berchtollet has observed, that the urine of gouty people is less acid than that of people in perfect health. The average quantity of phospat of lime in healthy urine is, as Cruikshank has ascertained, about 30/90 of the weight of the urine.

If the phospat of lime precipitated from urine is examined, a little magnesia will be found mixed with it. Fourcroy and Vaquez have ascertained that this is owing to a little phospat of magnesium which urine contains, and which is decomposed by the alkali or lime employed to precipitate the phospat of lime.

Proust informs us that carbonic acid exists in urine, and that it is kept dissolved, giving rise to the deposition of carbonic acid. If the urine is evaporated, the carbonic acid is precipitated, forming a crystalline carbonate of lime. However, we must conclude that urine contains carbonate of lime; a very extraordinary fact, to which we reflect that super-phospat of lime is also present.

When fresh urine cools, it often lets fall a brick-coloured precipitate, which Scheele first ascertained to be crystals of uric acid. All urine contains this acid; even when it is perfectly acid, and precipitated again by acetic acid. It exhibits all the properties of uric acid. The fact is, that the precipitate which usually falls when urine cools consists chiefly of phospat of lime and uric acid. It may be dissolved in water, and then evaporated to dryness. If the solution is heated and evaporated to dryness, it is a crystalline carbonate of lime if uric acid is present. The proportion of uric acid varies considerably in urine. It crystallizes in small red prisms, partly on the surface of urine mixed with some nitric acid, and left exposed to the air.

During intermittent fevers, and especially during diseases of the liver, a copious secretion of a brick-red colour is deposited from urine. This sediment is the rosic acid of Proust. Scheele considered this sediment as uric acid mixed with some phospat of lime; and the same opinion has been entertained by other chemists; but Proust affirms that it consists chiefly of a different substance, to which he has given the name of rosic acid from its colour, mixed with a certain proportion of uric acid and phospat of lime. This rosic acid, he informs us, is distinguished from the uric by the facility with which it dissolves in water; by the green or blue precipitate which it occasion in medicines or urine; and by the little tendency which it has to crystallize it.

If fresh urine is evaporated to the consistence of a syrup, and uric acid is then precipitated into it, a precipitate appears which possesses the properties of uric acid. Scheele first discovered the presence of benzoic acid in urine. He evaporated it to dryness, separated the saline part, and applied heat to the residuum. The benzoic acid was sublimed, and found crystallized in the receiver. Considerable quantities of benzoic acid may thus be obtained from the urine of horses and cows, where it is much more abundant than in human urine. In human urine it varies from 330 to 350 of the whole. Proust affirms that the acid obtained by Scheele's process is not the benzoic, but another possessed of similar properties; but differing in this circumstance, that nitric acid decomposes it, whereas only whitens benzoic acid.

When an infusion of tan is dropped into urine, a white precipitate appears, having the properties of the combination of tan and albuminum, or an acid. This character of urine, therefore, contains albumen or gelatine. These substances have been suspected to be in urine, but their presence...
If urine is slowly evaporated to the constancy of a syrup, a number of crystals make their appearance on its surface; these possess the properties of murat of soda. Urine therefore contains urat of soda. It is well known that murat of soda crystallizes in cubic form; but when obtained from urine it has the form of octahedrons. This singular modification of its form is owing to the action of urea. It has been long known that urine saturated with murat of soda deposits that salt in regular octahedrons.

The saline residuum which remains after the separation of urine from crystallized urine by means of alcohol has been long known under the name of fusible salt of urine and microsomic salt. Various methods of obtaining it have been given by chemists; from Boerhaave, who first published a process, to Rouelle and Chaulnes, who gave the method just mentioned. If the urine mass is dissolved in a sufficient quantity of hot water, and allowed to crystallize spontaneously in a closed vessel, two sets of crystals are gradually deposited. The lowest set has the figure of flat rhomboidal prisms; the uppermost, on the contrary, has the form of rectangular tablets. These two may be easily separated by exposing them for some time to a dry atmosphere. The rectangular tablets effloresce and fall to powder, but the rhomboidal prisms remain unaltered.

When these salts are examined, they are found to have the properties of phosphates. The rhomboidal prisms consist of phosphate of ammonia united to a little phosphat of soda; the rectangular tablets, on the contrary, are phosphat of soda and phosphate of ammonia. Urine, then, contains phosphate of soda and phosphate of ammonia.

When urine is cautiously evaporated, a few cubic crystals are often deposited among the other salts; these crystals have the properties of phosphat of ammonia. Now the usual form of the crystals of murat of calcium is the octahedron. The change of its form in urine is produced also by urea. This salt is obtained in greater abundance when the crystals of urea obtained from the alcohol solution are dissolved.

When urine is boiled in a silver basin it blackens the basin; and if the quantity of urine is large, small crusts of sulphuret of silver may be detached. Hence we see that urine contains sulphur. This sulphuret exhalés, along with the carbonic acid when the urine putrefies; for the fumes which separate from urine in that state blacken paper stained with acetate of lead.

Urine, then, contains the following substances:

1. Water,
2. Phosphoric acid,
3. Phosphat of ammonia,
4. Phosphat of magnesium,
5. Carboxic acid,
6. Carbonat of lime,
7. Uric acid,
8. Rosic acid,
9. Benzoic acid,
10. Gelatine and albumen,
11. Urca,
12. Resin,
13. Murat of soda,
14. Phosphat of soda,
15. Phosphat of ammonia,
16. Murat of ammonia,
17. Sulphur.

These are the only substances which are constantly found in healthy urine; but it contains also occasionally other substances. Very often murat of potass may be distinguished through the crystals which form during its evaporation. The presence of this is always detected by dropping cautiously some tartaric acid into urine. If it contains murat of potass, there will precipitate a little tartar, which may easily be recognized by its properties.

Urine sometimes also contains sulphat of soda, and even sulphat of lime. The presence of these salts may be ascertained by pouring into urine a solution of murat of barytes; a copious white precipitate appears, consisting of the barytes-combined with phosphoric acid, and with sulphuric acid if any is present. This precipitate must be treated with a sufficient quantity of muriatic acid. The phosphat of barytes is dissolved, but the sulphat of barytes remains unchanged.

No substance putrefies sooner, or exhalés a more detestable odour during its spontaneous decomposition, than urine; but there is a very great difference in this respect in different urines. In some, putrefaction takes place almost instantaneously as soon as it is voided; in others, scarcely any change appears for a number of days. Fourcroy and Vaquelin have ascertained that this difference depends on the quantity of gelatine and albumin which urine contains. When there is very little of these substances present, urine remains long unchanged; on the contrary, the greater the quantity of gelatine or albumen, the sooner does putrefaction commence. The putrefaction of urine, therefore, is in some degree the test of the health of the person who has voided it; for a superabundance of gelatine in urine always indicates some defect in the power of digestion.

The rapid putrefaction of urine, then, is owing to the action of gelatine on urea. We have seen already the facility with which that singular substance is decomposed; and that the new products into which it is changed are: ammonia, carboenic acid, and acetic acid accordingly, the putrefaction of urine is announced by an ammoniacal smell. Muclulaginous flakes are deposited, consisting of part of the gelatinous matter. The phosphoric acid is saturated with ammonia; and the phosphat of lime, in consequence, is precipitated. Ammonia combines with the phosphat of magnesia; and forms with it a triple salt, which crystallizes upon the sides of the vessel in the form of white crystals, composed of six-sided prisms, terminated by six-sided pyramids. The uric and benzoic acids are saturated with ammonia; the acetic acid, and the carbonic acid, which are the products of the decomposition of the area, are also saturated with ammonia; and notwithstanding the quantity which exhalés, the production of this substance is so abundant, that there is a quantity of unsaturated alkali in the liquid. Untertreated urine, therefore, contains chiefly the following substances, most of which are the products of putrefaction:
Ammonia, Carbonat of ammonia, Phosphat of ammonia, Phosphat of magnesium and ammonia, Urat of ammonia, Acetat of ammonia, Benzet of ammonia, Muriat of soda, Muriat of ammonia;

besides the precipitated gelatine, and phosphat of lime.

The distillation of urine produces almost the same changes: for the heat of boiling water is sufficient to decompose urea, and to convert it into ammonia, carbonic, and acetic acids. Accordingly, when urine is distilled, there comes over water, containing ammonia dissolved in it, and carbonat of ammonia in crystals; the acids contained in urine are saturated with ammonia, and the gelatine and phosphat of lime precipitate.

Such are the properties of human urine in a state of health: but this excretion is singularly modified by disease; and the changes to which it is liable have attracted the attention of physicians in all ages, because they serve in some measure to indicate the state of the patient and the progress of the disease under which he labours. The following are the most remarkable of these changes that have been observed:

1. In inflammatory diseases the urine is of a red colour, and peculiarly acid; it deposits no sediment on standing, but with oxymuriat of mercury it yields a copious precipitate.

2. During jaundice the urine has an orange-yellow colour, and communicates the same tint to linen. Muriatic acid renders this urine green, and thus detects the presence of a little bile.

3. About the end of inflammatory diseases the urine becomes abundant, and deposits a copious pink-coloured sediment, composed of roasic acid, a little phosphat of lime, and uric acid.

4. During hysterical paroxysms, the urine usually flows abundantly. It is limpid and colourless, containing much salt, but scarcely any urea or gelatine.

5. Mr. Berthollet observed that the urine of gouty persons contains usually much less phosphoric acid than healthy urine. But during a gouty paroxysm it contains much more phosphoric acid than usual; though not more than constantly exists in healthy urine.

6. In general dropsy, the urine is loaded with albumen, and becomes milky, or even coagulates, when heated, or at least when acids are mixed with it. In dropsy from diseased liver, no albumen is present, the urine is scantly, high-coloured, and deposits the pink-coloured sediment.

7. In dyspepsia, the urine always yields a copious precipitate with tan, and putsrefy rapidly.

8. The urine of rickety patients is said to be loaded with phosphat of lime, or, according to others, with oxalat of lime.

9. In diabetes, the urine is sweet-tasted and often loaded with saccharine matter. In one case, the urine emitted daily by a diabetic patient, according to the experiments of Cruikshank, contained 20 ounces of sugar.

The urine of other animals differs considerably from that of man. For the analyses of the urine of quadrupeds hitherto made, we are chiefly indebted to Rouelle junior. The following facts are true, though named by that chemist, and by the late experiments of Fourcroy and Vauquelin:

1. The urine of the horse has a peculiar smell: after exercise it is emitted thick and milky; at other times it is more permanent, but becomes milky soon after its emission. When exposed to the air, its surface becomes covered with a crust of carbonat of lime. It gives a green colour to syrup of violets, and has the consistence of mucilage. The following are its constituents as estimated by Fourcroy and Vauquelin from their experiments:

- Carbonat of lime: 0.111
- Carbonat of soda: 0.009
- Benzet of soda: 0.024
- Muriat of potas: 0.009
- Urea: 0.007
- Water and mucilage: 0.940

1.000

From the late experiments of Mr. Giese, we learn that the quantity of benzet of soda varies considerably in the urine of horses. In some specimens he found it in abundance and easily precipitated by muriatic acid. In others there was little or none. He could detect no benzoic acid in the food of horses. Hence he considers it as formed within the animal, and he thinks that it appears only in cases of disease.

II. The urine of the cow has a strong resemblance to that of the horse; it has nearly the same colour, and the same mucilaginous consistence. It tinges syrup of violets green, and deposits a gelatineous matter. On standing, small crystals are formed on its surface.

It contains, according to Rouelle,

1. Carbonat of potas, 4. Benzoic acid,
2. Sulphat of potas, 5. Urea,
3. Muriat of Potas,

III. The urine of the camel was also examined by Rouelle. Its colour resembles that of the urine of the cow; its colour is that of brown, but it is not brown, and does not deposit carbonat of lime. It gives a green colour to syrup of violets, and effervesces with acids like the urine of the horse and cow. Rouelle obtained from it,

1. Carbonat of potas,
2. Sulphat of potas,
3. Muriat of potas,
4. Urea.

IV. The urine of the rabbit has been lately analysed by Vauquelin. When exposed to the air, it becomes milky, and deposites carbonat of lime. It gives a green colour to syrup of violets, and effervesces with acids. That chemist detected in it the following substances:

1. Carbonat of lime,
2. Carbonat of magnesia,
3. Carbonat of potas,
4. Sulphat of potas,
5. Sulphat of lime,
6. Muriat of potas,
7. Urea,
8. Gelatine,

V. Vauquelin has also made some experiments on the urine of the guinea-pig, from which it appears that it resembles the urine of the other quadrupeds. It deposits carbonat of lime, gives a green colour to syrup of violets, and contains carbonat and muriat of potas, but no phosphat zor uric acid.

Thus it appears that the urine of the granivorous quadrupeds agrees with that of man in containing urea, but differs from it materially in being destitute of phosphoric acid, phos- phate, and uric acid. Whether the urine of the granivorous quadrupeds contains those last substances has not been ascertained, but it is probable that it does.

URSA, the bear, in astronomy, a name common to two constellations of the northern hemisphere, near the pole, distinguished by no peculiar character. The ura major, or the great bear, according to Ptolemy's catalogue, consists of twenty-five stars: according to Tycho's, of sixty-six: but in the British catalogue we have two hundred and fifteen.

The ura minor, or little bear called also Charles's vain, and the Greeks cynoura, by its neighbourhood to the pole, gives the denomination 8 Perseus, bear, thereta. Ptolemy and Tycho make it of eight stars, but Flamsteed of fourteen.

URUS, bear, a genus of quadrupeds of the order Carniva, in which the generic character is, from teeth six both above and below: the two lateral ones of the lower jaw longer than the rest and lobed; with smaller or secondary teeth at their internal bases; canine teeth solitary or double in each side, the first or second being proximated to the canine teeth; tongue smooth; snout prominent; eyes furnished with a nictitating membrane. There are four species.

1. Ursus arctos. The common bear, with a coat of fur as to size and colour, is a native of almost all the northern parts of Europe and Asia, and is even said to be found in some of the Indian islands, as Ceylon, &c. It is a large animal, and frequents woods and unoccupied places, and feeds chiefly on roots, fruits, and every vegetable substance, but occasionally preys on animals. In the Alpine regions the bear is brown; in some other parts of Europe, black; and in some parts of Norway it is white, or nearly so. It is almost entirely vegetable food; the brown, the black, the grey, and the white bears are, therefore, to be considered as the same species; yet it is observed that the brown and black varieties differ somewhat in their manner of life; the black confining itself to a certain species of fish, and avoiding other animals, and destroying lambs, kids, and even sometimes cattle, and sucking the blood in the manner of the cat and weasel tribes. Linnæus adds, that the bear has a habit of blowing up his prey, and of hiding or burning a part of it. Bears are reported to particularly love honey, in search of which they will climb trees, in order to get at nests of wild bees; for the bear, notwithstanding his awkward form, is expert in climbing and sometimes takes up his residence in a hollow of a very large tree. The bear also catches and devours fish, occasionally in quest of the banks of rivers for that purpose.

The bear passes a considerable part of
winter in a state of repose and abstinence; emerging only at distant intervals from his den, and again concealing himself in his retreat till the opening of the vernal season. The females are said to continue their isolation much longer than the males, and it is during this period that they bring forth their young, which are commonly two in number. These animals, when imagined to be but shapeless masses, gradually located and fashioned into regular form by the parent; an opinion now sufficiently exploded. The young, however, though not shapeless, have a different aspect from the grown animal; the soot being much sharper, and their colour yellowness: their ears are said to be blind for nearly the space of a month.

2. Ursus Americana, American bear. This, which is now considered as a distinct species, and not to be confounded with the black bear of Europe, has a long, pointed nose and narrow forehead: the cheeks and throat of a yellow-brown colour; the hair on the whole body and limbs of a glossy black, and smoother and paler than that of the European kind. It is also said to be in general smaller than the European bear, though instances have been known in which its size, at least, equalled the European, since Mr. Harlan from an island in the Pacific killed a bear weighed in Florida which weighed forty-seven pounds.

This animal inhabits all the northern parts of America, migrating occasionally from the northern to the more southerly parts in quest of food, which is said to be entirely vegetable; and it is even affirmed, that, when pressed by extreme want, they will still neglect all animal food whenever they can obtain an supply of roots and grain. They, however, sometimes destroy fish, and particularly herring, when these fish happen to come up into the creeks in shoals. They are said to continue in their winter retreats, either in dens beneath the snow under ground, or in the hollows of old trees, for the space of five or six weeks without food.

3. Ursus maritimus, polar bear. This is a far larger species than the common bear, and is said to have been sometimes found of the length of twelve feet. The head and neck are of a more lengthened form than in the common bear, and of much more in proportion. The whole animal is white, except the tip of the nose and the claws, which are jet-black: the ears are small and rounded; the eyes small; the teeth of an extraordinary magnitude; the hair is of a great length, and the limbs are extremely large and strong. See Plate Nat. fig. 415. It seems confined to the very coldest parts of the globe; being found within 80 degrees of north latitudes, as far as any navigators have yet penetrated. The shores of Hudson's-bay, Greenland, and Spitsbergen, are its principal places of residence; but it is said to have been accidentally carried on floating ice as far south as Newfoundland. This species seems to have often come in this state among the white variety of the common bear, which is occasionally found in the northern regions.

The polar bear is an animal of tremendous strength and ferocity. Barentz, in his voyage in search of an ocean passage to China, and the proof of the ferocity of these animals, in the island of Nova Zembla, where they at

lacked his teamen, seizing them in their mouths, carrying them off with the utmost ease, and devouring them in the sight of their comrades. It is said that they will attack and tear to pieces an old cow, a great distance from shore; and have sometimes been with much difficulty repelled. Their usual food consists of seals, fish, and the carcasses of whales; but, when on land, they prey on deer, and other animals, as bears, young birds, &c. They also eat various kinds of berries which they happen to find. They are said to be frequently seen in Greenland in great droves, alarmed by the scent of the flesh of seals; and will sometimes surround the habitations of the natives, and attempt to break in; and it is added, that the most successful method of repelling them is by the smell of burnt feathers. They grow extremely fat, a hundred pounds of fat having been taken from a single beast. The flesh is said to be coarse, but the skin is valuable for coverings of various kinds, and the Greenlanders often wear it as a clothing. The split tendons are said to form an excellent thread; and the summer they reside chiefly on the ice-islands, and are frequently from one to another; being extremely expert swimmers. They have been seen on these ice-islands at the distance of more than eighty miles from the shore, and feeding as they float along. They winter in dens formed in the vast masses of ice, which are piled in a stupendous manner, leaving great caverns beneath: heretofore, breed, and bring one or two young at a time, and sometimes, but very rarely, three. The affection between parent and young is so great, that they will sooner die than desert each other. They follow their dams a very long time, and grow to a large size before they quit them.

During winter they retire, and bed themselves deep beneath the snow, or else beneath the fixed ice of some eminence, where they pass in a state of torpidity the long and dismal Arctic night, appearing only with the return of the sun.

The skins of the polar bear, says Mr. Pennant, were formerly offered by the hunters in the arctic regions to the high altars of cathedrals and other churches, for the priest to stand on during the celebration of mass in winter.

4. Ursus gulo, glutton. This animal is a native of the most northern parts of Europe and Asia, occurring in Sweden, Norway, Lapland, and Siberia, as well as in some of the Alpine regions, and in the forests of Poland and Courland. It is also found in the northern parts of America, being not uncommon about Hudson's Bay.

The glutton is considerably larger than a badger, measuring a yard from nose to tail, and the tail about a foot; but it seems to vary in size, and is often less than this. The muzzle, as far as beyond the eyes, is blackish brown, and covered with hard shining hair: over the forehead, down the sides of the head, between the eyes and ears, runs a whitish or ash-coloured band or fillet: the top of the head and whole length of the back are blackish, the rump widening somewhat over the sides as it passes on, and again lessening or contracting towards the tail. In the American variety a whitish or ash-coloured band or border runs across the body, in the European kind as the ferruginous one in the European kind.

The glutton, as its name imports, has the character of a very voracious animal, preying indiscriminately both on fresh prey and carrion. One of which was kept at Dresden, and fed on flesh of a day, without being satisfied. It attacked dog, field-mice, &c. and even sometimes the larger cattle; and it is said to sit on the branches of trees, and suddenly to spring down on such animals as happen to pass beneath; tearing them, and sucking the blood, till they fall down through faintness, when it begins to devour the spoil. In winter it seeks out and catches ptarmigan under the snow. What it cannot devour at once, it is said to hide under ground, or in the cavity of some tree. It is said to be an animal of uncommon fierceness and strength; and will sometimes dispute the prey both with the wolf and bear. It is also extremely fed. It breeds once a year, and brings from two to four young at a litter. The fur is much used for muffs, linings, &c. Those skins are said to be preferred which have least of the ferruginous patch, and for this reason the Siberian variety, which is blacker than the European, is esteemed. The ursus luscus, or wolverine, appears to be a variety of this animal.

5. Ursus lotor, the raccoon. This is a native of the new world, and is principally inhabited of the northern parts of America. It is also found in some of the West Indian islands. Its colour is grey; the face white; the eyes each imbedded in a large patch of black, which forms a kind of band across the forehead. It is frequently found running down the nose. The visage is shaped like that of a fox, the forehead being broad and the snout short; the eyes are large and greenish; the ears short and slightly rounded; and the upper jaw is longer than the lower: the tail, which is covered with bushy hair, tapers to the end, and is annulated with several black bars; the body is broad, the back arched, the limbs rather short, and the fore legs shorter than the hinder; the animal is covered with thick and long hair, which has a somewhat upright growth: the feet are dasy, and have five toes with very sharp claws. The colour of the raccoon is generally a dark brown, mixed with black, as sugar-canes, various sorts of fruit, as apples, cheremuts, &c. It is also supplied to devour birds and their eggs, and is, therefore, considered as an enemy to poultry. It avidly feeds by night, and by day keeps in its hole, except in dull weather. In winter, and in very bad weather, it keeps altogether within; and is popularly believed to live like the bear, by sucking its paws. The raccoon, however, is an active and sprightly animal when taken into a state of domestication. It has a kind of oblique gait in walking, can leap and climb with great ease, and is very frequently seen on trees. It is easily tamed, and will eat the food of the Americans, and will live on bread, milk, fish, eggs, &c. It is particularly delighted with sweets of every kind, and has as great a dislike to acids. In eating, it commonly sits on its hind legs, and uses its fore feet in the manner of hands. It has a way of dipping
all manner of dry food that is given it into water, it eats it; as well as of rolling it between its paws for some time. When it kills birds, it proceeds exactly in the manner of a polecat; first biting off the head, and then skeling the body. It eats but little, and is a very cleanly animal. It is extremely expert in opening oysters, on which, as well as on crabs and various other kinds of shell-fish, it frequently feeds in its wild state. It is, when tamed, extremely active and playful: but it is of a capricious disposition, and not easily reconciled when offended. When angry, its voice is like a hoarse bark, and at other times soft and sharp. In its wild state it generally inhabits the hollows of trees; but in a domestic state shows no particular inclination for warmth; nor is it observed to be desirous of lying on straw, or any other substance, in preference to the bare ground. It sleeps from about midnight to noon, at which time it comes out for food and exercise. According to Linneus, the raccoon has a wonderful antipathy to hogs' bristles, and is much disturbed at the sight of a brush. It produces three young at a birth; a fact which, says Linneus, it commonly takes place in the month of May. The fur of the raccoon is used by the hatters, and is considered as next in merit for this purpose to that of the beaver.

In meadow, fields, or woods, the badger is an inhabitant of all the temperate parts of Europe and Asia. Its usual length is about two feet from the nose to the tail, which measures six inches. It is an animal of very clumsy make, being thick-necked and thick-bodied, with very short legs. It体制机制ly nests in a hole or den under ground, out of which it emerges by night in quest of food; feeding chiefly on roots and fruits; but it will also devour frogs, worms, &c. The badger is of an uniform grey colour on the upper parts, and the throat, breast, belly, and legs, are black: the face is white, and along each side of the head runs a long and somewhat triangular or pyramidal band of black, including the eyes and very short ears. It is commonly met with in holes or cellars, under houses, or in the ground. Authors have sometimes made a distinction between what they call the sow badger and the dog badger; but this is supposed to be perfectly untenable, and if there is any perceptible variation, it is probably no other than a mere sexual difference. The hair of the female, both on the body, limbs, and tail, is very thick; and the teeth, legs, and claws, are very strong; so that he makes a very vigorous enemy. When taken young, the badger may be easily tamed, and generally prefers raw flesh to every other food in a state of captivity. It is a very cleanly animal, and is observed to keep its subterraneous chamber extremely neat. The female produces about three or four young: this happens in summer; and, according to the count de Buffon, the parent seizes on young rabbits, which she claws out of their burrows, birds, eggs, snakes, and any other animals, in order to feed her young. Like the bear, this animal is also fond of honey, and will attack hives in order to obtain it. The badger sleeps a great deal, especially during winter, when he imitates the practice of the bear, confining himself to his den in a state of semi-torpor.

7. Ursus labradorius, American badger. In its general appearance this extremely resembles the common badger, and might almost be taken for the same animal, except in the under parts which are somewhat smaller, and the black bands on the face are much narrower and do not include the eyes, but commence behind them, and run along the top of the neck: the ears are surronded with black: the upper parts of the body are of the same colour as in the common badger, but rather paler, and with a slight yellowish cast; and the breast and belly are of a light ash-colour, instead of black: the legs are of a dusky brown: the claws are at least as long and strong as in the European badger, if not more so. This species is rather scarce in America. It is found in the neighbourhood of Hudson's-bay, and in Terra de Ladrador, and as Mr. Pennant suspects, as low as Pennsylvania, where it is called the ground-bog.

URTICA, a genus of plants of the class monoeccia, and order tetrameridia; and in the natural system classed under the 33rd or 83rd order, s. abride. The male flower has a calyx of four leaves, and a pistil; a monoeccia, central, un-furnished. The female has a bivalve calyx; and a single, oval, glossy seed. There are 59 species, three of which are British plants: 1. The planiflora, Roman nettle, has a stalk branched, two or three feet high. Leaves opposite, oval, serrated, stinging. Fruit globose. 2. The uren, less stinging nettle, has a stem a foot high. Leaves roundish, deeply serrated, opposite. The stings are very very curious microscopic objects: they consist of an exceedingly fine-pointed, tapering, hollow substance, with a perforation at the point, and a bag at the base. When the spring is pressed upon, it readily perforates the skin, and at the same time forces up some of the acrimonious liquor contained in the bag into the wound. 3. The donnca, common nettle, has a square firm stem, three or four feet high. Leaves heart-shaped, long-pointed, serrated at the edges, with wings. Flowers in long catkins. The aculei, or stings of the nettle, have a small bladder at their base full of a burning corrosive liquor: when touched, they excite a bluster, attended with a violent itching, the stings appear to be tubular, or perforated at the top, nor any visible liquor to be infused into the puncture made by it in the flesh. It seems certain, however, that some of this liquor is imnizated into the wound, though invisibly, since the stings of the dried plant excite no pain.

Nettle-tops in the spring are often boiled and eaten by the common people instead of cabbage-greens. In Arran, and other islands, a remnant is made of a strong decoction of nettles: a quart of salt is put to three pints of the decoction, and boiled up for the common spoonful of this liquor will coagulate a large bowl of milk very readily and agreeably. The stalks of nettles are so like in quality to hemp, that in some parts of Europe and Siberia they are cultivated in cloth, and paper has been made of them. The whole plant, particularly the root, is esteemed to be diuretic, and has been recommended in the jaundice and nephritic complaints. The roots boiled will dye yarn of a yellow colour. The larvae, or caterpillars, of many species of butterflies, feed on the green plant; and sheep and oxen will readily eat dried.

USAGE, in law, differs from custom and usage, denoting a usual practice, custom, or other inheritance, by usage, though he may by prescription. B. Co. 65.

USANCE, in commerce. See INTEREST.

USE, is a trust and confidence reposed in another who is tenant of the land, that he is to dispose of the land according to the intention of cestue que se, or him in whose use it was granted, and suffer him to take the profits. 2 Black. 328.

By st. 27 H. VIII. c. 10, commonly called the statute of uses, or the statute for transferring uses into possession, the cestue que se is considered as the real owner of the estate; whereby it is enacted that, when any person is seized of lands to the use of another, the person mulitified to the use in simple fee, life, for life, or years, or otherwise, shall grant the possession, in the like estate, as he has of the use, trust, or confidence; and thereby the act makes cestue que se to be the person who yields any possession under law and equity. 2 Black. 302.

USES, superadditions. See Mortmain.

Uses and customs of the sea, are certain maxims or rules which form the basis of the maritime jurisprudence, by which the policy of navigation, and the commerce of the sea, are regulated.

These uses and customs consist of three kinds of regulations, the first called the laws or judgments of Oleron; the second, regulations made by the merchants of Wisby, a city in the island of Gotland, in the Baltic, antiently much famed for commerce; and the third, a set of regulations made at Lubeck, by the Hanseatic League.

USQUEBERA, a strong compound liquor, chiefly taken by way of draught.

There are several different methods of making this liquor; but the following is esteemed one of the best: To two gallons of grappa, or other spirit, put a pound of Spanish liqueur, half a pound of raisins of the sun, four ounces of currants, and three of sliced dates; 10 pounds of sugar, 1 pound of honey, 1 pound of the flowers of rosemary, of each two ounces; cinamon and mace, well bruised, nutmegs, aniseed, and coriander-seeds, bruised likewise, of each four ounces; citron, or lemon and orange peel, scraped, of each an ounce; let all these infuse forty-eight hours in a warm place, often shaking them together: then let them stand in a cool place for a week: after which the clear liquor is to be decanted off, and to it are to be put an equal quantity of new white port, and a gallon of canary: after which, it is to be sweetened with a sufficient quantity of double-refined sugar.

USTERIA, a genus of plants of the class and order monoecia monogynia. The calyx is four-toothed; corolla funnel-form, four-lipped; capsule one-seeded, two-celled. There is one species, a shrub of North Guinea.

USURY, in a strict sense, is a contract upon the loan of money, to give the lender a certain profit for the use of it, upon all events;
whether the borrower made any advantage of it, or the lender suffered any prejudice for want of it, or whether, it shall be repaid on the appointed time or not; and in a large sense, it seems undue advantage taken by a lender against a borrower, came under the notion of usury. Haw. 243.

The statute 12 Anne, c. 16, enacts that no person, upon any contract which shall be made, shall take for loan of any money, wares, &c., which shall value 5s. or more in the year, the rent of 100l. for a year; and all bonds and assurances for the payment of any money to be lent upon usury, whereupon or whereby there shall be reserved or taken above five pounds in the hundred, shall be null, and every person who shall receive, by means of any corrupt bargain, loan, exchange, shift, or interest, of any wares or other things, or by any deceitful way, for forbearing or giving day of payment for one year, for their money or other things, shall be st. for 100l. for a year, &c.; shall forfeit treble the value of the moneys or other things lent.

But if a contract, which carries interest, is made in a foreign country, our courts will direct the payment of interest according to the law of that country. Thus, Irish, American, Turkish, and Indian interest, have been allowed in our courts, to the amount of 12l. per cent. For the moderation or exorbitance of interest depends upon local circumstances; and the refusal to enforce such contracts would put a stop to all foreign trade. 2 Black. 463.

In an action brought for usury, the statute made against it must be pleaded; and in pleading an usurious contract as a bar to an action, the whole matter is to be set forth specially, because it lies within the party's own privity; yet, on an information on the statute for making such contract, it is sufficient to mention the corrupt bargain generally, because matters of this kind are supposed to be privily transacted; and such information may be brought by a stranger. 1 Hawk. P. C. 238. Likewise upon an information on the statute against usury, he that borrows the money may be a witness, after he has paid the same.

UTENSILS, in a military sense, are necessaries due to every soldier, and to be furnished by his host where he is in quarters, viz. bed with sheets, a pot, a glass or cup to drink out of, a dish, a place at the fire, and a candle.

Utensils, &c. directed to be provided for the use of regimental hospitals:

In page 19, of the Regulations for the Sick, it is stated, that each hospital ought to be furnished with a slip-bath, or bathing-tub, two water-buckets, one dozen of Osnaburg towels, one dozen of flannel, half a dozen of large sponges, combs, razors, and soap; two large kettles, capable of making soup for 30 men, two large tea-kettles, two large tea-pots, two saucepans, 40 tin cups of one spoon, two spoons, a dozen of knives and forks, two close-stools, two bed-pans, and two earthern vessels.

A regiment consisting of 1000 men, and provided with three medical persons, ought to be furnished with hospital necessaries and utensils for at least 40 patients. It should be provided with 40 cotton night-caps; 40 sets of bedding, in the proportion of four for every hundred men; each set consisting of one pallasse, one straw matress, one bolster, three sheets, two blankets, and one rug.

For regiments of smaller number, the quantity of which are able to dry the necessaries will of course be proportionally reduced.

UTENSILS, BAKERY. The following list of bakery utensils, being the proportion requisite for an army of 36,000 men, has been extracted from the British Commissary, to which we are indebted to refer the military reader for a specific description of field ovens, &c. and field bakery, page 16, &c.

12 double iron ovens, 11 feet long, 9 feet diameter, and 3 feet high; 28 troughs and their covers, 10 feet long, 3 feet wide, and 3 feet deep, to kindle the dough.

12 large double tents (having double coverings), 32 feet long, and 24 feet wide, to make the bread in.

4 ditto, to cool and deposit the bread in.

2 ditto, to deposit the meal and empty sacks in.

2000 boards, 8 feet long, and 14 inch wide, to carry the bread to the oven, and back again.

24 small scales to weigh the dough, with weights from half an ounce to 6lb.; 24 small lamps for night work; 24 small hatchets; 24 scrapers, to scrape the dough from the troughs; 12 copper kettles, containing each from ten to twelve pails of water; 12 trevets for ditto; 12 barrels with handles, to carry water, containing each from 5 to 7 pails.

12 pails, to draw water; 24 yokes and hooks, to carry the barrels by hand; 24 iron peles, to slove and draw the bread from the ovens; 24 iron pitchforks, to turn and move the firewood and coals in the ovens; 24 spare handles, 14 feet long, for the peles and pitchforks; 24 rakes, with handles of the same lengths, to clear away the coals and cinders from the ovens; 4 large scales, to weigh the sacks and barrels of meal, and capable of weighing 500lb.; 4 triangles for the said scales; to each must be added 500lb. of weights, 3 of 100lb. each, 2 of 50lb. each, and downwards to half a pound.

UTERUS. See Anatomy.

UTLAMAGO capicudo quando utulagaw in uno conscribe et postea fugit in alium. A wit for the taking of an outlawed person in one county, who afterwaods flies into another.

UTRICULARIA, a genus of plants of the class diurana, and order monogynia; and in the natural system arranged under the 24th order, corollas of the flowers are entire, with a nectarium resembling a spur; the corolla diphyllous and equal; the capsule unicorial. There are 13 species, two of which are natives of Britain. They have been applied for ornamental use.

UVARIA, a genus of plants of the class dicotyledon, and order papilionac; the calyx is three-leafed; petals six; berries numerous, pendent, four-seeded. There are eleven species, shrubs and trees of the East Indies.

VULGAR, a genus of birds belonging to the order of accipiters. The beak is straight, and crooked at the base; the head has no feathers, on the fore part there being only naked skin, and the tongue generally biled. There are twenty-one species. The most remarkable are,

1. Grypus, the condor, which is not only the largest of this genus, but perhaps of all birds, and is said to weigh between 20 and 25 years of age. It is very nearly, if not precisely, the truth, which states the extent of wing at about 11 feet. The bill is strong, moderately hooked, and blunt at the tip, which is white, the rest of it being of a dusky colour. On the top of the head runs a kind of carunculated substance, standing up like the comb of a cock. The head and neck are slightly covered with brown down, in some parts nearly bare, and here and there a carunculated part, as in the neck of a turkey. The lower part of the neck is surrounded with a cluster of dull white and hairy kind of feathers. The upper parts of the body, wing, and tail, are black, except that the middle wing-coverts have whitish ends, and the greater coverts half black half white. The nine or ten first quills are yellow, the rest white, with the tips only black; and when the wings are closed, producing the appearance of the bird having the back white. The under parts of the body are rather slightly covered with feathers; but those of the thighs are pretty long. The legs are stout and brown; claws black and white.

These birds are said to make their nests among the inaccessible rocks, and to lay two white eggs, larger than those of a turkey; are very destructive to sheep, and will in troops often attempt calves; in which case, some of them first pick out the eyes, whilst others attack the poor animal on all sides, and soon tear him to pieces. This gives rise to the following song, used by the natives of Chili: One of them wraps himself up in the hide of a fresh-killed sheep or ox, and lies still on the ground; the condor, supposing it to be lawful prey, flies down to secure it, when the person concealed lays hold of the legs of the bird, his hands being well covered with gloves; and immediately his comrades, who are concealed at a distance, run in, and assist to secure the depredator, by falling on him with sticks till they have killed him.

2. The perorniters, or Egyptian vulture. The appearance of this bird is so horrid as well be imagined, viz. the face is naked and wrinkled; the eyes are large and black; the beak black and hooked; the talons large, and extending ready for prey; and the whole body polluted with filth: these are qualities enough to make the beholder shudder with horror. Notwithstanding this, the inhabitants of Egypt cannot be thankful enough to Providence for this bird. All the places round Cairo are filled with the dead bodies of these birds, and thousands of these birds fly about, and devour the carcasses before they putrefy and fill the air with noxious exhalations. The inhabitants of Egypt, and after them Maitet in Description of Egypt, say, that they yearly follow the caravan to Mecca, and devour the
A few of the slaughtered beasts, and the carcasses of the camels which die on the journey. They do not fly high, nor are they afraid of men. If one is killed, all the rest surround him in the same manner as do the Royton crows; they do not quit the places they frequent, though frightened by the explosion of a gun, but immediately return thither.

3. The aura, or carrion vulture, according to Latham, is about the size of a turkey, though it varies in size in different parts. The bill is white; the end black; ridges bluish saffron-colour. The head, and part of the neck, are bare of feathers; end of a red, or rather rufous colour. The sides of the head warted, not unlike that of a turkey. The whole plumage is brown-black, with a purple and green gloss in different reflections; but in some birds, especially young ones, greatly verging to dirty-brown. The feathers of the quills and tail are blacker than the rest of the body. The legs are flesh-colour; the claws black.

4. The sagittarius, or secretary, is a most singular species, being particularly remarkable from the great length of its legs; which at first sight would induce one to think it belonged to the gralle, or waders; but the characters of the vulture are so strongly marked, as to leave no doubt as to which class it belongs. The bird, when standing erect, is full three feet from the top of the head to the ground. The bill is black, sharp, and crooked, like that of an eagle; the head, neck, breast, and upper parts of the body, are of a bluish ash-colour; the legs are very long; 'twixt those of a heron, and of a brown colour; claws shortish, but crooked, not very sharp, and of a black colour; from the hind-head springs a number of long feathers, which hang loose behind like a pendant crest; these feathers arise by pairs, and are longer as they are lower down on the neck; this crest the bird can erect or depress at pleasure; it is of a dark colour, almost black; the webs are equal on both sides, and rather cedled; and the feathers, when erected, somewhat inclined towards the neck; the two middle feathers of the tail are twice as long as any of the rest. This singular species inhabits the internal parts of Africa, and is frequently seen at the Cape of Good Hope. It is also met with in the Philippine islands.

As to the manners of this bird, it is on all hands allowed that it principally feeds on rats, lizards, snakes, and the like; and that it will become familiar: whence Somner is of opinion that it might be made useful in some of our colonies, if encouraged, towards the destruction of those pests. They call it at the Cape of Good Hope stagneater, i.e. snake eater. A great peculiarity belongs to it, perhaps observed in nother; which is, the faculty of striking forwards with its legs, never backwards. Dr. Solander saw one of these birds take up a snake, small toroise, or suchlike, in its claws; when dashing it thence against the ground with great violence, if the victim was not killed at first, it repeated the operation till the end was answered; after which it ate it up quietly. Dr. J. R. Forster mentioned a similar instance, which he says was supposed to be peculiar to this bird; that is, that it might by any accident break the leg, the bone would never unite again.

The Editor of this work saw a secretary some years ago at Exeter-exchange. The dexterity with which it struck ends, &c. with its hard feel was surprising. How far it might have been tutored to this exercise is impossible to say.

2. The apex, or king vulture, inhabits South America; is the size of a bun turkeys; feeds on serpents, lizards, frogs, rats and carrion; flies high. See Plate Nat. Hist, fig. 420.

VULVA. See Anatomy.

VULVARIA, a genus of the hexandra monogynia class of plants, the flower of which consists of six very long lancedolate petals; and its fruit an ovate-oblong trilocular capsule, containing several roundish and compressed seeds. There are six species.

W.

W, or w, is the twenty-first letter of our alphabet.

WACHENDORFIA, a genus of plants of the class tracheides, or order monogynia; and arranged in Linnæus's natural method of classification under the 6th order, esnata. The corolla is hexapetalous, unequal, and situated below the germen; the capsule trilocular and superior. There are five species, none of which are natives of Britain.

WACKEN, a mineral that occurs in mass; sometimes it forms strata, but more frequently it runs in veins. Colour dark greenish-grey, which often passes to mountian-green, or blackish-green. Specific gravity from 2.6 to 3.0. Easily melts before the blowpipe. Liable to spontaneous decomposition.

WAD, or Wadding, in gunnery, a stopper of paper, hay, straw, old rope, yarn, or tow, rolled firmly up like a ball, or a short cylinder, and forced into a gun upon the powder to keep it close in the chamber; or, but up close to the shot, to keep it from rolling out, as well as, according to some, to prevent the inflamed powder from diluting round the sides of the ball, by its ignition, as it passes along the cluse, which it was thought would much diminish the effort of the powder. But, from the accurate experiments lately made at Woolwich, it has not been found to have any such effect.

WAGERS, or Sealing-Wagers, are made thus: Take very fine flour, mix it with white of eggs, isinglass, and a little yeast; mingle the materials; beat them well together; spread, the batter being made thin with gum-water, on even tin plates, and dry them in a stove; then cut them out for use.

You may make them of what colours you please, by ting the paste with brazil or vermilion for red; indigo or verditer, &c. for blue; saffron, tumeric, or gamboge, &c. for yellow.

WAGER OF LAW, is a particular mode of proceeding, whereby in an action of debt brought upon a simple contract between the parties, without any deed or record, the defendant may discharge himself by swearing in court in the presence of compurgators, that he owes the plaintiff nothing, in manner and form as he has declared, and his compurgators swear that they believe what he says is true. And this waving his law, is sometimes called making his law. 5 Bac. Abr. 428.

It being at length considered, that this waving of law offered too great a temptation to perjury, by degrees new remedies were devised, and new forms of action introduced, wherein no defendant is at liberty to wave his law.

Instead of an action of debt upon a simple contract, an action is now brought for the breach of a promise, or assumpsit; wherein though the specific debt cannot be recovered, yet damages may, equivalent to the specific debt; and this being an action of trespass, no law can be waged therein. So instead of an action of delinit to recover the very thing detained, an action of trespass upon the case, in trover and conversion, is usually brought, wherein though the specific thing cannot be had, yet the defendant shall pay damages for the conversion equal to the value thereof; and for this trespass also no wager of law is allowed. In the place of accounts, a bill in equity is usually filed, wherein, though the defendant answers upon his oath, yet such oath is not conclusive to the plaintiff, but he may prove every article, by other evidence, in contradiction to what the defendant has sworn. So that wager of law is now quite out of use, being avoided by the mode of bringing the action, but still is not out of force. And therefore when a new statute inflicts a penalty, and gives an action of debt, it is usual to add that no wager of law will be allowed.

WAGERS. In general a wager may be considered as legal, if it is not an incitement to a breach of the peace, or to immorality; or if it does not affect the feelings or interest of a third person, or expose him to ridicule: or if it is not against sound policy. 2 Durnel, & East, 610. See Insurance.

WAGES, what is agreed upon by a master to be paid to a servant, or any other per-
son that he hires to do his business for him.

2 Lid. Abr. 677. See Master and Servant.

WAGTAIL, in ornithology. See Motacilla.

WAIFS, are goods which are stolen and wavel by a felon in his flight from those who pursue him, which are forfeited; and though wavel is generally spoken of goods stolen, yet if a man is pursued with hue and cry as a felon, and he flees and leaves his own goods, these will be forfeited as stolen goods; but they are properly fugitive's goods, and not forfeited till the contrary is proved, and otherwise of record, that he fled for the felony.

2 Law. 430. See Estrays.

WAINAGE. The reasonableness of fines or amencements having been regulated by Magna Charta, that no person shall have a larger amencement imposed upon him than his circumstances or personal estate will bear, it is added, saving to the freethread his contem- ent or land; to the trader his merchandise; and to the countryman, wainage, or team and instruments of husbandry. 4 Black. 379.

WAIVER, in law, signifies the passing by of a thing, or a refusal to accept it; sometimes it is applied to an estate, or something conveyed to a man, and sometimes to a gift, &c. And a waiver or disagreement as to goods and chattels, in case of a gift, will be effectual.

Lit. 710.

WAKE, of a ship, is the smooth water asters when she is under sail: this shews the way she has gone in the sea, whereby the mariners judge what way she makes. For if the wake is right astern, they conclude she makes her way forwards; but if the wake is to leeward a point or two, then they conclude she fails to the leeward of her course. When one ship, giving chase to another, is got as far into the wind as she, and sails directly after her, they say she has got into her wake. A ship is said to stay to the weather of her wake, when in her staying she is so quick, that she does not fall to leeward upon a tack; but that when she is tacked, her wake is to the leeward; and it is a sign she feels her helm very little, and the steering of the ship.

WALE, or WARE, in a ship, those outermost timbers in a ship's side on which the sailors set their feet in climbing up. They are reckoned from the water, and are called her first, second, and third wale, or bend. See Ship.

WALES. By stat. 27 H. VIII. c. 26, and other subsequent statutes, the dominion of Wales shall be incorporated with, and be part of, the realm of England; and all persons born in Wales shall enjoy all liberties and privileges as the subjects in England do. And the lands in Wales shall be inheritable after the English tenure, and not after any Welsh laws or customs. And the proceedings in all the law-courts shall be in the English tongue. A session is also to be held twice a year in every county, by judges appointed by the king, to be held on the great sessions of the several counties in Wales; in which all pleas of real and personal actions shall be held, with the same form of process, and in as ample manner, as in the court of common-pleas at Westminster; and all the errors, unless otherwise directed by the court of king's-bench at Westminster. But the ordinary original writs, or process of the king's courts, do not run into the principality of Wales, though process of execution does, as also all prerogative writs, as writs of certiorari, quo warranto, mandamus, and the like, 3 Blac. 99.

Murders and felonies in any part of Wales may be tried in the next adjoining English county; the judges of assize having a concur- rent jurisdiction throughout all Wales, with the justice of the great sessions. Str. 255.

All local matters arising in Wales, capable of being tried in the king's-bench, are by the common law to be tried by a jury returned from the next adjoining county in England. Burt. 859. Where a man or master in Wales shall, upon any process out of the courts at Westminster, hold any person to special bail, unless the cause of action is twenty pounds or upwards. 11 and 12 W. c. 25.

WALK. See Gardening.

WALKERIA, a genus of plants of the class and order pentandria monogynia. The calyx is five-parted, inferior; corolla five-petalled; drupes five, one-seeded; nut ripe in a tree of the East Indies.

WALL, in gardening. Of all materials for building walls for fruit-trees, brick is the best, it being not only the handsomest, but the most lasting, and the most sanitory; and affording the best convenience for nailing, as smaller nails will serve in brick than will in stone walls, where the joints are larger; and if the walls are capped with fine-stone, and stone piles or columns at proper dis- tances, to separate the trees, and break off the force of the winds; they are very beau- tiful, and the most profitable walls of any others. In some parts of England there are walls built both of brick and stone, which are found very commodious. The bricks of some places are not of themselves substantial enough for walls; and therefore some persons, that they might have walls both substantial and wholesome, have built these double, the outside being of stone, and the inside of brick; but there must be great care taken to bond the bricks well into the stone, otherwise they are very apt to separate one from the other, especially when frost comes after much wet.

There have been several trials made of walls built in different forms; some of them having been built side by side in angles or variously projecting more towards the north, to screen off the cold winds; but there has not as yet been any method which has succeeded near so well as that of making the walls straight, and building them upright. Where persons are willing to be at the expense in the building of their walls substantial, they will find it answer much better than those which are slightly built, not only in cost, but in warmth; therefore a wall two bricks thick will be found to answer better than that of one brick and a half. The best aspect for ripen- ing fruit is south, with a point to the east; and the next best is south-west. It is a great improvement to have a trellis of wood against the wall, to train the trees to, as it prevents the wall being spoiled by nails, &c.

WALLENIA, a genus of plants of the class and order penicillaria monogynia. The calyx is four-leaved, the corolla has four pe- rsids, and the capsule is linear and birot- rated. There are four species, none of which are natives of Britain.

WAPENTAKE. See Judg. 777.

WAPENTAKE, from the Saxons, the same with what we call a hundred, and more especially used in the northern counties be- yond the river Trent. There have been several conjectures as to the original of the word, one of which is, that antitypically musters were made of the armour and weapons of the inhabitants of every hundred; and from those that could not find sufficient they deprived their good behaviour, their weapons were taken away, and given to others: whence it is said this word is derived. See Hundred.

WAR. The too frequent recurrence of this great and detestable calamity, unfortu- nately renders a definition of the word unnecessary. If we were called upon to define it, we should say, it is the wanton destruction, the cold-blooded slaughter, of the human race; we should call it the fruit of every sin that degrades and villifies mankind: we should mark it as a practice that diffuses misery and perpetuates vice: we should say, that if there is a barlesque upon the boasted reason of man it is this: when millions meet to murder each other for a quarrel in which, in general, they have not individually the smallest interest. The poet who wrote,

"One murder makes a villain, millions a hero," &c.

deserves a statue of gold; and the writer of that verse may sit high upon his chair, and profess to reduce the civilized world under one system of general despotism, and to plunder the property of unoffending nations and individuals, in the same manner as the highwayman, who by the laws of every well regulated community, for such an offence destined to the rope. We leave our readers to make the application to the present cir- cumstances of Europe, and we think they cannot long be at a loss.

In this view, as a means of defence, and as useful to the understanding of history, and not as giving our sanction to an irrational and antichristian practice, we insert the following article.

WAR, art of. As war, on the one hand, in respect to its effects, is intimately connected with the propriety and independence of nations; so, on the other, it requires infinite skill, combination, and management, when
considered as an art. Its principles, founded on the sciences themselves, are fixed and certain; but these branch out into such a prodigious variety of ramifications, that men of extraordinary talents and genius only have been able to excel in it.

As two different elements constitute the theatre of its operations, war is naturally divided into naval and military arrangements.

Of naval warfare.

The art of arranging squadrons or fleets in order of battle, and regulating their movements in such a manner as may be deemed best calculated for attacking, defending, or retreating, to the greatest possible advantage, is termed naval tactics.

The ancients seem to have excelled rather in land, than in sea engagements. On re-turning to the history of remote periods, we are perpetually reminded of the state of savage nations at the present day; the canoes indeed of the Trojans would have availed but little; yet the war-boats of Odysseus might not then have appeared contemptible. The Mediterranean was the early scene of naval exploits; and galleys were the vessels originally employed in these campaigns. These were propelled by the force of oars; and the combats being made to approach, and sometimes to board each other by means of flying bridges, a battle at sea differed but little from a battle on land. But as progress of time, a superiority was attempted to be obtained by means of skill and management. The prows were armed with brazen spigot, or tridents, which were so contrived as to pierce the enemy's vessel under water, and by letting in the sea, expose them to the danger of sinking. Turrets were also erected between the poop and the forecastle, for the purpose of overlooking the foe, and annoying him by means of darts and slings. In process of time, other improvements took place, which we shall here endeavour briefly to enumerate.

The dolphin, which was a huge and massive piece of lead, formed into the shape of the fish from which it had derived its name. This being perfectly water-proof by blackening, and ropes from the mast-head or yard-arm, was allowed to drop, whenever an opportunity presented itself; and penetrating through the keel of a vessel slightly constructed, it of course, by its own specific gravity, made a passage for the entering waves; and thus sometimes rendered even a retreat impossible.

2. Another engine in use, consisted of a scythe of iron, fixed at the top of a long pole; and was employed for the purpose of cutting asunder the slings of the sail-yards, so as to incommode them during action, and prevent escape from the decks.

3. Spears, or maces, of an extraordinary length, were constructed so as to annoy at a considerable distance; and thus, although stationary, to serve the purpose of a missile weapon.

4. The naval battering-ram, mentioned by Vergilus, consisted of a long beam, armed with a head of iron; and being suspended to the main-mast, was employed to good effect against the galleys.

5. A grappling-iron, which seized hold of any part of the opposing vessel, and facilitated the boarding of her.

6. The last, and most formidable of all their machines, was the balista; by which large stones could be thrown to a great distance, with a considerable degree of certainty, and the most terrible effects.

Having thus mentioned the engines made use of by the ancients, we come next to the disposition of their fleets. It was then, as now, considered a great advantage to obtain the weather-gage; and it was at the same time endeavoured to contrive so as to have the gun behind themselves, while it shone directly in the faces of their enemies. Instead of manoeuvring by means of their sails, these were always lowered previously to action; and the prows being presented to the enemy, they advanced against each other by force of oars, and amidst the sound of trumpets. After expending their arrows and javelins, recorse was at length had to the sword, so that courage alone decided the combat.

The code of signals, like the symbol by which they were regulated, was simple in the extreme. It consisted sometimes of a gilded shield, and sometimes of a red garment, or banner. During the elevation of this, the battle commenced without ceremony. During one memorable sea-fight, the galleys of the Romans were ranged so as to represent a wedge in front, while the Carthaginians drew up their fleet in such a manner as to form a rectangle on two sides of a square, to derive the purpose of annoying and inclosing the flank of the enemy; the former was the figure best calculated for attack, the latter for defence.

Notwithstanding the boasted greatness of the Roman people, yet when this country was invaded by Cesar, they appear to have obtained but little eminence in respect to naval affairs. A fleet on that occasion was not brought from the mouth of the Tiber, and the vessels built by Scipio exhibited nothing formidable or ingenious either in their management or construction. They must have been small and contemptible, in point of size, for they were drawn up on the beach, near to the town of Lucca, now vanished, and fortified like the camp, by means of a ditch and rampart.

On the departure of these invaders, who, as usual, at once conquered and civilized the barbarous tribes among whom they settled, the situation of the Britons must have been truly distressing. Reduced perhaps to the use of the coracles, or boats made of skins stretched on oisters, they were able to derive little or no benefit from the ocean that surrounded them.

On the neighbouring continent, however, the boats had made a greater progress, or at least left a deeper impression; for, doubtless, the keels of the Saxons must have appeared formidable to men whose vessels were ribbed with two or three timbers.

The wars with the Danes rendered some attention to maritime affairs necessary; and Alfred is represented as having encouraged and employed foreign artificers and masons, by means of bonds or constructed vessels of a superior size. With these he secured many of the northern coasts, which were then infested by pirates, freebooters, and enemies of all sorts: and this prince appears to have rescued his subjects from the incursions of pirates.

At length the depredations of the northern states became so formidable, from being occasional visitors, for the sake of plunder, the Danes, and other nations bordering on the Baltic, began to think of settling in Britain, and in consequence of their power and numbers, they were finally enabled to place one of their own sovereigns on the throne. After this, either by land or sea, all contention necessarily ceased.

William the Norman obtained the crown by the gross management of Harold, in respect to both naval and military affairs; for on one hand he had detached his squadron to the northern parts of the kingdom, instead of keeping it on the southern shore to oppose the enemy, while on the other he put his whole stake to hazard on a single battle. The fleet conducted by the Conqueror to the coast of Sussex, (Sept. 28, 1066) consisted of no less than three hundred vessels; but they appear to have been contemptible in point of size, and to have been but ill calculated to cope with an enemy.

A long interval succeeded before any great progress, in respect to maritime affairs, occurred; and when the Seine were between the kings and the bishops, the acquisition of Ireland, and the incorporation of Wales, all took place before the foundation of a national navy was laid. But commerce, the true nurse of sailors and of a fleet, began to be attended to; trade was no longer carried on solely by foreigners; while the wool of England, after being woven and spun where it had grown, was exported to distant countries, and brought back profitable returns. The ships of the cinque-parts now became formidable; they were regularly wont out, when required, to the kings of England; and assisted not only in their wars, but in the conveyance of their troops to the continent.

In 1217, Hubert de Burgh, governor of Dover-castle, after obtaining the weather-gage, defeated the French, in the first seafight that ever took place between the English and the Continent.

It was not until the time of Edward I., however, that any great expeditions seem to have taken place. That prince fitted out three squadrons at the same time.

In 1340, the English fleet appears to have been drawn up in the straight lines, the larger ships being placed in the front, and the smaller in the rear, whence they were enabled to send fresh supplies of men, or otherwise grant their assistance, as occasion might serve. In this battle, which took place on the coast of Flanders, the French lost two hundred and thirty ships, and had two of their admirals slain. During the contest for the crown of France, the arms of England were eminently triumphant both by sea and land; but the wars between the rival houses of York and Lancaster so completely occupied the hands and the hearts of the nation, as to prevent any attention to foreign affairs.

At length HEN VIII. a wise and able prince, began to build ships of war, one of which cost him upwards of 14000L. His son, Henry VIII. notwithstanding those odious vices and follies before mentioned, seems to have conceived a just notion of the true interests of the nation, in respect to maritime
affairs. He accordingly instituted the navy-office, appointed commissioners, constructed several large ships, and laid the foundations for naval discipline and drill, in the time of his daughter, preserved the independence, and added not a little to the glory, of England.

Nor were the French at this period inactive to their navy. During an engagement with the English in the Channel, their fleet appears to have assumed a regular and systematical arrangement. It consisted of three divisions, that in the centre being composed of thirty-six ships, and the van and rear of thirty each. The galleys, which had come from the Mediterranean, were considered in the same point of view as frigates are at the present day, and never entered the line of battle.

Meanwhile, the introduction of gunpowder had created an entire change in the weapons of war; and at this day the sword and the boarding-pike are perhaps the only ones that have been in use, both by the ancients and moderns. The Spaniards, who had become a great maritime nation, said to have gone even to sea mainly to procure cannon, during a sea-fight with the English and their allies, off Rochelle, in 1372: yet it has been asserted, that this instrument of destruction was actually recurved to by our ancestors in 1350. The galleys then, which had been threatened by a heavy invasion, means of an armada, which, whether we consider the size of the vessels, or the manner in which they were manned and equipped, must be considered as formidable. They entered the Channel in the form of a crescent, the horns of which extended to a prodigious distance, and were assuredly more than a match for any force that could be brought to oppose them. But lord Howard of Effingham, assisted by Drake, Hawkins, and Froebisher, (all of whom, but himself alone, had been bred in the merchant-service), so managed an inferior squadron, as to obtain a complete victory.

A competent idea may be formed of the fleet of England in those days, by observing, that on the demise of Elizabeth, it consisted of forty small ships only, of which number four did not exceed forty guns, but two of those were mere frigates. They were commanded by twenty-two commodores, or twenty-three others were below-five hundred; of the rest, some did not exceed fifty, and some not even twenty, while the whole number of guns amounted to no more than 774.

But the long and bloody contest that afterwards took place with Holland for naval superiority, finally fixed the character of the English nation, in respect to maritime affairs. During three dreadful wars, there were no less than nineteen general engagements, in one of which Nelson was victorious. Every resolution had its effect, and the English were never defeated. Their navy was renewed for three years in succession, in another for two days, and in a third for one; making in all no less than twenty-five days of general actions. What is still more remarkable, during the whole period, the enemy's fleet, D. W. Van. 5.

At the battle of the Nile, Charles II. the royal navy amounted in all to 113 sail. James II. while a subject, had commanded a fleet, and insti-

WAR.

tuted, or rather improved and enlarged, the system of signals. At his abdication, England possessed 173 vessels of different descriptions. During the time of William and Mary, these were increased to 320; but their success was not proportionable to the public expense, and it was not till the reign of Anne, however, that the naval power of France received a deadly blow at Vigo, having lost no less than seventeen ships of war.

On the accession of the house of Brunswick, the fleet increased rapidly; and during the present reign, it has obtained an unprecedented degree of prosperity: for towards the middle of the year 1806, it consisted of 132 sail of the line, 17 forty-four and fifty gun ships, 190 frigates, 160 sloops, &c. and 242 gunboats, forming a total of 753 in commission.

After these observations on the rise and progress of the British navy, it may be necessary to make some remarks on the manner in which it is conducted during action. As the skill and bravery of our seamen have always been eminent by comparison in close engagements between single ships, it necessarily follows, that the adoption of any system which would place the crews of all the vessels in the same condition, could not fail to be attended with the most beneficial advantages. It was a long while, however, before this could be effected; for the opposite squadrons being usually disposed in right lines parallel to each other, every ship had to suc-ceed to a wind on the same tack, it necessarily fol-

lowed, that the action in general, provided equal numbers were brought into contact, could neither be long nor decisive. Thus it frequently happened, that nothing decisive occurred, not so much as a single ship being lost or won on either side.

A great and sudden change was however effected. This occurred on the 12th of April 1782, when admiral sir George Rodney, instead of following the old system, pierced the French line, formed by the count De Grasse, and gained a complete victory. The same occurred under lord Howe, June 1, 1794.

A similar principle, viz. "the directing the principal share of the force of a fleet against a few ships," was put in practice by sir John Jervis, now earl St. Vincent, on the 13th of February, 1797.

At the battle of the Nile admiral sir Horatio, afterwards lord viscount Nelson, contrived to double down on the enemy, and place part of their fleet between two fires: while during that of Trafalgar he advanced in two lines, and effected a junction with this similar effect, but by different means. The latter, indeed, was exactly the same in all: that of bringing fleets into the same position as single ships, so that the sailors might be enabled to fight hand to hand, with the additional advantage, that the many would thus be enabled to attack the few.

It has already been observed, that some of our gallant naval commanders, during the civil wars, had been bred in the army; and it is not a little remarkable, that the great change which has taken place in the line of late years, in respect to the management of fleets, appears to have originated with a landsman, who, according to his own account, had attained ten years of age, before he had ever seen a ship. The gentleman to whom we now allude is Mr. Clerk, or Elsin, author of an "Essay on Naval Tactics, Systematical and Historical, in four parts." The first edition of the first part appeared in 1789, and the second edition in 1794; and it is the last in that language that we shall here take some notice of it.

During the American war, the action between amphibial Keppe and the French fleet, on the 27th of July, 1779, engaged Mr. Clerc's particular attention. The idea of the line of battle was in some parts novel, as it was an attack from the leeward; and he remarked, with surprise, that in the course of the two long trials which followed this indecisive fight, as well as that of admiral Matthews, in 1744, and of admiral Byng, in 1756, not a single hint escaped, "that it was possible any thing defective could be attributed to the system of the attack itself, or that any kind of improvement should be attempted," such as the scheme since put in practice, "the cutting the enemy's line asunder; the directing the greater part of the force of a fleet against a few ships, either in the van or rear of the enemy, in the same manner as by a hawking, or a plover-sailing or crippled ships of the enemy."

During the engagement of admiral Byron off the island of Grenada, on the 7th of July, 1779, the attack, like those made by Matthews and Byng, was from the windward; and from a consideration of all these cases, Mr. Clerk became induced to think, that the want of success was not to be attributed either to any abatement in the spirit of the seamen, or by any fault in the ship-building; but solely to the unskilful manner in which the general attacks were conducted.

Impressed with these ideas, he mentioned his suspicions, in January 1780, to a friend of sir George Rodney, to whom he at the same time communicated his theories of attack, from both windward and leeward, and explained his doctrine of cutting the enemy's line. The propriety of these plans was not fully exemplified however, until two years after, (April 12, 1782;) when a victory, far more decisive and important than any which had been gained by our fleets during the last century, was obtained; for, on this occasion, the attack was from the windward; and from the author considers as more rare, ingenious, and effectual, than an attack from the windward; in addition to which, the enemy's line was at the same time cut in two.

In the Essay on Naval Tactics, the importance of a single ship to windward bearing down directly on an enemy to leeward, is pointed out by a diagram, accompanied with a demonstration, we are here presented with a complete and effectual way of cutting directly against the rigging of a ship, with its result when employed against the bull. In respect to fleets, an attack from the windward is supposed to be attended with a disadvantage in the ratio of twenty to one, as the fire of the whole line to leeward can be applied, on such an occasion, against the van of the assaulting; a manoeuvre which the French were well acquainted with, and put constant in practice, until the new mode of combat was introduced.

These positions are illustrated by:

1. Admiral Matthews' engagement with the combined fleets of France and Spain, off Toulon, February 11, 1744.
WAR.

2. Admiral Byron's action with the French fleet off Minorca, May 20, 1756.
4. Admiral Byron's off Grenada, July 6, 1779.
5. Admiral Barrington's, at St. Lucia.
6. Sir George Bridges Rodney's, off Cape Finisterre and St. Vincent.

The art of arranging armies in order of battle, and of regulating their movements in such a manner, as may be deemed most proper for attacking, defending, or retreating, to the greatest possible advantage, is termed military tactics. It has been generally recognized, and at length received as an axiom, that there is no branch of human knowledge more difficult than that of which we are now about to treat; and both ancient and modern have been well convinced of this fact, that it has been regularly taught in public schools, erected expressly for that purpose.

Two celebrated nations, the Greeks and the Romans, were particularly anxious to attain perfection in the science of war; and this account, in order to describe their extraordinary success, when combating against enemies who, content with a blind obedience to a custom, placed their chief confidence not in the discipline, but in the multitude of their combatants, the circumstances on the contrary were conspicuous that the strength of armies consists principally in the art with which they are managed, and the principles by which they are regulated; that multitudes are often more embarrassed than system, and that a small body of troops, well regulated, and ably directed, is capable of overcoming a large one, deficient in respect to those advantages. Therefore, they deduced a theory relative to the disposition of their soldiers, the order of battle, the manner of encamping, the best and most regular mode of marching, of forming, and of acting, in such a way, as to oppose the strong to the weak, while they at the same time anticipate all the stratagems, and prevented all the deceptions, of the enemy. On the other hand, they did not forget to regulate the different species of arms, and to adapt the army to the nature and exigencies of the moment, and to adopt the most advantageous method of using them, whether offensively or defensively.

War, accordingly, was regarded as an art, of which it was necessary to become acquainted with the principles anterior to the practice. It is but little wonder, therefore, that so many great men were produced, and such wonderful effects ensured; more especially in Greece, where infinite pains were taken to attain a perfect knowledge of the art, and the Romans too directed their attention to military affairs; and the order of the legion was supposed to be placed on the whole to be superior to that of the phalanx. Vegetius, indeed, after examining its formation, explains that none but a God could have contrived such a powerful and admirable assemblage.

That wonderful nation too, laying prejudice aside, was examined, studied, and adopted, those practices of war they were excelled by their enemies. A defeat was never lost on them; for after every reverse, they obtained an increase of their military knowledge. Thus the sharp-edged weapons of the Gauls, and the elephants of Pyrrhus, never surprised them but once; and they had not sooner become acquainted with the Spanish sword, than they immediately abancon their own. At the same time, they did not omit to employ Numidian horses, Cretan archers, slingers from the Balearic islands, and ships belonging to Rhodes. In fine, no people ever exercised with such prudence in their preparations for a campaign, or carried on hostilities with such extraordinary ability. We are the less inclined to wonder, therefore, at the observation of Josephus, who remarks, that with them was a meditation, and pace an exercise.

We accordingly find that they abound with great commanders; and what is still more extraordinary, that many of these commanders proved victorious without the benefit of experience. Some, at the age of twenty-seven, knew how to repair the faults committed by his father and his uncle, in consequence of previous study. When Lucullus marched into Asia for the purpose of attack, he instructed himself, according to Cicero, and read into the works of the best authors; while at a later period, Nurse, who had never before commanded, nor even served, replaced Belisarius, over and over, and successfully concluded the struggle with the Goths.

It is evident, therefore, that war is to be regulated according to certain rules and principles; and that on the knowledge and application of these, depends the fate of a campaign, and perhaps of a nation. It necessarily follows, that a general ought to possess extraordinary talents and attainments. According to a celebrated author, "some qualities should be born with, and others acquired by him." In addition to these, he should also possess a quick eye, so as to enable him to judge of an advantageous position for his troops, decide on a manoeuvre to be made or to be avoided, of a country suitable or unsuitable to his army, and, above all, of a field of battle where he should give the greatest number of possible advantages at the least possible risk or inconvenience.

He should at the same time exhibit a sound and solid judgment; for the choice of officers to be put at any particular exigency, depends in a great measure upon him, and therefore the best dispositions would prove fruitless if not ably seconded. As his orders too cannot, from the nature of things, be precise, it is expected therefore of those who command under him, to know how to take advantage of a wrong movement on the part of the enemy, to commence an attack themselves, or only to sustain the troops engaged, and to vary their conduct according to the varying nature of circumstances.

But these qualities in the chief without subordination on the part of those who are subject to his command would be of little avail, if order and discipline were not duly maintained. Without these, the most numerous and best-composed army would soon become little better than a horde of Tartars, who, being united only by the hope of booty, separate as soon as that motive ceases to operate. Great as it is necessary, however, in enforcing discipline, and in any mean ought to be adopted. Too much severity disgusts the soldier, and not unfrequently
PRODUCES ANTIQUITY; TOO MUCH INDULGENCE ON THE OTHER-HAND SINKS HIM INTO IDIOLATRY, AND INDUCES HIM TO NEGLECT HIS DUTY; LICENCIATENESS MAKES GOOD ORDER APPEAR BASHERFUL; AND GOOD GOVERNMENT LIBERATES HIS SOUL FROM ALL CONSIDERATION, IN HIS SUPERIOR OFFICER, SO THAT THE MOST FATAL RESULTS ARE AT LENGTH UNAVOIDABLE.

BEHIND THE ABOVE QUALITIES, WHICH ARE SO ESSENTIAL, AND EVEN NECESSARY, IN A COMMANDER, A GENERAL WHO WOULD ASSUME THE TITLE OF A HERO, OUGHT TO UNITE IN HIMSELF, NOT ONLY ALL MILITARY, BUT ALL CIVIL AND POLITICAL EXCELLENCE. IT IS A KNOWLEDGE OF THE LAWS, CUSTOMS, CONSTITUTIONS, PRODUCE, AND NATURE OF DIFFERENT STATES, THAT HE IS TO REGULATE HIS OPERATIONS, AND MAKE WAR WITH SUCCESS. NOTHING WILL ESCAPE HIM, BECAUSE EVERY THING IS ESSENTIAL TO HIS PROJECTS; THE GENIUS OF THE COUNTRY POINTS OUT THE MANNER OF HIS MARCHES AND HIS MOVEMENTS, AND THE KNOWLEDGE OF THE INHABITANTS WILL LEAD HIM TO ANTICIPATE WHATEVER MAY BE EXPECTED ON THEIR PART. ONE NATION IS VENEREABLE, FIERCE, AND FORMIDABLE, AT THE FIRST ONSET; ANOTHER IS NOT SO HERETICALLY; THE ONE STANDS SOLELY WITH THE FEMALE, THE OTHER WITH THE FEMALE, A SINGLE INSTANT DETERMINES SUCCESS; WITH THE LATTER, THE ACTION IS NOT SO RAPID, BUT THE EVENT IS LESS DOUBTFUL.

IN FORMER TIMES, THE ART OF WAR WAS DIFFERENT FROM WHAT IT IS AT PRESENT; THE GENERAL PRINCIPLES ARE ALIKE. AFTER THE DARTS, JAVELINS, AND ARROWS HAD BEEN EXPENDED, THE COMBAT TOOK PLACE BETWEEN OPPONENTS WHO ENGAGED HAND TO HAND; AND THEY DID NOT DIFFER FROM ONE ANOTHER, THE CROSS-BOWS HAVING ALL OPERATING BY MEANS OF THE IMPETUS, THE ACTION WAS GENERALLY LONG AND BLOODY. SOME OF THE PLANS OF BATTLE WERE EXACTLY THE SAME AS THEY ARE NOW; AND IT IS NOT A LITTLE REMARKABLE, THAT Cesar, At Pharsalia, DREW UP HIS TROPS ACCORDING TO THE OBVIOUS ORDER, WHILE EPIANONIADAS AT LEUCRA ADAPTED THAT WHICH, ON ACCOUNT OF ITS PARTICULAR FORM, IS CALLED AN ECHELON ATTACK.

IN THE MIDDLE AGES, WAR APPEARS TO HAVE DEGENERATED INTO A SYSTEM OF MARAUDING, BEING CARRIED ON NEARLY IN THE SAME MANNER AS AMONG THE MAHRATTAS AT THE PRESENT DAY. THE TROOPS, IF THEY WERE NOT ARMED, WERE MOUNTED ON HORSEBACK; AND THE MEN WERE CARRIED IN ARMOUR, PLACED THEIR GLORY IN STANDING ERCENT IN THEIR SIRUPPS, SO AS TO RESIST THE SHOCK OF AN ADVERSARY. AT LENGTH, DURING THE CRUSADES, A MORE REGULAR SYSTEM BEGAN TO PREVAIL; AND THE CHRISTIANS ON THE PLAINS OF PONTUS, MET WITH A MASTER IN THE ART OF WAR, IN THE PERSON OF SALADIN.

AT THE BATTLE OF HASTINGS, THE NORMAN CROSS-BOWS UPON TO HAVE GAINED AND EVEN TO HAVE SURPASSED THE ENGLISH, WHOSE RANKS WERE CLOSE, AND WHOSE LINE COULD NOT BE PIERCED. ON PERCEIVING THIS, WILLIAM HAD RE COURSE TO STRATEGEM, AND CONQUERED BY PRETENDING TO FLY, FOR HE KNEW THAT REGULAR ORDER COULDN'T NOT BE PRESERVED IN A PERSUASION; AND HE WAS THUS ENABLED TO OVERCOME AN ENEMY WHICH HAD BEEN THROWN INTO DISORDER.

THE INTRODUCTION OF GUNPOWDER HAS MADE A GREAT CHANGE IN THE ART, WITHOUT ALTURING; HOWEVER, ANY OF ITS GENERAL PRINCIPLES, WHICH WERE EXACTLY THE SAME AT THE BATTLES OF CANNE AND OF AUSTRIA. THIS INVENTION, HOWEVER, HAS MADE MODERN WARS INFINITELY MORE EXPENSIVE, AND MORE DIFFICULT, IN RESPECT TO THEIR MANAGEMENT. AN IMMENSE QUANTITY OF BAGGAGE, AMMUNITION, AND ARTILLERY, HAS NOW BECOME NECESSARY, AND THE SPECIFIC NUMBER RATHER THAN THE INTEGRAL ALLOWS THE ROYAL ARMS TO THE SOLDIER, IS ATTENDED TO. AS MUCH DEPENDS ON THE SYSTEM, ON THE REGULAR SUPPLY OF PROVISIONS, FOR MEN AND HORSES, A PLAN OF THE CAMPAIGN IS FORMED IN ADVANCE; FORTRESSES ARE CONSIDERED AS SO MANY FACTORIES, AND THE MAGAZINES ARE MAINTAINED UNDER THEIR PROTECTION, AS THEY ARE THE BASIS WHERE THE LINES OF OPERATION ARE TO BE TRACED. IT IS, THEREFORE, THAT STRONG PLACES SUCE TO EQUALLY PROTECT RETREATS, AND TO ADVANCE HAVENS.

IN ANCIENT TIMES, IT WAS USUAL TO ASSAULT THE ENEMY IN FRONT, BUT IT IS NOW CUSTOMARY TO ACT ON THE FLANKS AND THE REAR, TO CUT OFF CONVOYS, AND TO ANNihilate SUPPLIES, TO DESTROY THE RESOURCES ON WHICH HE DEPENDS. IT IS USUAL, THEREFORE, INSTEAD OF ASSUMING A POSITION DIRECTLY IN FRONT, TO OCCUPY A CAMP EITHER TO THE RIGHT OR TO THE LEFT; FOR THE CENTRE, WHICH IS THE STRONGEST PART OF THE LINE, IS ALMOST HAPPLY ELUDED. WHILE ON THE CONTRARY, THE ARMS WHICH ARE NECESSARY IN THE WEAK PORTION, THEN BECAME EXPOSED TO INFLICT.

IT WAS ABOUT THIS PERIOD, THAT IN CONSEQUENCE OF THE FREQUENCY OF SIEGES, THE PIGE BECAME ESSENTIAL TO THE ADVANCE OF THE ARMY; THE BAYONET ADOPTED. THE PRINCE DE Dessaoue SOON AFTER INTRODUCED THREE IMPORTANT CHANGES, TO TWO OF WHICH THE PRUSSIANS WERE INDUCED FOR THE BATTLE OF MOSVITZ. THE FIRST OF THESE, THAT OF BEARING, THE SECOND NOT TO REND THE FIRE OF MUSQUETERY MORE FATAL, AND THUS SERVE TO EXHIBIT IT FROM THE CONTEMPT IN WHICH IT WAS HELD BY THE CHEVALIER POLARD AND MARSHAL SACE. THE SECOND WAS THE EQUAL STEEP, WHICH ENABLED THE WHOLE LINE IN REGULAR MOVEMENTS TO PERFORM A CHARGE IN THE ORDER OF BATTLE, WHICH WAS ALTERED TO CONSIDER THREE INSTEAD OF FOUR LINES.

IT WAS ON THESE FOUNDATIONS THAT FREDERICK II. ERECTED A GRAND SUPERSTRUCTURE. IT WAS HE WHO, IN ADDITION TO THE PRACTICE OF THESE IMPROVEMENTS, INTRODUCED ORDER INTO THE MOVEMENTS OF THE INFANTRY, AND EFFECTED AN ENTIRE CHANGE IN THE CHARGE OF THE CAVALRY; BEFORE HIS TIME THE TROOPES NEVER ADVANCED WITH A QUICKER PACE THAN A TROT, AND HAD RECURS TO FIRE-ARMS INSTEAD OF THE SABRE.

AFTER ALL, ALTHOUGH WAR AS A SCIENCE HAS LATELY BEEN CERTAINLY CARRIED TO A GREAT DEGREE OF PERFECTION, YET IT HAS VARIED BUT LITTLE IN ITS PRINCIPLES; ON THE CONTRARY, THE MAXIMUM OF THE ART SEEMS NOW TO BE TO BRING TROOPS TO ATTACK WITH THE BAYONET, AND TO KEEP THE WAR OF THE SUCCESSION, WHICH BECAME TO DO WITH THE PIGE SOME CENTURIES AGO; AND THE ENGLISH BY THEIR CONDUCT IN FLANDERS, EGYPT, AND CALABRIA HAVE PROVED THAT TANG TO HAND THEY STILL PRESERVE THEIR ANTIENT REPUTATION AND NOVAE OF OLD, ARE UNQUEALED BY A CHARGE.
Meanwhile, military seminaries for the instruction of those destined to become officers have been established, able masters have been also provided, and the arts and sciences connected with war, are now publicly taught. By the institution of the volunteers, the genius of the nation has been of late years directed in an eminent degree to military affairs; and it seems now to be established as a principle, that an army has become to the full as necessary as a fleet, for the defence of our own islands, as well as the annoyance of the dominions of our enemies.

Before we conclude this subject, it may be necessary to enumerate a few of the principal events, laid down by those who have treated of the art of modern warfare; observing at the same time, that they apply rather to a continent than an island.

1. It is necessary to have magazines for the supply of an army, and fortresses for the protection of these supplies.

2. There should be a range of fortresses on the same line, to serve as a base for future operations.

3. To undertake with safety an offensive operation against the enemy, it is necessary that the two fortresses at the extremities of the line, should be separate at such a distance from each other, that the two lines of operations proceeding from them may meet at the given object, and form an angle of at least 90 degrees.

4. It is easier to stop the progress of an enemy by occupying a frontier on his flank, than in his front.

5. The best way of opposing an offensive operation, is to act offensively.

6. The subsistence of the enemy's army, rather than the army itself, ought to be the chief object against which operations are to be directed.

7. It is always possible to avoid a combat, by preventing the enemy from approaching too near.

8. A general ought never to wait an attack, but to put himself in movement to act offensively, even if in possession of a strong position.

9. The enemy can never be drawn up so as to prevent his flank from being turned.

10. The front opposed to the enemy ought to be extended so as to envelop him, and he may be enveloped by an inferior number, provided it is posted on his flanks.

11. The infantry ought to be constantly supported by the cavalry, and the best way of achieving this, is to draw up the latter in the rear.

12. A column is the best defensive figure that can be assumed against cavalry.

WARS. The following are the most remarkable wars in which this country has been engaged, since the

War with Scotland, 1068.

War with France, 1249.

Civil War, 1262—ended, 1267.

War with France, 1297—ended, 1327.

War with France, 1339.

War with France, 1358—ended, 1360.

War with France, 1378—ended, 1389.

War with France, 1400—ended, 1402.

War with France, 1403—ended, 1409.

War with France, 1410—ended, 1415.

War with France, 1422—ended, 1423.

War with France, 1427—ended, 1429.

War with France, 1462—ended, 1477.

War with France, 1486—ended, 1489.

War with France, 1502—ended, 1509.

War with France, 1527—ended, 1529.

War with France, 1532—ended, 1535.

War with France, 1557—ended, 1559.

War with France, 1564—ended, 1566.

War with France, 1576—ended, 1579.

War with France, 1597—ended, 1600.

War with France, 1607—ended, 1609.

War with France, 1629—ended, 1635.

War with France, 1648—ended, 1650.

War with France, 1667—ended, 1668.

War with France, 1677—ended, 1679.

War with France, 1689—ended, 1690.

War with France, 1697—ended, 1700.

War with France, 1702—ended, 1703.

War with France, 1713—ended, 1714.

War with France, 1726—ended, 1727.

War with France, 1727—ended, 1728.

War with France, 1733—ended, 1734.

War with France, 1735—ended, 1736.

War with France, 1737—ended, 1738.

War with France, 1739—ended, 1740.

War with France, 1741—ended, 1742.

War with France, 1743—ended, 1744.

War with France, 1745—ended, 1746.

War with France, 1747—ended, 1748.

War with France, 1749—ended, 1750.

War with France, 1751—ended, 1752.

War with France, 1753—ended, 1754.

War with France, 1755—ended, 1756.

War with France, 1757—ended, 1758.

War with France, 1759—ended, 1760.

War with France, 1761—ended, 1762.

War with France, 1763—ended, 1764.

War with France, 1765—ended, 1766.

War with France, 1767—ended, 1768.

War with France, 1769—ended, 1770.

War with France, 1771—ended, 1772.

War with France, 1773—ended, 1774.
The general, therefore, who is chosen for the command of an offensive army, should have wisdom, penetration, and foresight; wisdom, to preserve a proper discipline in his corps, that the allied prince may have no cause to complain of him; foresight and prudence, to prevent his troops from suffering for want of subsistence, or being exposed to the perils of war, but in proportion to their numbers with those of the allied prince; and finally, that nothing shall pass without his knowledge, which may be prejudicial to his master.

War, council of, is an assembly of great officers, called by a general, or commander, to deliberate with him on enterprises and attempts to be made. On some occasions, the quarter ports,under the governor of an assembly of officers, sitting in judgment on delinquent soldiers, deserters, coward officers, &c.

WARD, in law-books, a word of divers significations; thus, a ward in London, is a description of the charge of one of the aldermen of the city. There are twenty-six wards in London, which are as hundreds, and the parishes thereof as towns. A forest is divided into wards, and so are most of our hospitals.

WARDEN, one who has the charge or keeping of any person, or thing, by office. Such is the warden of the Fleet, the keeper of the Fleet-prison, who has the charge of the prisoners there, especially such as are committed from the court of chancery for contempt.

Warden, in an university, is the head of a college, answering to what in other colleges we call the master. Warden, or lord-warden, is the governor of these noted havens, who has the authority of an admiral, and sends out writs in his own name. Warden of the mint, is an officer whose business it is to receive the gold and silver bullion brought by the merchants to pay for them, and oversee the other officers. He is called keeper of the exchange and mint.

Warden, church. See Church-Warden.

WARDMOTE, in London, is a court so-called which is kept in every ward of the city, answering to the curates comitata in ancient Rome.

WARDS was a county first erected in the reign of Henry VIII, and afterwards augmented by him with the issue of livery; whence it was styled the court of wards and livery, but dissolved by 12 Car. II.

WARDSHIP. In our ancient customs, when the tenant died, and his heir was under the age of twenty-one being a male, or fourteen being a female, the lord was entitled to the wardship of the heir, and was called the guardian in chivalry. This wardship consisted in having the custody of the body and lands of such heir, without any account of the profits, till the age of twenty-one in males, and fourteen (which was afterwards advanced to sixteen) in females. For the fine supposed the heir male unable to perform knight's service till twenty-one; but as for the female, she was supposed capable at fourteen to marry, and then her husband might perform the office. 3 Black, 67. This privilege of the lord's was abolished under the Commonwealth, and the abolition confirmed by act; 12 C. 2. c. 24.

WARNING-WHEEL, in a clock, is the third or fourth, according to its distance from the first wheel. See Clockwork.

WARP, in the manufacture of threads, whether of silk, wool, linen, hemp, &c. that are extended lengthwise on the weaver's loom; and across which the workman by means of his shuttle passes the threads of the wool, to form a cloth, ribband, festoon, or other stuff.

For a woolen stuff to have the necessary qualities, it is required that the threads of the warp should be of the same kind of wool, and of the same fineness, throughout; that they are sized with Flanders or parchement-sizing, well prepared; and that they should be in sufficient number with regard to the breadth of the stuff to be wrought. To warp a ship is to shift her from one place to another, when the wind and tide will permit it without danger.

WARRANT, a prerequisite under seal and sign to some officer, to bring any offender before the person giving it. Warrants of commitment are issued by the privy council, a secretary of state, or justice of the peace, &c. where there has been a private information, or a witness has deposed against an offender. Wool's Inst. 614.

Any one under the degree of nobility may be arrested for a misdemeanor, or any thing done against the peace of the kingdom, by warrant from a justice of the peace; but if the person is a peer of the realm, he must be apprehended for a breach of the peace by warrant out of B. R. Dalt. Just. 203.

A constable ought not to execute a justice's warrant, where the warrant is unlawful, or the justice has no jurisdiction; if he does he may be punished. Ploed. 294.

But if any person abuses it, by throwing it in the dirt, &c. or refuses to execute a lawful warrant, it is a contempt of the king's process, and the offender may be indicted and fined. Crompt. 149.

A general warrant to apprehend all persons suspected, without naming or particularly describing any person in special, is illegal and void. As the duty of the magistrate, and ought not to be left to the officer, to judge of the ground of the suspicion. Also a warrant to apprehend all persons guilty of such a crime, is no legal warrant; for the point upon which its authority rests, is a fact to be decided on a subsequent trial; namely, whether the person apprehended (thereupon is guilty or not guilty. 4 Black, 29.)

A warrant may be lawfully granted by any justice for treason, felony, or praemunire, or any other offence against the peace; and it seems clear, that where a statute gives one justice a jurisdiction over any offence, or a power to require any person to do any thing ordained by such a statute, it implies gives a power to every such justice to make out a warrant to bring before him any one accused of such offence, or compelled to do any thing ordained by law; so it cannot but be intended, that a statute which gives a person jurisdiction over an offence, means also to give him the power incident to all courts, of compelling the party to come before him. 2 Hare, 84.
But in cases where the king is not a party, or where the corporal punishment is appointed, as in cases for servants' debts and the like, it seems that a summons is the more proper process; and for default of appearance, the justice may proceed; and so in actions for debt, the sheriff is often directed by special statutes.

A warrant from any of the justices of the peace, and of the like, it seems that a summons is the more proper process; and for default of appearance, the justice may proceed; and so in actions for debt, the sheriff is often directed by special statutes.

A warrant from any of the justices of the peace, and of the like, it seems that a summons is the more proper process; and for default of appearance, the justice may proceed; and so in actions for debt, the sheriff is often directed by special statutes.

A warrant from any of the justices of the peace, and of the like, it seems that a summons is the more proper process; and for default of appearance, the justice may proceed; and so in actions for debt, the sheriff is often directed by special statutes.

A warrant from any of the justices of the peace, and of the like, it seems that a summons is the more proper process; and for default of appearance, the justice may proceed; and so in actions for debt, the sheriff is often directed by special statutes.

A warrant from any of the justices of the peace, and of the like, it seems that a summons is the more proper process; and for default of appearance, the justice may proceed; and so in actions for debt, the sheriff is often directed by special statutes.
WATCH.

which is the small spring in new pocket-watches, underneath the balance. 5. The balance, whose parts are the verge, pallets, cocks, and the bob. 6. The wheels, which are the crown-wheel in pocket-pieces, and swing-wheel in pendulums, and the balance-wheel, etc. 7. The contrate-wheel, which is that next the crown-wheel, &c. and whose teeth and hoop lie contrary to those of other wheels, whence the name. 8. The great or first wheel, which is that of the fusee, &c. immediately drives; after which are the second wheel, third wheel, &c. 9. Lastly, between the frame and dial-plate, is the pinion of report, which is that fixed on the arbor of the great wheel, and serves to drive the dial-wheel, as that serves to carry the hand.

Spring or pendulum watches are pretty much upon the same principle with pendulum clocks, whence their denomination. If a pendulum describing little arches of a circle makes vibrations of unequal lengths in equal times, it is evident that it describes the greater with a greater velocity. For the same reason a spring put in motion, and making greater or less vibrations, as it is more or less stiff, and as it has a greater or less degree of elasticity, gives them nearly in equal times. Hence, as the vibrations of the pendulum had been applied to large clocks, to rectify the inequality of their motions, so to correct the unequal motions of the balance of watches, a spring is added, by the isochronism of whose vibrations the correction is to be effected.

The spring is usually wound into a spiral, that in the little compass allotted it, it may be as long as possible, and may have strength enough not to be mattered and dragged about by the inequalities of the balance it is to regulate. The vibrations of the two parts, viz. the spring and balance, should be of some length, only so adjusted as that the spring being more regular in the length of its vibrations than the balance, may on occasion communicate its regularity thereto.

The invention of spring or pocket watches is owing to the artists of the present age. It is true, we find mentions of a kind of a watch called the "Pendulum" by Galen in the history of that prince; but this in all probability was no more than a kind of clock to be set on a table, some resemblance whereof we have still remaining in the ancient pieces made before the year 1070.

In effect, it is between Dr. Hooke and Mr. Huygens, that the glory of this excellent invention bels, to which of them it properly belongs, is greatly disputed; the English ascribing it to Huygens, and that the French, Dutch, &c. to the latter. Mr. Derham, in his Artificial Clock-maker, says plainly that Dr. Hooke was the inventor; and adds, that he contrived various ways of regulation. One way was with a loadstone. Another with a tenderer straight spring, one end whereof played backwards and forwards with the balance, so that the balance was to the spring as the bob to a pendulum, and the spring as the rod of it. This was with the balance, of which there were divers sorts, some having a spiral spring to the balance for a regulator, and others without. But the way that prevailed and continued in mode, was with one balance, and one spring running round the upper parts of the verge; though this has a disadvantage which those of two springs, &c. are free from, in that a sudden jerk or confused shake will alter its vibrations, and put it in an unusual hurry.

We shall conclude this article with an account of the mechanism of a common pocket-watch.

The Plate Watch-work, explains the construction of a common pocket-watch. The moving power is a spiral steel spring (fig. 3), which is coiled up close by a tool used for the purpose, and put into a brass box (fig. 2) called the barrel: the spring has a hook at its outer end which is put through a hole in the side of the barrel and riveted; the inner end has an oblong opening cut through it, to receive a hook upon the barrel arbor (fig. 6); this arbor goes through the bottom of the barrel, and is square to hold a worm-wheel d, (fig. 5) which is turned round by a worm b; the ends of the arbor project below this, and it is pivoted into the lower plate A (fig. 8) of the watch: the top of the barrel has a square hole through which the pivot of the arbor projects, and works in a socket in the upper plate D.

The barrel thus mounted has a steel chain a, (figs. 1 and 8) hooked to its upper end, and that of the barrel, the chain is hooked to the lower part of the fusee E (figs. 1 and 8). It is evident that when the fusee is turned by the watch-key, it will wind the chain of the barrel on itself; and as one of the springs is fastened to the barrel, and the other is hooked to the arbor (which is prevented from turning by the worm-wheel beneath), the spring will be coiled up into a smaller compass than it was before, and by its re-action will, when the watch-key is taken off, turn the fusee and keep the watch going.

The fusee has a spiral groove cut round it, as shewn in fig. 4, in which the chain lies: this groove is cut by an engine, so that the chain shall pull from the smallest part of the fusee, when the spring is wound, and act with its greatest force; and gradually increases in size as the spring unwinds and acts with less power, so that the effect upon the great wheel e (figs. 1, 8, and 7) was always the same, and that when the spring is full, it round in the other direction, it may move the great wheel with it, and the other wheels of the watch.

The great wheel e has 48 teeth on its circumference, which take into a pinion of 12 teeth, fixed on the same arbor with the centre-wheel g, and fig. 9, which has 54 teeth to turn a pinion of six leaves on the arbor of the third wheel h, and fig. 10; the third wheel has 45 teeth, and turns a pinion of six on the arbor of the fusee i, and fig. 11, which has 48 teeth cut parallel to its axis, by which it turns a pinion of six leaves, fixed to the balance-wheel k, fig. 8, 12, and 14. The pinion of the arbor of this wheel turns, one in a frame F, (fig. 8, and fig. 15) called the potance, fixed to the upper plate; and the other in a small piece fixed to the upper part, called the counter-potance, so that when the two plates are put together, the balance-wheel pinion slides on the teeth of the contrate wheel. The balance wheel has 15 teeth, by which it impels the balance l, (figs. 8 and 16, and fig. 13) the arbor of the balance, which is called the verge, has two pallets projecting from it nearly at right angles to each other; these are acted upon by the balance wheel, as shewn in fig. 14, where the lower pallet is supposed to be in contact with one of the teeth of the balance wheel, which, as it turns round, pushes the pallet round and the balance with it, till the balance has made about a quarter of a turn: the tooth of the balance wheel then slips off and escapes; in this position the watch would run down if it were not for the upper pallet at that instant taking another tooth on the opposite side of the balance wheel, which, as it moves in a contrary direction, pushes the balance back again, till the tooth escapes the lower pallet, and then engages the upper pallet, as before. But for the better regulation of the time, the balance has a very fine spring m, (fig. 16), called the pendulum spring, with the inner end fixed to the verge just beneath the outer end, and the outer end pinned to a stud fixed to the top of the upper plate of the watch, so that the balance will rest only in one position, and if it is moved either way by the balance wheel, it will be instantly put to ease by the spring to the spring will have a tendency to turn back. When the lower pallet, for instance, has just liberated a tooth of the balance wheel, the pendulum spring is strained, and returns the balance to its point of rest instantaneously, the balance wheel following the upper pallet by the action of the main spring; and when the balance wheel comes to push the balance beyond its point of rest the other way, it moves slowly, because it has the elasticity of the pendulum spring to overcome.

It is evident that by strengthening or weakening this spring, the velocity of the balance can be regulated, which is done by a contrivance shewn in fig. 16, and shewn the plate of brass screwed to the top of the upper plate, close under the balance; and at one place it is hollowed out to receive a wheel or of 20 teeth, which turns a segment of a wheel p, which moves round in a circular groove: it has a projecting leaf g, with a notch in it to receive the pendulum spring; so that by turning the wheel with a key put on a square part of its arbor, the spring is lengthened or shortened, so as to give it a different power, and make the balance vibrate quicker or slower; the arbor of the wheel n, has a dial r, (fig. 16) upon it, with divisions to set by. The upper pivot of the verge runs in a cock screw to the upper plate, as shewn in fig. 8, which covers the balance and protects it from violence; and the lower pivot works in the bottom of the potance; the socket for the pivot of the balance wheel is made in a small piece, and on a side there is a groove made in the potance, as shewn in fig. 15, so that by drawing the slide in or out, the teeth of the balance wheel shall just clear one pallet before it takes the other.

The verge is thus adjusted by the pendulum spring; that the balance shall vibrate so as to
WAT

WAT

WAT

1. Rain water, unless when near a town, or when collected in a covered place, or in a current of the rain, possesses the properties of good water in perfection, and is as free from foreign ingredients as any native water whatever. The substances which it holds in solution are air, carbonic acid, and lime, and, according to Bergman, it yields some traces of nitric acid, and a little muriate of lime. The quantity of air in good water does not exceed \( \frac{7}{9} \) of the bulk. One hundred cubic inches of water contain generally about one cubic inch of carbonic acid, and hence its presence in the water.
The substances hitherto found in mineral waters amount to about 38, and may be reduced under the four following heads: 1. Air and its constituents, and azotic gases. 2. Acids. 3. Alkalies and earths. 4. Salts.

I. Air is contained in by far the greater number of mineral waters: its proportion does not exceed 1/80th of the bulk of the water.

2. Oxygen gas was first detected in waters by Scheele. Its quantity is usually inconsiderable; and it is incompatible with the presence of sulphated hydrogen gas or iron.

3. Azotic gas was first detected in Poitou water by Dr. Pearson. Afterwards it was discovered in Harrowgate waters by Dr. Garnet, and in those of Lenington Priors by Mr. Lambe.

II. The only acids hitherto found in waters, except in combination with a base, are the four following: carbonic, sulphurous, boracic, and sulphated hydrogen gas. 1. Carbonic acid was first detected in Pyrmont water by Dr. Browning. It is the most common ingredient in mineral waters, 100 cubic inches of the water generally containing from six to 40 cubic inches of this acid gas. According to Westrum, 100 cubic inches of Pyrmont water contain 187 cubic inches of it, or almost double its own bulk. 2. Sulphurous acid has been observed in several of the hot mineral waters in Italy, which are in the neighbourhood of volcanoes. 3. The boracic acid has also been observed in some lakes in Italy. 4. Sulphated hydrogen gas constitutes the most conspicuous ingredient in those waters which are distinguished by the name of hepatic or sulphaurous.

III. The only alkali which has been observed in mineral waters, uncombined, is soda; and the only earthy bodies are silica and lime. 1. Dr. Black detected soda in the hot minerals of Geyser and Rykum in Iceland; but in most other cases the soda is combined with carbonic acid. 2. Silica was first observed in waters by Bergman. It was afterwards detected in those of Geyser and Rykum by Dr. Black, and in those of Carlsbad by Kahlmann. It has been observed in the waters of Pongues, and Breez in those of Pu. It has been found also in many other mineral waters. 3. Lime is said to have been found uncombined in some mineral waters; but it has not been proved in a satisfactory manner.

IV. The only salts hitherto found in mineral waters, are the following sulphates, nitrates, muriates, carbonates, and hydroxylsures:

1. Sulphate of soda
2. Ammonia
3. Lime
4. Magnesia
5. Alumina
6. Iron
7. Copper
8. Nitrate of potash
9. Lime
10. Magnesia
11. Muriate of potash
12. Soda
13. Ammonia
14. Barytes
15. Lime
16. Magnesia
17. Alumina
18. Magnesite

19. Carbonate of potash
20. Ammonia
21. Lime
22. Magnesia
23. Alumina
24. Carbonate of lime
25. Hydrosulphuret of lime
26. Potass
27. And likewise borax.

Of these genera the carbonates and muriates occur by far most commonly, and the nitrates most rarely. 1. Sulphate of soda is not uncommon, especially in those mineral waters which are distinguished by the epithet saline. 2. Sulphate of ammonia is found in mineral waters near volcanoes. 3. Sulphate of lime is exceedingly common in water. Its presence seems to have been first detected by Dr. Lister in 1832. 4. Sulphate of magnesia is almost constantly an ingredient in those mineral waters which have purgative properties. It was detected in Epsom waters in 1610, and in 1690 Dr. Grew published a treatise on it. 5. Alum has sometimes been found in mineral waters, but is exceedingly rare. 6. Sulphate of iron occurs sometimes in Pyrmont mineral waters, and has been observed in other places. But sulphate of copper is only found in the waters which issue from copper mines. 7. Nitrate of lime has been observed in some springs in Hungary; but it is exceedingly uncommon. 8. Nitrate of lime was first detected in water by Dr. Home of Edinburgh, in 1756. It is said to occur in some springs in the sandy deserts of Arabia. 9. Nitrate of magnesia is said to have been found in some springs. 10. Muriate of potash is uncommon; but it has lately been observed in the mineral springs of Ulinsburg in Sweden, by Julius. 11. Muriate of soda is so exceedingly common in mineral waters, that hardly a single spring has been analyzed without detecting some of it. 12. Muriate of ammonia is uncommon; but it has been found in some mineral springs in Italy, and in Siberia. 13. Muriate of barytes is still more uncommon; but its presence in mineral waters has been announced by Bergman. 14. Muriate of lime and magnesia are common ingredients. 15. Muriate of alumina has been observed in water by Mr. Withering, but it is exceedingly rare. 16. Muriate of manganese was mentioned by Bergman as sometimes occurring in mineral waters. It has lately been detected by Lambe in the waters of Lenington Priors, but in an extremely limited proportion. 17. The presence of carbonate of potash in mineral waters has been mentioned by several chemists; if it does occur, it must be in a very small proportion. 18. But carbonate of soda is, perhaps, the most common ingredient of these liquids, if we except common salt and carbonate of lime. 19. Carbonate of ammonia has been discovered in waters; but it is uncommon. 20. Carbonate of lime is found in all mineral waters, and is usually held in solution by an excess of acid. It appears from the different experiments of chemists, as stated by Mr. Kirwan, and especially from those of Berthold, that water saturated with carbonic acid contains 9.002 of carbonate of lime. When the proportion of water is increased, it is capable of holding the carbonate of lime in solution, even when the proportion of carbonic acid united with it is diminished. Thus 24,000 parts of water are capable of holding two parts of carbonate of lime in solution, even when they contain only one part of carbonic acid. The greater the proportion of water, the smaller a proportion of carbonic acid is necessary to keep the lime in solution; and when the water is increased to a certain proportion, no sensible excess of carbonic acid is necessary. It ought to be remarked also, that water, how small a quantity soever of carbonic acid it contains, is capable of holding carbonate of lime in solution, provided the weight of the carbonic acid present exceeds that of the lime. These observations apply equally to the other earthy carbonates, held in solution by mineral waters.

21. Carbonate of magnesia is also very common in mineral waters, and is almost always accompanied by carbonate of lime. 22. Carbonate of alumina is said to have been found in waters; but its presence has not been ascertained. 23. But carbonate of iron is by no means uncommon; indeed it forms the most remarkable ingredient in those waters which are distinguished by the epithet chalybeate. 24. The presence of lime and soda have been frequently detected in those waters which are called sulphurous or hepatic. 25. Borax exists in some lakes in Persia and Thibet; but the nature of these waters has not been ascertained.

Besides these substances, certain vegetable and animal matters have been occasionally observed in mineral waters. But in most cases they are rather to be considered in the light of accidental mixtures than of real component parts of the waters in which they occur.

From the above enumeration, we are enabled to form a pretty accurate idea of the nature of mineral waters which occur in this kingdom; but this is by no means sufficient to make us acquainted with these liquids. No mineral water contains all of these substances. Several are there more than five or six of them present together, and rarely exceed the number of eight or ten. The proportion too in which they enter into mineral waters is generally small, and in many cases extremely so. Now in order to understand the nature of mineral waters, it is necessary to know the substances which most usually associate together, and the proportion in which they commonly associate. In the greater part of mineral waters there is usually some substance present which, from its greater proportion or its greater activity, stamps, in a manner, the character of the water, and gives it those properties by which it is most readily distinguished. This substance of course claims the greatest attention; while the other bodies which enter in a smaller proportion may vary or even be absent altogether, without producing any sensible change in the nature of the water. This circumstance enables us to divide mineral waters into classes, distinguished by the pre-
cular substance which predominates in each. Accordingly they have been divided into four classes, namely:

1. Acidulous.
2. Chalybeate.
3. Hepatic.
4. Saline.

1. The acidulous waters contain a considerable proportion of carbonic acid. They are easily distinguished by their acid taste, and by the sparkling like champagne wine when poured into a glass. They contain almost constantly some common salt, and in general also a greater or smaller proportion of the earthy carbonates.

2. The chalybeate waters contain a portion of iron, and are easily distinguished by the property which they have of striking a black with the tincture of nattails even after being boiled and filtered; whereas boiling decomposes the carbonate of iron, and causes its base to precipitate.

3. The hepatic or sulphureous waters are those which contain sulphurated hydrogen gas. These waters are easily distinguished by the colour of the aseinated hydrogen gas which they exhale, and by the property which they have of blackening silver and lead. The nature of the waters belonging to this class long puzzled chemists. Though they often deposit sulphur spontaneously, yet no sulphur could be artificially separated from them. The secret was at last discovered by Bergman. These waters are of two kinds: in the first the sulphurated hydrogen is uncombined; in the second it is united to lime or an alkali. They are frequently also impregnated with carbonate of iron, and usually contain some muriates or sulphats.

4. Saline waters are those which contain only salts in solution, without iron or carbonate of iron in excess. They may be distinguished into four different orders. The waters belonging to the first order contain salts whose base is lime, and generally either the carbonate or the sulphat. They are known by the name of hard waters, and have but a slight disagreeable taste. The waters belonging to the second order are those in which common salt predominates. They are readily recognized by their salt taste, and like sea water usually contain some magnesium and sulphate of soda. The waters of the third order contain sulphat of magnesia. They have a bitter taste and are purgative.

Finally, the waters of the fourth order are alkaline containing carbonate of soda. They are easily distinguished by the property which they have of tinging vegetable juices green.

The following table exhibits a synoptical view of the component parts of a considerable number of mineral waters as analysed by different chemists. See Dr. Saunders's Treatise on the Chemical History and Medical Powers of the most celebrated Mineral Waters.

One pint of the Bath water contains (according to the laborious and delicate analysis of Mr. Phillips),

- Carbonic acid
- Muriat of soda
- Sulphat of soda
- Sulphat of lime
- Carbonat of lime
- Silica
- Oxide of iron

Waters, the method of analysing. The analysis of waters, or the art of ascertaining the different substances which they hold in solution, and of determining the proportion of these substances, is one of the most difficult branches of chemistry. The difficulty arises, not only from the diversity of the bodies which occur in waters, but from the very minute quantities of some of the ingredients.

Though many attempts have been made to analyse particular waters, and several of these were remarkably well conducted, no general mode of analysis was known till Bergman published his Treatise on Mineral Waters in 1778. This admirable treatise carried the subject all at once to a very high degree of perfection. The Bergmannian method has been followed by succeeding chemists, to whom we are indebted not only for a great number of very accurate analyses of mineral waters, but likewise for several improvements in the mode of conducting the analysis.

Mr. Kirwan has in 1799 published an essay on the general analysis of waters, no less valuable than that of Bergman; containing all that has hitherto been done on the subject, and enriched by the numerous experiments of Mr. Kirwan himself, which are equally important and well conducted. Mr. Kirwan has given a new method of analysis, which will probably be adopted hereafter; not only because it is shorter and easier than the Bergmannian, but because it is susceptible of a greater degree of accuracy.

The method of analysing consists in two different branches: 1. The method of ascertaining the different substances contained in the water which we are examining. 2. The method of determining the exact proportion of each of these ingredients.

The different bodies which are dissolved and combined in water, are discovered by the addition of certain substances to the water, which is subjected to examination. The consequence of the addition is some change in the appearance of the water; and this change indicates the presence or the absence of the bodies suspected. The substances thus employed are distinguished by the name of tests, and are the instruments by means of which the analysis of water is accomplished. They were first introduced into chemistry by Boyle, and were gradually increased by succeeding chemists; but Bergman was the first who ascertained with precision the degree of confidence which can be placed in the different tests. They still continued rather uncertain and precarious, till Mr. Kirwan showed how they might be combined and arranged in such a manner as to give certain and precise indications whether or not any particular substance constitutes a component part of the water. Let us consider by what means the preceifce or the absence of all the different substances which occur in waters may be ascertained.

1. The gaseous bodies contained in water are obtained by boiling it, and by retort luted to
a pneumatic apparatus. The method of separating alkalis containing these different bodies shall be described hereafter.

II. The presence of carbonic acid, not combined with a base, or combined in excess, may be detected by the following tests: 1. Lime-water occasions a precipitate soluble with effervescence in muriatic acid. 2. The infusion of litmus is reddened; but the red colour gradually disappears, and may be again restored by the addition of more of the mineral water. When boiled it loses the property of reddening the infusion of litmus.

III. The mineral acids when present, uncombined in water, give the infusion of litmus a permanent red, even though the water has been boiled. Bergman has shown that paper, stained with litmus, is reddened when dipped into water containing 1-321 of sulphuric acid.

IV. Water containing sulphuretted hydrogen gas is distinguished by the following properties: 1. A peculiar odour of sulphuretted hydrogen gas. 2. It reddens the infusion of litmus fugaciously. 3. It blackens paper dip into a solution of lead, and precipitates the nitrate of silver black or lead. V. Alkali and earthy carbones are distinguished by the following tests: 1. The infusion of turmeric, or paper stained with turmeric, is rendered brown by alkali, or reddish-brown if the quantity is minute. This change is produced when the soda in water amounts only to 1-29177th part. 2. Paper stained with Brazil wood, or the infusion of Brazil wood, is rendered blue; but this change is produced also by the alkaline and earthy carbones. It can be ascertained that water containing 1-9945th part of carbonat of soda renders paper stained with Brazil wood blue. 3. Litmus paper reddened by vinegar is restored to its original blue colour. This change is produced by the alkaline and earthy carbones also. 4. When these changes are fugacious, we may conclude that the alkali is ammonium.

VI. Fixed alkalis exist in water which occasions a precipitate with water, which after being evaporated is formed. Volatile alkali may be distinguished by the smell, or it may be obtained in the receiver by distilling a portion of the water gently, and then it may be distinguished by the above tests.

VII. Earthy and metallic carbones are precipitated by boiling the water containing them; except carbont of magnesia, which is only precipitated imperfectly.

VIII. Iron is detected by the following tests: 1. The addition of tincture of nuts galls gives water containing iron a purple or black colour. This test indicates the presence of a very minute portion of iron. If the tincture has no effect upon the water after boiling, though it colours before, the iron is in the state of a carbonat. The following observations of Weatrun on the colours which iron gives to nuts galls, as modified by other bodies, deserve attention:—A violet indicates an alkaline carbonat or earthy salt. Dark purple indicates other alkaline salts. Purplish red indicates sulphuretted hydrogen gas. Whithis and then black indicates sulphat of lime.

IX. The prussian alkali occasion a blue precipitate in water containing iron. If an alkalii is present, the blue precipitate does not appear unless the alkali is saturated with an acid.

X. Sulphuric acid exists in waters which form a precipitate with the following saline solutions: 1. Muriat, nitrat, or acetat of barytes 2. - - - - - - strontian 3. - - - - - - line 4. Nitrat or acetat of lead.

If of these the most powerful is far is muriatic of barytes, which is capable of detecting the presence of sulphuric acid uncombined, when it does not exceed the millionth part of the water. Acetat of lead is next in point of power. The muriatic is more powerful than the nitrat. The calcareous salts are least powerful. All these tests are capable of indicating a much smaller proportion of uncombined sulphuric acid than when it is combined with a base. To render muriat of barytes a certain test of sulphuric acid, the following precautions must be observed: 1. The muriat must be diluted. 2. The alkali, or carbonate of alkali, if the water contains any, must be previously saturated with muriatic acid. The precipitate must be insoluble in muriatic acid. 4. If boracic acid is suspended, muriat of strontian must be tried, which is not precipitated by boracic acid. 5. The hydrosulphurates precipitate barytic solutions, but their presence is easily discovered by the smell.

XI. Muriatic acid is detected by nitrat of silver, which occasions a white precipitate, or a cloud in water containing a minute portion of this acid. To render this test certain, the following precautions are necessary: 1. The alkali or carbonat must be previously saturated with nitric acid. 2. Sulphuric acid, if any should be present, must be previously removed by means of nitrat of barytes. 3. The precipitate must be insoluble in nitric acid.

XII. Boracic acid is detected by means of acetat of lead, with which it forms a precipitate insoluble in nitric acid. To render this test certain, the alkalies and earths must be previously saturated with acetic acid, and the sulphuric and muriatic acids removed by means of acetat of strontian and acetat of silver.

XIII. Barytes is detected by the insoluble white precipitate which it forms with dilute sulphuric acid.

XIV. Lime is detected by means of oxalic acid, which occasions a white precipitate in water containing a very minute proportion of this earth. To render this test decisive, the following precautions are necessary: 1. The mineral acids, if any should be present, must be previously separated with an alkali. 2. Barytes, if any should be present, must be previously removed by means of sulphuric acid. 3. Oxalic acid precipitates magnesia but very slowly, whereas it precipitates lime instantly.

XV. Magnesia and alumina. The presence of these earths is ascertained by the following tests: 1. Pure ammonia precipitates them both, and no other earth, provided the carbonic acid has been previously separated by a mineral alkali and boiling. 2. Lime-water precipitates only these two earths, provided the carbonic acid is previously removed, and the sulphuric acid also, by means of nitrat of barytes.
WATERS.

Besides the substances above described, there is sometimes found in water a quantity of bitumen combined with alkalii, and in the state of soap. In some instances this occurs as a coagulation; and the coagulum collected on a filter discovers its bituminous nature by its combustibility.

Water also sometimes contains extractive matter; the presence of which may be detected by means of nitrat of silver. The water suspected to contain it must be freed from sulphatic and niterous acid by means of nitrat of lead. After this, it is given a brown precipitate with nitrat of silver, we may conclude that extractive matter is present.

The proportion of saline ingredients, held in solution by any water, may be in some measure determined from its specific gravity. The lighter a water is, the more saline it contains; and, on the other hand, the heavier it is, the greater is the proportion of saline contents. 

Mr. Kirwan has pointed out a very ingenious method of estimating the saline contents of a mineral water whose specific gravity is known; so that the error does not exceed one or two parts in the hundred. The method is this: Subtract the specific gravity of pure water from the specific gravity of the mineral water examined (both expressed in whole numbers), and multiply the remainder by 1.4. The product is the saline contents, in a quantity of the water denoted by the number employed to indicate the specific gravity of distilled water. Thus let the water be of the specific gravity 1.072, or in whole numbers 1075, then the specific gravity of distilled water will be 1.000. And 1075 — 1000 = 14 = 0.014 = saline contents in 1000 parts of the water in question; or 1075.0014 = 14.00 = 100 parts of the same water. The formula will often be of considerable use, as it serves as a kind of standard to which we may con
Waters.

The saline contents indicated by it are supposed to be freed from their water of crystallization; in which state only they ought to be used. The tests, in the last section, determined the particular substances which exist in it, let us now proceed to ascertain the proportion of each of these ingredients.

I. The different aerial fluids ought to be first separated and estimated. For this purpose a retort ought to be filled two-thirds with the water, and connected with a jar full of mercury, standing over a mercurial trough. Let the water be made to boil for a quarter of an hour. The aerial fluids will pass over into the jar. When the apparatus is cool, the quantity of air expelled from the water may be determined either by bringing the mercury within and without the jar to a level; or it that cannot be done, by reducing the air to the proportion of eight. The air of the gas is ought to be carefully subtracted, and the jar must be divided into cubic inches and tenths.

The only gaseous bodies in water are common air, oxygen gas, carbonic acid, sulphurated hydrogen gas, and sulphurous acid. The last two never exist in water together. The presence of either of them must be ascertained previously by the application of the proper tests. If sulphurated hydrogen gas be present, it will be mixed with the air contained in the glass jar, and must be separated before air is examined. For this purpose, the jar must be carried into a tube of warm water, and nitric acid introduced, which will absorb the sulphurated hydrogen.

The residuum is then to be again put into a mercurial jar and examined.

If the water contains sulphurous acid, this previous step is not necessary. Introduce the air again into a redness vessel, and the reddish precipitate appears. The iron and part of the magnesia are thus separated. Dry the precipitate, and expose it to the air for some time in a heat of 200°; then treat it with acetic acid, which solution is to be added to the muriatic solution. The iron is to be redissolved in muriatic acid, precipitated by an alkaline carbonate, dried, and weighed.

Add sulphuric acid to the muriatic solution as long as any precipitate appears; then heat the solution and concentrate. Heat the sulphat of lime thus obtained to redness, and weigh it. One hundred grains of it are equivalent to 70 of carbonate of lime. Precipitate the magnesia in the same manner. Dry it and weigh it. But as part remains in solution, evaporate to dryness, and wash the residue with a sufficient quantity of distilled water to dissolve the mirror of soda and the sulphat of lime, if any should be present. What remains behind is carbonate of magnesia. Weigh it, and add its weight to the former. The sulphat of lime, if any, must also be separated and weighed.

III. Let us now consider the method of ascertaining the proportion of mineral acids or alkalies, if any should be present uncombined. The acids which may be present, omitting the gaseous, are the sulphuric, muriatic, and nitric.

1. The proportion of sulphuric acid is easily determined. Satiate it with barites and water; and ignite the precipitate. One hundred grains of sulphat of barytes thus formed indicate 23.5 of real sulphuric acid.

2. Saturate the muriatic acid with barytes-water, and then precipitate the barytes by sulphuric acid. One hundred parts of the ignited precipitate are equivalent to 21 grains of real muriatic acid.

3. Precipitate the boreatic acid by means of acatot of lead. Decompose the borate of lead by boiling it in sulphuric acid. Evaporate to dryness. Dissolve the boratic acid in alcohol, and evaporate the solution; the acid left behind may be weighed.

4. To estimate the proportion of alkaline carbonat present in a water containing it, saturate it with sulphuric acid, and note the weight of real acid necessary. Now 100 grains of real sulphuric acid saturate 121.44 potash, and 78.32 soda.

IV. Let us now consider the method of ascertaining the proportion of the different sulphats. These are six in number, viz., the sulphat of barium and those of lime, alumina, magnesia, and iron.

1. The alkaline sulphats may be estimated by precipitating their acid by means of nitrat of barytes, having previously freed the water of all other sulphats. For 170 grains of ignited sulphat of barytes indicate 100 grains of dried sulphat of soda; while 136.56 grains of sulphat of barytes indicate 100 of dry sulphat of potash.

2. Sulphat of lime is easily estimated by evaporating the liquid containing it to a few ounces (having previously saturated the earthy carbonat with nitric acid), and precipitating the sulphat of lime by means of weak alcaline. It may be then dried and weighed.

3. The quantity of alum may be estimated by precipitating the alumina by carbonat of lime or of magnesia (if no lime is present in the liquid). Twelve grains of alumina (by the heated incandescent indicate one hundred of the crystalized alum, or forty nine of the dried salt).

4. Sulphat of magnesia may be estimated, provided no other sulphat is present, by precipitating the acid by means of a barytate salt; as 100 parts of ignited sulphat of barytes indicate 52.11 of sulphat of magnesia. If sulphat of lime and no other sulphat is present, the last may be decomposed, and the lime precipitated by carbonat of magnesia. The weight of the lime thus obtained enables us to ascertain the quantity of sulphat of lime contained in the water.

5. Sulphat of soda is then to be precipitated by barytes. This gives the quantity of sulphuric acid; and subtracting the portion which belongs to the sulphat of lime, there remains that which was combined with the magnesia, from which the sulphat of magnesia may be easily estimated.

If sulphat of soda is present, no earthy nitrat or muriat can exist. Therefore, if no other earthy sulphat is present, the magnesia may be precipitated; for sulphat of lime, dried, and weighed; 30.68 grains of which indicate 100 grains of dried sulphat of magnesia. The same process succeeds when sulphat of lime accompanies these two sulphats; only in that
case the precipitate, which consists both of lime and magnesia, is to be dissolved in sulphuric acid, evaporated to dryness, and to be treated with twice its weight of cold water; which dissolves the sulphate of magnesia, and leaves the other salt. Let the sulphat of magnesia be evaporated to dryness, exposed to a heat of 400° and weighed. The same process succeeds if shum is present instead of sulphat of lime.

5. Sulphat of iron may be estimated by precipitating the iron by means of prussic alkali, having previously determined the weight of the precipitate produced by the prussat in a solution of a given weight of sulphat of iron in water. If sulphat of iron is also present, which is a very rare case, it may be separated by evaporating the water to dryness, treating the residuum with alcohol, which dissolves the murat, and leaves the sulphat. Or the sulphat may be estimated with great precision by the rules laid down by Mr. Kirwan.

VI. It now only remains to explain the method of ascertaining the proportion of the nitrats which may exist in waters.

1. When nitre accompanies sulphats and murats without any other nitrat, the sulphats are to be decomposed by acetat of barytes, and the residuum, with the nitre, is to be separated by washing, and then dissolved by a slight quantity of hydrochloric acid. The clear liquid, after evaporation, is to be treated with twice its weight of cold water, which dissolves the nitre, and leaves the nitre; the quantity of which may be easily estimated. If an alkali is present, it ought to be previously saturated with sulphat of lime or magnesia.

2. If nitre, common salt, nitrat of lime, and nitrat of magnesia are present together, the water ought to be evaporated to dryness, and the dry mass treated with alkaline, which takes up the earthy salts. From the residuum, resolved in water, the nitre may be separated, as estimated as in the last case. The alcohol solution is to be evaporated to dryness, and the residuum resolved into water.

Let us suppose it to contain nitrat of magnesia and nitrat of lime. Precipitate the muriatic acid by nitrat of silver, which gives the proportion of muriat of magnesia and of lime. Separate the muriat of magnesia by means of carbonate of lime, and note its quantity. Then subtract the quantity of muriat of magnesia. And subtracting the muriatic acid contained in that salt from the whole acid indicated by the precipitate of silver, we have the proportion of muriat of lime.

Lastly, subtract the acid which has been added to precipitate the muriat with nitric acid. Then precipitate the whole of the lime by sulphuric acid; and subtracting from the whole of the sulphat thus formed that portion formed by the carbont of lime added, and by the lime contained in the muriat, the residuum gives us the lime contained in the original nitrat; and 35 grains of lime form 100 of dry nitrat of lime.

WATER-SEA. See Sea.

WATER-COLOURS. Painting in water-colours, is an art capable of affording the highest delight to the eye, since no mode of representation can display the appearances of nature with greater splendour. It is an art which has been brought forward with unprecedented success, and may be at present to be the most perfect species of design or painting, which is in practice amongst our artists. To this the facility of the materials employed in it contributes in no small degree. It is not attended with the embarrassments to which oil-painting, or most other kinds of painting, are liable, but proceeds by ready and uninterrupted progress to the completion of its task.

The preliminary parts of study requisite for the true student in the attainment of this art, have been treated under the article of Drawing. See Drawing. We can recommend no more advantageous method for his further progress, than the careful studying and copying the various works of excellence by the best masters, until he shall be able to follow, if not to rival them, in the imitation of nature. We shall now endeavour to furnish him with the best means for this purpose, by describing the colours which are employed in washing, and giving the most approved directions for preparing and using them.

The materials and implements necessary for the practice of water-colours (or washing, as it is sometimes called) are,—gum-colours, of which we shall treat more particularly; camels' hair pencils, fitches, a palette, and penknife.

The general or simple colours, and the various species of each, fit for painting in water-colours, are as follow:

WATER COLOURS.

Blacks.  Reds.
Burnt cherry-stones  Indian red
very-black  Burnt ochre
King's black  Indian red
Lamp-black  Lead lead
Green bice  Minimum
Green verditer  Vermilion
Sap-green  Carmine
Crushed rose distilled  Indian lake
Blues.

Yellow.

Snakers blue  English ochre
Terra-calle  Gaul-stone
Blue verditer  Gamboge
Lime green  Lead white
Lithium  Ochre de luce
Smalt  Orpiment
Prussian blue  Roman ochre
Light ditto  Dutch pink
Ultramarine  Saffron-water
Ultramarine ashes  King's yellow
Blue bice  Gold yellow
French beries.

Directions for preparing the following single colours.

Whites.
The best white for painting in water-colours is white lead; some mix a white made of pearl and oyster-shells, brought to an impalpable powder, called a pearl-white, which will mix well with any colour. If you use white lead, clarify it with white-wine, the white is settled, pour off the vinegar, and wash it with water thus: Put the powder into a glass of water, stir it, and presently pour the water off, while it is white, into another clean glass; when it is settled, pour off the water, and you will have an excellent white; to which add as much gum as is necessary, to give it a gloss.

It has been often noticed, that white lead will turn black, if mixed with water that comes from iron or clay; so that, in the space of a month or two, you may perceive it: and it will also change any colour with which it is mixed.

Some therefore recommend the powder of egg-shells, of the brightest and whitest sort, well ground with gum-water, to the state of an impalpable powder, to which they add one-twentieth, or part of white lead; others esteem it most when clarified in spirit of wine, and then use it with gum-water.

It has been found, by repeated experiments, that this egg-shell powder is extremely serviceable as a white, in water-colours; and that this, and the oyster-shell powder, rectified and well bruised, will make an excellent mixture with other colours, to keep them from changing.

A fine white, for water-colours, may be made by dissolving filings of silver, or silver-leaf, in aqua-fortis, evaporating the aqua-fortis till it appears like crystal in the bottom of the glass; decant the other part of the aqua-fortis, and wash the silver four or five times in pure water, till it is entirely cleaned from the aqua-fortis, drying it for use. It must be used with the waters of gum and sugar-candy.

A good white for water-colours, proper for miniature, is made thus: Take a pound of the shreds of glove-leather, and steep them in water; boil them with twelve quarts of water, till it wastes to two; strain it through a linen cloth, into a well-glazed earthen pan; this is called glue or size, and proper to use with colours in candle-light pieces; to know if this is strong enough, try if it is stiff, and firm under your hand.

The glue being melted, reduce some white chalk to a powder, while it is hot, add such a quantity of the chalk as will bring it to the consistency of a paste, letting it steep for a quarter of an hour; stir it with a brush made of hog's bristles.

In order to make this white brighter, add more glue. Be careful to observe that every layer is dry, before you put on another. If you work upon wood, you must put on a dozen; but six or seven are sufficient if your paper is thick. Afterwards dip a soft brush in some water, draining it with your fingers; rub the work with it, in order to make it the smoother. When your brush is full of white, you must wash it again; and also change the water when it is too white. Or you may use a wet linen rag, instead of a brush.

Yellows.

In some objects there may be seen a shining, like that of gold, through colours of red, blue, or green, such as some sort of plant that the cantharides. This gold or transparency may be well imitated by laying some leaf-gold on the shaded side of the drawing, giving a little to the light side. To lay on the gold-leaf, press it smooth; or, if you have washed it with strong gum-water; but care must be taken, that in laying on the gum, you do not exceed the limits through which you would have the gold appear. In this case, the gold is only to shine through the transparent colour, which is to be laid over it.

As leaf-gold will not receive water-colours regularly, it is necessary to be provided with water of ox-gall, and with this liquor to stroke over the gold-leaf; by which it will receive any colour you are desirous of laying over it, and will also retain it.

In some manuscripts there may be seen gold letters, which seem to rise above the surface of the paper. The composition which raises them, is made of vermilion and the white of an egg, beaten to the consistence of an oil, and fixed to the paper with gum-ara-bic; on this figurative letter, wash some gum-water, then lay on the gold-leaf closely with a camel's-hair pencil; lay on the gold-leaf close with some cotton; and when dry, rub it again with cotton, and polish it with a dog's tooth, and it will appear as if it was cast in gold.

There is also another way of working in gold, which is performed by shell-gold (but then it must be pure, and not that brought from Germany, which turns green in a few days).

Cover the shady parts with vermilion, before you use the gold; and when you have rectified it with spirit of wine, lay it on; when dry, burnish it as before directed.

In laying on this gold, it is best to leave the lights without it, as it will appear to a much greater advantage than if all the objects were covered; but, provided the whole performance should chance to be covered, the best way of setting it off, is to trace over the shady parts with gall-stone, or the yellow made of French berries, (of which we shall treat hereafter), heightened with minimum.

Of yellows in general. Gamboge is, beyond doubt, one of the meellowest colours nature has produced; it is of so mild a temperament, that when it is touched with any fluid, it instantly dissolves; so that, consequently, it wants neither gumming nor grinding; it is productive of a variety of the most agreeable and pleasant yellow tints, that fancy or art could ever imagine; in it is to be found that shade itself, though sometimes it requires help.

Gall-stone is a very rich deep yellow, tending towards a brown; it is exceedingly useful in many cases, needs but little gumming or grinding, works freely, but will not show itself.

Mr. Boyle says, if you cut the roots of berberies, and put them into a strong liquid, made of pearlashes and water, from them will proceed a very agreeable yellow. This experiment has often been made, and as often attended with success.

He also gives an account of another fine transparent yellow, by boiling the root of a mulberry-tree, well cleansed, in the foregoing liquid.

Yellow ochre makes a very good pale yellow, and, being ground with gum-water, will prove extremely useful.

Another very useful yellow, is made by dissolving the resin of the tree that yields the black gum-water, gently pressing it, adding to the liquor some alum-water, letting it boil.

The virtue of the yellow extracted from French berries is so well known, that we need only give the directions for preparing it. In a quart of the preceding liquid, boil two ounces of French berries, till the liquor is of a fine yellow; strain it from the yellow berries, and when cold it is fit for use. To the berries put a pint of the same liquid, and boil it till the liquor is as strong as gall-stones; with which you may shade any yellows; this you may boil till it comes to a brown, and will, with the addition of a little ox-gall, serve to shade the gold-leaf.

You may likewise make a yellow, by infusing saffron in pure water. When this is steeped in rectified spirit of wine, there is nothing higher; but it is very apt to fly, unless it is high-gummed.

A good yellow, for the illumination of prints, may be extracted from the roots of ginger; which make a good green, when mixed with transparent verdigrise.

Those yellows called English and Dutch greens, are made with French berries, ground to a fine powder, and then boiled.

King's yellow, a fine body-colour, is much used in heightening the ochre for gold lace, &c.

Orange colour. This colour is made of a mixture of vermilion and gamboge, the latter most predominant, in which you have a servicable colour in painting flies, and all other orange-coloured flowers. Orpiment is likewise a pleasing colour.

Reds.

Red-lead, or minium, is a strong heavy colour. Mr. Boyle has given us the following directions for preparing it: Put four ounces in a glass, to a quart of rain-water, and when it has been thoroughly stirred, pour off the water: and by a frequent repetition of this, there will remain at the bottom of the glass a beautiful red, when dry, which is to be used with gum-water. When the colour has been thus prepared, you must not expect above twenty grains to remain out of four ounces.

Carmine affords the brightest and most perfect crimson, and is the most beautiful of
all reds: for with this colour and lake you may make the shades as strong as you please. This colour should never be purchased but by day-light; for if not good, it will but spoil your work.

Lake is a fine transparent colour, not much inferior to Carmine; but in painting with Carmine on that part of the print on which the light is supposed to strike, lay on the first tint as light as possible, working it stronger as it grows darker, and touch it in the darker parts with lake.

Lake may be bought at most colour-shops, ready prepared for water-colours; but if you are desirous of making it yourself, it is necessary to adhere to the following directions: Having prepared a Liquidum, made with the ashes of vine-barks, to three pints of it add a pound of the best ground brazal wood; boil it till half the Liquidum is evaporated; strain off; boil it again with the addition of four ounces of fresh brazal wood, two equal quarts of cochineal, half a minute of terramarita, and a pint of fair water; let it evaporate as before; add half an ounce of burnt alum (reduced to an impalpable powder), a quarter of a drachm of arsenic; dissolve the arsenic in it, by stirring it with a stick; when settled, strain it. To give this a body, reduce two cuttlefish bones to a powder, and putting it in, let it dry leisurely. Grind it in a quantity of fair water, in which you may let it steep; strain it through a cloth, and making it into a few cakes, set it by for use, after drying it on a piece of marble.

If you would have this lake redder, add some of the juice of a lemon; and to make it deeper, add a little oil of tartar.

Another lake: Boil the shreds of superfine scarlet cloth in a lye made of the ashes of burnt tartar; when sufficiently boiled, add some cochineal, powdered mastich, and cochine alum; boil this again; while it is quite hot, strain it through a bag several times.

The first time, the bag must be strained from top to bottom, and the remaining gross matter being taken out, let the bag be well washed; after this, strain the liquor through the bag again, and you will find a paste remaining on the sides, which divide into small cakes, and set by for use.

Another lake: Steep four ounces of the best brazal wood in a pint and a half of the finest distilled vinegar, for three weeks at least, though the longer it remains the better it is; seethe the whole in balsam maria, till it boils up three or four times; let it settle for a day or two; put it to an ounce of powdered alum, and into a clean pan with the liquor; let it remain for twenty-four hours; heat the composition, and stir it till it is cold; when it has stood about twelve hours, strain it, and add two cuttlefish bones, prepared as before.

A liquid colour of a very good crimson, is made as follows: In twelve ounces of pale stale beer, boil one ounce of ground brazal wood, till the colour is as strong as you desire; strain it through a lines cloth, and bottle it up for use. If you want to bring this colour to body, take some dry ox-blood, reduced to a powder, and mix it with the colour.

We have the following directions from Mr. Beale, for extracting a fine crimson from the berry-bearing spinach, which, being pressed, afford a very agreeable juice; to which add a fourth part of alum; boil it, and when cold it is fit for use.

Or you may extract a very beautiful red from the red beet-root, baked with a little strong vinegar and alum: when cold it is fit for use.

Another way to make a crimson: Put twenty or more grains of bruised cochinel into a gallon, with as many drops of the lye of tartar as will make it a good oil colour; add to this mixture about half a spoonful of water, or more, and you will have a very agreeable purple; reducing some alum to a very fine powder, put it to the purple liquor, and you will have a beautiful crimson; strain it through a fine cloth; use it as soon as possible; for though this is a colour which, if soon used, looks extremely well, yet by long standing it is subject to decay.

Indian lake is far superior to any other of the kind, for the deep shade of reds of all kinds, and works as free as gamboge. The best is brought from China, in pots, and has the appearance of raspberry-jam, but very bitter to taste: it requires no gum.

Purple: Take eight ounces of logwood, a pint of rain water, and an ounce of alum; ilter it well over a slow fire, in a well glazed pan or pipkin, for about twenty-four hours; and when clear, let it stand for a week: strain it through a piece of fine cloth. Keep it close, or it will mould.

Or you may make a redder purple, by adding to one ounce, four ounces of brazal wood, and a pint of stale beer, boiling it till the liquor is as strong as you desire. It may be made darker, by adding more logwood.

The richest purple is made by blending Carmine and Prussian blue, or indigo, to what shade you please.

Blues. Ultramarine is the best and brightest blue. Prepare it by heating six ounces of the lapis lazuli till it is red; cool it in strong vinegar; grind it with a stone and muller to an impalpable powder; then make a composition of bees-wax, resin, linseed oil, and turpentine, of each three ounces; in a pot put together over a slow fire, till it is near boiling; pour them into a pan well glazed. This is called the paste of ultramarine. The lapis lazuli being prepared, add to it an equal quantity of the paste, or paste, mix them together thoroughly, and let them remain twelve hours. To extirpate the ultramarine from the paste, pours clear-water upon it; on pressing the paste with your hands, the ultramarine will come out for its reception, place a glass tumulder under your hands; let it settle in this water till the ultramarine sinks to the bottom.

If the colour seems foul, cleanse it thus: Dissolve some tartar in water; add as much of it to the ultramarine as will cover it; let it stand twelve hours; wash it in warm water, and you will have your colour well charmed and perfectly clear. Let your ultramarine be of a high colour, and well ground.

Next to ultramarine in beauty, is Prussian blue; but it does not grind kindly with water, on account of its oily substance.

Blue bico is a colour of a very good body, and flows very agreeably in the pencil; wash it according to the rules laid down for ultramarine.
WATER-COLOURS.

Directions for preparing the following mixed colours.

Ash colour. Ceruse, Knapping's black, and white, shaded with cherry-stone black.

Bay. Lake and lake white, shaded with carmine; bistre and vermilion, shaded with black.

Changeable silk. Red and mastic-water, shaded with sap-green and verdigrise.

Another. Lake and yellow, shaded with lake and Prussian blue.

Cloud colour. Mastic, lake and white, shaded with blue verdigrise.

Another. Constant white and Indian ink, a little vermilion.

Another. White, with a little lake and blue verdigrise, makes a very agreeable cloud-colour, for that part next the horizon.

Crimson. Lake and white, with a little vermilion, shaded with lake and carmine.

Flame colour. Vermilion and opimient, heightened with white.

Another. Gamboge, shaded with minimum and red-smalt.

 Flesh colour. Ceruse, red lead, and lake, for a swarthy complexion, and yellow-oche.

Another. Constant white and a little carmine, shaded with Spanish liquorice, washed with carmine.

French green. Light pink and Dutch bice, shaded with green pink.

Glassy green. Ceruse, with a little blue of any kind.

Hair colour. Mastic, oche, umber, ceruse, and cherry-stone black.

Lead colour. Indigo and white.

Light blue. Blue bice, heightened with lake white.

Another. Blue verdigrise, and white of any sort, well ground.

Light green. Pink, mixed, and white.

Another. Blue verdigrise and gamboge.

Another. Gamboge and verdigrise. The chief use of this green is to lay the ground-colours for trees, fields, &c.

Lion aching. Red lead, and mastieot, shaded with umber.

McCoy. Lake and white lead.

Orange. Red lead and a little mastic, shaded with bull-stone and lake.

Orange toady. Lake, light pink, a little mastic, shaded with bull-stone and lake.

Pearl colour. Carmine, a little white, shaded with lake.

Popinjay green. Green and mastic, and pink and a little indigo, shaded with indigo.

Purple. Indigo, Spanish brown, and white; or blue lake, red and white lead; or blue bice and lake.

Raset. Cherry-stone black and white.

Scarlet. Red lead and lake, with or without vermilion.

Sax green. Bice, pink, and white, shaded with pink.

Ske colour. Light mastic and white, for the lowest and lightest parts; second, red ink and white; third, blue-bice and white; fourth, blue lake alone. These are all to be softened into one another at the edges, so as not to appear harsh.

Sky colour for drapery. Blue bice and carmine, or ultramarine and white, shaded with indigo.

Snow colour. Mastic and a very little lake, shaded with Dutch pink.

Violet colour. Indigo, white, and lake; or the Dutch bice and lake, shaded with indigo; or litmus, small, and bice, the latter most predominant.

Water. Blue and white, shaded with blue, and heightened with white.

Another. Blue verdigrise, shaded with indigo, and heightened with white.

Directions for using the colours.

Your pencils must be fast in the quills, and sharp-pointed (after you have drawn them through your mouth), not apt to part in the mixing.

Before you begin, have all your colours ready, and a palette for the convenience of mixing them; a paper to lay under your hand, as well as to try your colours upon; also a large brush, called a fitch, to wipe off the dust from them.

Being prepared according to the foregoing method, proceed in your painting; which if a landscape, lay on first dark colours freely all over your piece, leaving no part uncovered.

Having laid your dark colours, begin next with the lighter parts, as the sky, sea, ground-grounds, &c.; then the yellowish beams, with mastic and white; next the blueness of the sky, with blue verdigrise alone; for purple clouds, white, with the best indigo; for the sea, with your colours deeper as they go upwards from the horizon, except in tempestuous skies. The tops of distant mountains must be worked so faint, that they may seem to lose themselves in the air.

Bring your colours forward as your distance decreases; painting your first ground next the horizon, downwards, of a bluish sea-green; and as you advance forward, of a darker green, till you come to the fore-ground itself; which, as it is the darkest part of all, with dark green, worked in such a manner as to give the appearance of shrubbery, &c.

In painting trees, having first loaded a verdigrise green for a dead color, proceed with working it so as to give a leafy appearance. Bring some of your leaves forward with mastic and white, for the trunk, work the brown with sap-green; if you should introduce them, lay on some touches to express leaves of ivy turned also about it.

All distinct objects are to be made imperfect, as they appear to the eye.

In painting flesh, the following are the best directions for preparing your work so as afterwards more readily to produce the effects of colours seen in nature:

Take flesh-white and a little lake, blend them together, and with that lay the ground-colour; then shade with red-ochre, cherry-stone black, and a little lake, mixed together, touching the lips, cheeks, &c., with a tint of carmine, and heighten the flesh with white and a little carmine. Remember that you can never heighten it with pure white, which will always give it a cold appearance.

The peculiar management of tints in the representation of other various kinds of objects, such as animals, flowers, fruits, &c., will require some attention from the student, but is unnecessary to be given here in detail, as practice will soon instruct him in all that is requisite on this head.

It may be recommended to the student in general, whatever is the subject of his drawing, not to finish any one object first, but to work up every part gradually alike, and be-
From C. Squire, Watermen. A water-course does not begin by prescription, nor assent, but begins by nature, having this course naturally, and cannot be diverted.

3 Bulst. 340.

WATERMEN. In London the lord mayor and court of aldermen have much power in licensing the company of watermen, and appointing the fares for plying on the river Thames; and justices for Middlesex, and other adjoining counties, have also power to hear and determine offences, &c. 10 G. L. II. c. 31.

WATER-SPOUT, an extraordinary aqueous meteor, most frequently observed at sea. It is a truly formidable phenomenon, and is indeed capable of causing great ravages. It commonly begins by a cloud, which appears very small, and which mariners call the squall; which augments in a little time into an enormous cloud of a cylindrical form, or that of a reversed cone, and produces a noise like that of a brisk sea, sometimes emitting thunder and lightning, and also large quantities of rain or hail, sufficient to inundate large vessels, overcast trees and houses, and every thing which opposes its violent impetuosity. These water-spouts are most frequent at sea than by land; and sailors are so convinced of their dangerous consequences, that when they perceive their approach, they frequently endeavour to break them by firing a cannon before the ship. They have also been known to commit great devastations by land; though, where there is no water near, they generally assume the form of a tornado. To enable the reader to understand their nature, we shall preface the different theories by a short description of one of these wonderful appearances, as given by the celebrated M. Tonnet, in安全隐患的Voyant:

"The first of these," says this traveller, "that we saw, was about a musket-shot from our ship. There we perceived the water began to boil, and to rise about a foot above its level. The water was agitated, and fluctuated; and at least there seemed sufficient to stand a smoke, such as might be imagined to come from wet straw before it begins to blaze. It made a sort of murmuring sound, like that of a torrent heard at a distance, moved, at the same time, with a lashing noise, like that of a serpent: shortly after we perceived a column of this smoke rise up to the clouds, at the same time whirling about with great rapidity. It appeared to be as thick as one's finger, and the latter sound still continued. When this disappeared, lasting for about eight minutes, upon turning the opposite quarter of the sky, we perceived another, which began in the manner of the former, and indeed in the same manner rose to the west; and instantly beside it still another arose. The most distant of these three could not be above a musket-shot from the ship. They all continued thus for many hours, and yet continued to move and to make the same noise as before. We soon perceived each, with its respective canal, mounting up in the clouds; and spreading, where it touched the cloud, like a trumpet, filling a figure, to exhibit in a manner press intelligibly, as if the tail of an animal was pulled at one end by a weight. The canals were of a whitish colour, and so tinged as I suppose, by the water which was contained in them; for, previous to this, they were apparently empty; and of the colour of transparent glass. These canals were not straight, but bent in some parts, and far from being perpendicular, but rising in their clouds with an inclination; but what is very particular, the cloud to which one of them was pointed happening to be driven by the wind, the spout still continued to follow its motion without being broken; and passing behind one of the others, the spouts crossed each other, in the form of a St. Andrew's cross.

In the beginning they were all about as thin as a man's finger, except at the top, where they were broader, and two of them disappeared, but shortly after the last of the three increased considerably, and its canal, which was at first so small, soon became as thick as a man's arm, then as his leg, and at last thicker than the whole body. We saw distinctly through this transparent body, the water, which rose up with a kind of spiral motion; and it sometimes diminished a little of its thickness, and again resumed the same; sometimes widening at top, and sometimes at bottom; exactly resembling a gut filled with water, pressed with the fingers, to make the fluid rise or fall. And I am well convinced that this alteration in the spout was caused by the wind, which pressed the cloud, and compelled it to give up its contents. After some time its body diminished no thicker than the man's arm again, and thus swelling and diminishing, it at last became very small. In the end I observed the sea which was raised.
WAT

This is a page from a book discussing the phenomenon of whirlwinds and water-sprouts. The text describes how these phenomena are observed and the interactions between the whirlwinds and water bodies, leading to the production of electricity. The author, Mr. Oliver, who is referenced in the text, has developed a theory that explains the phenomenon. The text is a part of a larger experiment conducted by Capt. Bostock, which was assisted by Dr. Pearson and has been verified by Dr. Bouck. The water-sprout is a natural process that occurs under various conditions, and the wax produced is a byproduct of the process. The wax is described as being insoluble in water and having a specific gravity of 0.9609. Wax is also mentioned as a possible ingredient in the composition of beeswax.

The text concludes with a discussion on the effect of heat on wax, where it is stated that wax is not affected by heat. The wax produced in this manner is considered useful for making candles.

The text is a part of a larger work on natural phenomena and their interactions with the environment, particularly focusing on the production of electricity and the formation of water-sprouts.
which is known by the name of cerate, is much employed by surgeons. The volatile oils also dissolve it when heated. This is well known, at least, to be the case with oil of turpentine. A part of the wax precipitates usually as the solution cools, but of a much softer consistence than usual, and therefore containing oil.

The fixed alkalies combine with it, and form a compound which possesses all the properties of common soap. When boiled with a solution of fixed alkalies in water, the liquid becomes turbid, and after some time the soap separates and swims on the surface. It is precipitated from the alkali by acids in the state of flake, which are the wax very little altered in its properties. Punic wax, which the antients employed in painting in encaustic, is a soap composed of 20 parts of wax and one of soda. Its composition was ascertained by Mr. Lorgna.

When boiled with liquid ammonia, it forms a kind of soapy emulsion. As the mixture cools, the greatest part of the compound rises to the surface in the state of white flakes. This soap is a perfectly soluble in water.

The acids have but little action on wax; even oxycurric acid, which acts so violently on most bodies, produces no other change on it than that of rendering it white. This property which wax possesses, of resisting the action of acids, renders it very useful, as a lute, to confine acids properly in vessels, or to prevent them from injuring a common cork.

Mr. Lavoisier, by means of the apparatus which he employed in the analysis of alcohol and coal, could burn wax in oxygen gas. The quantity of wax consumed was 21.9 grams. The oxygen gas employed in consuming that quantity amounted to 66.55 grams. Consequently the substances consumed amounted to 88.45 grams. After the combustion, there were found in the glass vessel 62.58 grams of carbonic acid, and a quantity of water which was supposed to amount to 21.97 grams. These were the only products.

Now 62.58 grams of carbonic acid gas contain 44.56 of oxygen, and 18.02 of carbon; and 21.97 grams of water contain 21.99 of oxygen, and 3.88 of hydrogen.

Consequently 21.9 parts of wax are composed of 18.02 of carbon and 3.88 of hydrogen. And 100 parts of wax are composed of 82.28 carbon and 17.72 hydrogen.

But this analysis can only be considered as an approximation to the truth; the quantity of water being only estimated, and that of the gas being liable to uncertainty. There can be no doubt, from the little action of acids on wax, that it contains oxygen as an ingredient. We must therefore consider it as a triple compound of carbon, hydrogen, and oxygen; but the proportions are unknown.

WAX.

If wax is distilled with a heat greater than 212°, there comes over a little water, some acid, and a little smoke. From this oil, as the distillation advances, becomes thicker and thicker, till at last it is of the consistence of butter, and for this reason has been called butter of wax. There remains in the retort a fixed oil which is not easily reduced to ashes. When the butter of wax is repeatedly distilled, it becomes very fluid, and assumes the properties of volatile oil.

Wax possesses all the essential properties of fixed oil. We must therefore consider it as a fixed oil rendered concrete. Now that species of fixed oils, distinguished by the epitaph fat, have the property of becoming concrete, and assuming the appearance of wax when exposed long to the air; in consequence, it is supposed, of the absorption of oxygen. Hence probably the difference between wax and fixed oils consists in the oxygen which it contains as a component part. The wax at first from the state of a fixed oil; but by the absorption of oxygen it gradually concretes into wax. Wax, then, may be considered as a fixed oil saturated with oxygen.

It is natural to suppose, if this theory is just, that fixed oils occur in plants in various states of hardness: and this accordingly is the case. Sometimes it is of the consistency of butter, and this is denominated a butter; thus we have the butter of cacao, the butter of coco, the butter of galam. Sometimes it is of a greater consistency, and then is denominated tallow; than we have the tallow of the croton, extracted by boiling water from the fruit of the croton seiblera. When its consistency is as great as possible, it then takes the appellation of wax. Thus we have the myrtle wax of America extracted from the berries of the myrica cerifrera, and the pears of the Chinese. The species of wax, then, which exist in the vegetable kingdom, may possibly be as numerous as the fixed oils. Let us take a view of some of the most remarkable.

Bees' wax is the species whose properties have been most studied in the foregoing article. It is supposed that the bees collect it from plants; but it has been very well ascertained, that in many cases at least they manufacture it from honey, and even from sugar: for bees confused and fed solely upon these substances produce wax. Its consistence is said to be less when the bees are confined to sugar than when they are allowed honey.

The myrtle wax of North America is obtained from the myrica cerifrera. We are indebted to Dr. Bostock and Mr. Cadet for a very exact account of its properties and extraction. The myrica cerifrera is a shrub which grows abundantly in Louisiana and other parts of America. It bears a berry about the size of a pepper-corn. A very fertile shrub yields nearly seven pounds. The berries are picked off, thrown into a kettle, and covered with water to the depth of half a foot. The kettle is then boiled, and the berries stirred and squeezed against the sides of the vessel. The wax which they contain is melted out and swims on the surface. It is skimmed off, passed through a cloth, dried, melted again, and cast into cakes. From the observations of Cadet we learn that the wax forms the outer covering of the bee, and that thus obtained is a pale green colour. Its specific gravity is 1.0150. It melts at the temperature of 109°; when strongly heated it burns with a white flame, produces little smoke, and during the process emits a disagreeable aromatic colour. Water does not act upon it. Alcohol, when hot, dissolves 9/10th of its weight but leaves most of it fall again on cooling.

Wax Crayons. The art of painting in wax crayons is a late discovery, and when first employed of producing the most pleasing effect. It is, however, to be considered as an adjunct to the art of water-colours, than as a distinct branch of the art of design or painting, as will appear from the nature of the materials employed in it. Instead of the substances used in conjunction with the respective colours, to form the body of common crayons, such as plasters of Paris, pipe-clay, calcined albaaster, &c. all the coherents used in this mode of painting are to be incorporated with wax. This mixture gives them the superior advantage of being particularly calculated for the execution of minute works in crayons, as they are not liable to mould or adhere, or to be rubbed off from the paper; but works thus executed require the assistance of various washes in water-colours to improve and perfect their effect, as from the nature of wax, the frequent works of these crayons would produce an excessive smoothness, or glassiness, which would prevent the colours from attaching or taking proper hold of the surface of the work in the heightenings and last finishings, and would disappoint the artist in his endeavours to produce the greatest requisite strength of effect.

It is to be observed, therefore, that water-colours are to be used in beginning your picture, and in finishing it. When the crayons are judiciously worked over the water-colours, they will produce the appearance of an elegantly finished stippled engraving, coloured in the plate; the grain of the paper catching the crayons in dots, (when gradually laid on with the finger, and with a light hand) in a wonderfully pleasing manner.

We shall comprise the instructions requisite for the student’s practice under the following heads, namely:

1. The kind of wax to be used in making the crayons;
2. The colours fit to be incorporated with it;
3. The choice of proper paper;
4. The method of using the crayons.

Wax. The wax proper to be used in making crayons, must be bleached bees’ wax, entirely free from adulteration. It must likewise be of the hardest kind, of which the Russian wax is the best, although in colour not quite so fine as either the American or English wax; but its hardness gives a firmness to the crayons, and prevents a greasiness which other waxes would create.

Colours. The colours proper for mixing into crayons, are the following, viz. for yellows, king’s yellow or yellow ocher; for blues, Antwerp or Prussian; for reds, cinnabar; and Chinese vermilion; for browns, tobacco, burnt and unburnt; for blacks, lampblack.
only. As to compound tints, they are to be produced by a judicious management of the water-colours over the crayons; and this rule with respect to the colours proper to be used for crayons, as to their being carefully observed, that none are fit for the purpose, but such as, in their dry unmixed state, will mark on paper fairly well: for the reader may easily judge, that the tenacity of the wax would completely prevent any kind of colour from working that was incorporated with it.

Having procured the kind of wax already mentioned, you are to have a nice glued white paper, perfectly clean and free from any greasy particles; and having previously ground your colours on a flag with your mallet, perfectly fine, in fair water, and dried, put a small quantity of wax into the paper, which you are to place over a very slow fire; when the wax is entirely dissolved by the gentle heat (for if it bubbles it is spoiled), gradually work in your colour, stirring it with an ivory pencil-handle, until you find it perfectly mixed; at the same time observing that you do not overload the wax with colour, as it will make your surface too thick for you to work in; and you are to put in too little colour, as it will make it faint and work greasy; so a medium is to be observed, to ascertain which practice only will conduce. There are some colours, such as vermilion, which, if they receive too great a heat, turn black, and that must be very cautiously observed, in this kind of painting, as a highly useful colour: as is also lamp-black, a harder kind from which it must be used, as it may be made by mixing some of it, in its raw state, with strong glue, letting it harden, and then burning it in a crucible (as directed in calcining colours for miniature painting); then pulverizing it on your flag, and mixing it with your wax, as before mentioned. This kind of black crayon is most excellent for giving sharp touches in dark parts, as it is well adapted for making sketches to refresh the memory: is much superior to black chalk, as nothing will cause it to rub or spoil, it remaining as immovable as writing-ink, and working extremely pleasant.

Paper. The paper fit to be used in wax-crayon painting, must be of the wove or velum kind, but as there are several that are too fine, the grain will catch the crayons in dots so remote from each other, as to make your work look unpleasant; and if the paper is too fine it will not catch the crayons as it ought, but clog your painting without producing any effect. The only rule therefore for choosing your paper is to go to the stationer's, and taking a small bit of soft black crayon, by gently rubbing the crayon on a few sheets of different kinds of wove paper, you will become a judge of what is the best for your purpose, at a trifling expense. Having procured this necessary article to your satisfaction, you are to work on it at your leisure.

Method. The desk you are to work on must be much larger than the one mentioned for miniature painting, (see Miniature,) this kind of work being often used for larger sizes than the style of painting here mentioned, where the effects are more delicate; hence you are to place it in the same manner as pointed out in the article on Miniature Painting, with a soft piece of charcoal sketch faintly the distances and forms of the features; then touch in them more strongly with your crimson or black crayon, still altering until you are perfectly certain you have a correct outline. Inasmuch as the kind of painting is absolutely necessary; for in your fair drawing you commit an error in your outline, you never can alter it, the crayons being in their nature so adhesive, that nothing will remove them. Having, on your first sheet, made your outline correct, rub the back of the face part with crimson crayon, the hair part with a suitable-coloured one, and the drapery, if white, with black; then laying the paper on a fair sheet go over the outlines of your sketch with a tracer, when you will transfer, in a very neat manner, your outline ready to colour in.

You are then to mark in the features of your sitter more strongly with crimson or water-colour, and a fine pencil; ever observing, when you use it, to work over with a suitable-coloured crayon, as it is that which will give the beautiful dotted appearance so much to be admired.

Having marked in the features sufficiently strong to put the likeness out of danger of being spoiled, make a wash of yellow or entire over the flesh parts, deepening its tint according to your subject; wash-in the colour of the lips, hair, and black being dry, work with your different-coloured crayons on the parts, until you produce the effects required; filling up any interstices of the crayons with dots of water-colours and a fine wash. As to the tint of your lime shades, the black crayon will produce that in every degree, the paper answering for the lights of any-coloured drapery; for then you are to wash-in and shadow it with the crayons. Your paper is to be perfectly dry, otherwise the work will appear glazy; but even should that be the case, hold it before the fire, and the shining appearance will instantly vanish.

With respect to your back grounds, as this style of painting is intended to be light and sketchy, and back grounds are to be preferred; to manage which, the best way is to stumpl in them with dry colour, to what extent you find pleasing, and in a proper state, to add a proper value to the appearances of your wax crayons. Your drawing, either of portrait or landscape, being finished, have ready a large flat board, on which you are to stretch a sheet of royal paper; and having pasted the back of your drawing with some flour paste mixed with sizing, lay it on the royal paper, and carefully press it in all directions with a soft towel or handkerchief, when your work is completed.

WAY. A way may be by prescription, as if the owners and occupiers of such a farm have immemorially used to cross another's ground; for this immemorial usage supplies an original grant. A right of way may also arise by act and operation of law; for if a man grants to another a piece of ground in the middle of his field, he at the same time tacitly gives him a way to come at it, for where the law gives any thing to any person, it gives implied whatever is necessary for enjoying the same. 2 Black 33.

WAY of a ship, is sometimes used for her wake or track. But more commonly the term, way, is used to denote the progress, or the impression to which she makes on the water under sail; thus when she begins her motion, she is said 5 X 2 to be under way; when that motion increases, she is said to have fresh way through the water; when she goes space, they say she has a good way; and the account of having the ship lying by the log, they call, keeping an account of her way. And because most ships are apt to fall a little to the leeward of their true course, it is customary, in casting up the log-board, to allow something for her leeward way, or lee way. Hence also a ship is said to have head-way, and stern-way.

WAYFITES, or WAITS. This noun formerly signified halloo boys; and, which is remarkable, has no singular number. From the instruments its signification was, after a time, transferred to the performers themselves; who being in the habit of parading the streets by night with their music, occasioned the name to be applied generally to all musicians who followed a similar practice. Hence those persons who annually, at the approach of Christmas, salute us, with their nocturnal concerts, were, and are to this day, called wayfites.

WAY WISER, an instrument for measuring the road, or distance travelled; called also PERAMBULATOR, and PEDOMETER. See those two articles.
It appears from the construction of this machine, that it operates like circular compasses; and does not, like the common wheel way-wiser, measure the surface of every stone and round bush, but passes over most of the obstacles it meets with, and measures the chords only, instead of the arcs of any curved surfaces upon which it rolls.

WEASEL. See VITERRA.

WEATHER. See Meterology.

Weather-glasses, are instruments constructed to indicate the state or disposition of the atmosphere, and the various alterations in the weather: such as barometers, thermometers, hygrometers, &c.

WEAVERS. The wages of journeymen weavers in London are to be settled by the lord mayor, recorder, and aldermen. Masters giving more wages than is appointed, to forfeit 50l. and journeymen demanding, or combining to demand more, to forfeit 40s. or be imprisoned three months.

WEAVING-LOOM. See LOOM.

WEB, a tissue, or texture, formed of threads with each other: some whereby are extended in length, and called the warp; and others drawn across, and called the woof. See WARP, &c.

WEBER, See Trachinus.

WEIGELLA, a genus of plants of the class and order pentandria monogynia. It is cultivated; the single, two-celled, cells; stigma club-shaped; calyx five-cleft. There are three species, shrubs of the East Indies.

WEEVER. See Trachinus.

WEIGHT, WAY, or WEG, unga, a weight of cheese, wool, &c. containing 256 pounds avoirdupois. Of corn, the weight contains forty bushels; of barley or malt six quarters. In some places, as Essex, the weight of cheese is 300 pounds.

WEIGHT, gravity, in physics, a quality in all bodies whereby they tend downwards, towards the centre of the earth. Or weight may be defined in a less limited manner, to be a power inherent in all bodies whereby they tend to some common point, called the centre of gravity; and that with a greater or less velocity, as they are more or less dense, or as the medium they pass through is more or less rare.

In the common use of language, weight and gravity are considered as one and the same thing. Some authors, however, make a difference between them, and hold gravity only to express a pull, or endeavour to descend, but weight an actual descent. But there is room for a better distinction. In effect, one may conceive gravity to be the quality as inherent in the body; and weight the same quality, exerting itself either against an obstacle, or otherwise. Hence, weight may be distinguished, like gravity, into absolute and specific. See Gravity.

Sir Isaac Newton demonstrates, that the weight of all bodies, at equal distances from the centre of the earth, are proportional to the quantities of matter each contains. Whence it follows, that the weights of bodies have not any dependence on their forms or textures: the spaces are not equally full of matter. Hence also it follows, that the weight of the same body is different on the surface of different parts of the earth, as its figure is not a sphere, but a spheroid.

WEIGHT, pondus, in mechanics, is any thing to be raised, sustained, or moved by a machine, or any thing that in any manner resists the motion to be produced.

WEIGHT, in commerce, denotes a body of a known weight, appointed to be put in the balance against other bodies, whose weight is required.

The security of commerce depending, in good measure, on the justness of weights, which are usually of lead, iron, or brass, most nations having taken care to prevent the falsification of them, by stamping or marking them by proper officers, after being adjusted by some original standard. Thus in England, the standard of weights is kept in the exchequer, by an officer, called the clerk of the market.

WEIGHTS and MEASURES, regulation of. This is a branch of the king's prerogative. For the public convenience, those ought to be universally the same throughout the nation, the better to reduce the prices of articles to equitable values. But as we measure things in their nature arbitrary and uncertain, it is necessary that they are reduced to some fixed rule or standard. It is, however, impossible to fix such a standard by any written law or oral proclamation; as no person can, by words only, give to another an adequate idea of a pound weight, or foot rule. It is therefore expedient to have recourse to some visible, palpable, material standard, by forming a comparison with which all weights and measures may be reduced to one uniform size. Such a standard was antiently kept at Winchester; and we find in the laws of King Edgar, near a century before the Conquest, an injunction that that measure should be observed throughout the realm.

Most nations have regulated the standard of measures of length from some part of the human body; as the palm, the hand, the span, the foot, the cubit, the ell (shut or arm), the pace, and the fathom. But as these are of different dimensions in men of different proportions, antient historians inform us, that a new standard of length was fixed by our king Henry the First; who commanded that the ell, or antient ell, which answers to the modern yard, should be made of the exact length of his own arm.

A standard of long measure being once gaining, all others are easily derived from it; those of greater length by multiplying that original standard, those of less by dividing it. Thus, by the statute called composito chartarum of tertiam, 55 yards make a perch; and the yard is subdivided into three feet, and each foot into twelve inches, and the inch is divided into thirty-two points, which are each of the length of three barleycorns. But some, on the contrary, derive all measures by composition, from the barleycorn.

Superficial measures are derived by squar-

---

The Roman ounce is the English avoirdupois ounce, which they divided into seven darms, as well as eight drachms; and since they reckoned their denarius equal to the Attic drachm, this will make the Attic weights one-eighth heavier than the corresponding Roman weights.

Writhe, *Modern European. 1. English weights.* By the twenty-seventh chapter of Magna Charta, the weights all over England are to be the same; but for different commodities, there are two different sorts, viz. Troy weight and avoirdupois weight. The origin from which they are both raised, is a grain of weight gathered in the middle of the ear.

In Troy weight, twenty-four of these grains make a pennyweight sterling; twenty pennyweights make one ounce; and twelve ounces make one pound.

By this weight we weigh gold, silver, jewels, grains, and liquors. The apothecaries also use the Troy pound, ounce, and grain, but they differ from the rest in the intermediate divisions. They divide the ounce into eight drachms; the drachm into three scruples, and the scruple into twenty grains.

In avoirdupois weight, the pound contains sixteen ounces, but the ounce is less by near one-twelfth than the Troy ounce; this latter containing 490 grains, and the former only 448.

The ounce contains 16 drachms; 80 ounces avoirdupois are only equal to 73 ounces Troy; and 17 pounds Troy equal to 14 pounds avoirdupois.

By avoirdupois weight are weighed mercury, and grocery ware, base metals, wood, tallow, hemp, drugs, bread, &c.

---

In addition to certain weights peculiar to themselves: thus, Spain has its arroba, containing 25 Spanish pounds, or one-fourth of the common quintal; its quintal macho, containing 156 pounds, or one-half common quintal, or 6 arrobas; its alhumbre, containing one-sixteenth of its ounce. And for gold, it has its castilla, or one-hundredth of a pound, and its toncini, containing 12 grains, or one-sixtieth of a castilla. The same are in use in the Spanish West Indies.

Portugal has its arroba, containing 39 Lisbon arrobas, or pounds; Savary also mentions its farżelette, containing 2 Lisbon pounds; and its rototillo, containing about 12 pounds. And for grains, its choppo, containing 4 quartos. The same are used in the Portuguese East Indies.

Italy, and particularly Venice, have their migliaro, containing four mirtres; the mirre containing 30 Venice pounds; the taglio, containing a sixth part of an ounce. Genoa has five kinds of weights, viz. large weights, whereby all merchandise are weighed at the custom-house; cash weight, for grains, other specie, the canarino, or quintal, for the coarsest commodities; the large balance for raw silks, and the small balance for the fine commodities. Sicily has its rotolo, 92 and a half pounds of Messina.

German.

71 lbs. or grs. English troy = 74 lbs. or gr. German apothecaries' weight.

1 oz. Nuremberg, medic. weight, = 7 dr. 2 scr. English.

1 mark Cologne, = 7 oz. 2 dwt. 4 gr. English troy.

Dutch.

1 lb. Dutch = 1 lb. 3 oz. 16 dwt. 7 gr. English troy.

78 lbs. Dutch = 1038 lbs. English troy.

Swedish Weights, used by Bergman and Scler.

The Swedish pound, which is divided like the English apothecary, or troy, pound, weighs 4808.719444 English troy grains, or is equal to 0.8203 English cubic inches; and the Swedish longitudinal inch, is equal to 1389.482 English longitudinal inches.

From these data, the following rules are deduced:

1. To reduce Swedish longitudinal inches to English, multiply by 0.8203, or divide by 1.2189.

2. To reduce Swedish to English cubic inches, multiply by 1.8, or divide by 0.5557.

3. To reduce the Swedish pound, ounce, dram, scruple, or grain, to the corresponding English Troy denomination, multiply by 1.2189, or divide by 0.8203.

4. To reduce the Swedish Kenny to English wine grains, multiply by 1.2189, or divide by 0.8203.

5. The troy, a weight sometimes used by Bergman, is the 32d part of the Swedish pound: Therefore, to reduce it to the English troy pound, multiply by 0.03577, or divide by 28.1126.

Correspondence of English Weights with those used in France before the Revolution.

The Paris pound, poids de marc of Charlemagne, contains 9216 Paris grains; it is divided into 16 ounces, each ounce into 8 gros, and each gros into 72 grains. It is equal to 7361 English troy grains.

The English troy pound of 12 ounces contains 2437.84 grains.

The English avoirdupois pound of 16 ounces contains 7000 English troy grains, and is equal to 4808.719444 English.

To reduce Paris grains to English troy grains, divide by 0.8203.

To reduce English troy grains to Paris grains, multiply by 0.8203.

Weights used in the several parts of Asia, the East Indies, China, Persia, &c. In Turkey, at Smyrna, &c. they use the batman, or battenm, containing six reises, the ounce, weighing three pounds four-fifths English. They have another battenmuch less, consisting of the former, of six oozes; but the ounce only containing fifteen English grains; 44 oozes of the first kind make the Turkish quintal. At Cairo, Alexandria, Aleppo, and Alexandria, they use the roto, rotton, or rottol; at Cairo, and other parts of Egypt, it is 144 draks, being somewhat over an English pound. At Aleppo they have three sorts of rottos; the first 720 draks, making about seven pounds English, and serving to weigh cottons, galls, and other large commodities; the second is 624 draks, used for all silks but white ones, which are weighed by the third rotto of 700 draks. At Smyrna the rotto is 600 draks.

The other parts of the Levant, not named here, use some of these weights, particularly the ooz, or occult, the rottol, and the rotto.

The Chinese weights are the piece, for large commodities; it is divided into 100 cats, or cattis, though some say into 125; the piece into 16 cats, or taels, each tael equivalent to 1 1/2 of an ounce English, or the weight of one rial and 9/10, and containing 12 mas, or masses, and each mas 10 condins. So that the Chinese piece amounts to 137 pounds English avoirdupois, and the cati to 1 pound 8 ounces. The piece for silk contains 66 cats and 2/10 the bahar, balseire, or barr, contains 300 cats.

Tonquin has also the same weights, measure, &c. as China. Japan has only one weight, viz. the seer, or seerf, which is different from that of China, as containing different numbers of taels. At Surat, Agra, and throughout the states of the Great Mogul, they use the man, or muns, wherein they have two kinds, the king's man, or man, of weight, and the man simply; the first used for the weighing of common provisions, containing 40 seers, or seers, and each seer a just Paris pound. The common man, used in the weighing of merchandise, consists likewise of 40 seers, but each seer is only estimated at 19 Paris ounces, or 2/10 of the other seer.

The man may be looked on as the common weight of the East Indies, though under some difference of name, or rather of pronunciation, it being called muzo at Cambay, and in other places meen, and maun. The seer is properly the Indian pound, and of universal use; the like may be said of the bahar, tael, and cati above-mentioned.

The weights of Siam are the piece containing two shans, or cattis; but the Siamese catti is only half the Japanese, the latter containing 20 taels; and the former only 10; though some say, that the siamese catti only 10 taels, and the Siamese 8. The tael contains 4 baats or ticals, each about a Paris ounce; the baat 4 seels, or mayors; the mayor 2
WEI

found; the foung 4 pays; the puye 2 claws; the sompaye half a foung and nine.
In Golconda, and Goa, they have the funtrule containing 1 pound 14 ounces English; the mangelus or mangolin for weighing diamonds and precious stones, weighing at Goa's grains, at Golconda. They say little about the rotole containing 144 ounces English; the metrical containing the sixth part of an ounce; the wall for piasters and ducats, containing the 73rd part of a rial.

In Persia they use two kinds of hammers or maws, the one called cali or cherary, which is the king's weight; and the other batman of Tauris. The first weighs 13 pounds 10 oz. English; the second 64 pounds, its divisions are the ratel, or a 10th; the derhem, or drachm 20 tin; the bunch, which is half the derhem; the dung, which is the 6th part of the meschal, being equivalent to six carat-grains; and, lastly, the grain, which is the fourth part of the dung. They have also a light and a heavy ounce; the salt-cherary, equal to the 1170th part of the derhem; and the toman, used to weigh out large payments of money without telling; its weight is that of 50 avoirdupois.

African and American weights. We have little to say as to the weights of America; the several European colonies there making use of the weights of the states or kingdoms of Europe they belong to. For, as to the auro of Peru, which weighs 57 pounds, it is evidently no other than the Spanish arroba, with a little difference in the name.

As to the weights of Africa, there are few places that have any, except Egypt, and the countries bordering on the Mediterranean, whose weights have been already enumerated among those of the ports of the Levant. The island of Madagascar indeed has weights, but none that exceed the drachm, nor are they used for anything but gold and silver.

WIGHTS and MEASURES of measurement are kept at Winchester, which measure was by the law of King Edgar, ordained to be observed through the kingdom.

By. stat. 35 G. III. c. 105, the justices in quarter-sessions in every county, are required to appoint persons to examine the weights and balances within their respective jurisdictions. These inspectors may seize and examine weights in shops, &c. and seize false weights, and, if the offender, being convicted before one justice, shall be fined from 5s. to 20s. Persons obstructing the inspectors to forfeit from 5s. to 40s. Inspectors to be recompensed out of the county-rate. Such buses as are purchased by the sessions out of the county-rate, and produced to all persons paying for the production thereof. Informations to be within one month.

Universal standard for weights and measures. In case the transactions of one country be to be purchased by the sessions out of the county-rate, and produced to all persons paying for the production thereof. Informations to be within one month.

Universal standard for weights and measures. In case the transactions of one country be to be purchased by the sessions out of the county-rate, and produced to all persons paying for the production thereof. Informations to be within one month.

The universal standard for weights being once established, those of weights, &c. would easily follow. For instance: a vessel, of certain dimensions contains a certain weight of distilled water, or some other homogenous matter, the weight of that may be considered as a standard for weights.

WELMENNA, a genus of plants of the class and order octandria linnaceae. The calyx is four-leaved; corolla four-petalled; caps. two-celled, two-beaked. There are six species, trees of the southern climates.

WELDING HEAT, is smithey, a degree of heat given to iron, &c. sufficient to make any two bars or pieces of iron unite by a few strokes of the hammer, and form one piece.

See IRON.

WEN. See SURGERY.

WESTRINGA, a genus of plants of the family gymnossperma class and order. The calyx is half five-cleft, five-sided; corolla reversed; four segments, longest erect; clawed, stam. distant, two shorter abortive. There is one species, a shrub of New South Wales.

WHALE. See BALENA.

WHEAT. See TRITICUM, and Hus.

BANDERY.

WHEAT-FAR. See MOTACILLA.

WHEELE, in mechanics, a simple machine, consisting of a round piece of wood, metal, or other matter, which revolves on an axis. The wheel is one of the principal mechanical powers; it has place in most engines; little of it is used in an assemblage of wheels that most of our engines are composed. See MECHANICS.

Wheels, of couches, carts, waggon, &c. With respect to wheels of carriages, the following particulars are collected from the experiments and observations of Desaguliers, Brighton, Camus, Ferguson, Jacob, &c.

1. The use of wheels in carriages is twofold, viz. that of diminishing or more easily overcoming the resistance or friction of the carriage; and that of more easily overcoming obstacles in the road. In the first case, the friction on the ground is transferred in some degree from the wheel to the axle; and in the latter, they serve easily to raise the carriage over obstacles and asperities not met with on the roads. In both these cases, the height of the wheel is of material concern. The spokes act as levers, the tops of an obstacle, being the fulcrum, their length enables the carriage more easily to surmount them; and the greater proportion of the wheel to the axle serves more easily to diminish or to overcome the friction of the axle.

2. The wheels should be exactly round; and the felices at right angles to the naves, according to the inclination of the spoke.

3. It is in the most general opinions, that the spokes are somewhat inclined to the nave, so that the wheels may be disuing or concave. Indeed if the wheels were always to roll upon smooth and level ground, it would be best to make the spokes perpendicular to the nave, so as to prevent the weight from being totally on the axle, and to diminish the friction of the axle.

4. But because the ground is commonly uneven, one wheel often falls into a cavity or rut, when the other does not, and then it bears much more of the weight than the other does;
in which case it is thought best for the wheel to be dished, because the spokes become perpendicular in the rut, and therefore have the greatest strength when the obliquity of the direction of the weight and the weight itself are perpendicular; whilst those on the high ground have less weight to bear, and therefore need not be at their full strength.

4. The axles of the wheels should be quite straight, and perpendicular to the shafts, or to the pole. When the axles are straight, the rims of the wheels will be parallel to each other, in which case they will move the easiest, because they will be at liberty to proceed straight forwards. But in the usual way of practice, the ends of the axles are bent downwards, which always keeps the sides of the wheels that are next the ground nearer to one another than their upper sides are; and this not only makes the wheels drag sideways as they go along, and gives the load a much greater power of crushing them than when they are parallel to each other, but also endangers the overturning the carriage when a wheel falls into a hole or rut, or when the carriage goes on a road that has one side lower than the other, as along the side of a hill.

Large wheels are found more advantageous for ordinary purposes than small ones, both with regard to their power as a lever longer, and to the degree of friction, and to the advantage in getting over holes, rubs, and stones, 

If we consider wheels with regard to the friction upon which they are applied, it is evident that small wheels, by turning sooner round, and swifter about the axles, than large ones, must have more friction. Again, if we consider wheels as they sink into holes or soft earth, the large wheels, by sinking less, must be more easily drawn out of them, as well as over stones and obstacles, from their greater length of lever or spokes.

It is a fact, however, that the draught ought not to be horizontal, but rather inclined: because in the horizontal draught the collar presses against the chest of the horse, instead of bearing on his shoulders, as in an inclined draught; and because in this latter circumstance, the wheels press more easily over obstacles than when the draught is horizontal.

Hence it appears, that wheels are the more advantageous as they are larger, provided they are not so high as to make the draught horizontal; and that when they are very large also, they become too heavy; or if they are made light, their strength is proportionally diminished, and the length of the spokes renders them more liable to break; besides, horse—applied to such wheels would not be capable of exerting their utmost strength, for the reasons already assigned, small wheels occasing the horses to draw upwards.

6. Carriages with four wheels, as waggons or coaches, are much more advantageous than carriages with two wheels, as carts and chaises: for with two wheels it is plain the tilter—horse carries part of the weight, in one way or other; in going down hill, the weight bears upon the horse; and in going up hill, the weight falls the other way, and hits the horse, which is still worse. Besides, as the wheels sink into the holes in the road, sometimes on one side, sometimes on the other, the tilter—horse, with the tilted sides, which destroys many horses: moreover, when one of the wheels sinks into a hole or rut, half the weight falls that way, which endangers the overturning of the carriage.

7. It would be much more advantageous to make the four wheels of a coach or waggon nearly of the same height, than to make the fore—wheels of only half the height of the hind wheels, as is used in many places. The fore—wheels have commonly been made of a less size than the hind ones, both on account of turning short, and to avoid cutting the braces. Crane—necks have also been invented for turning yet shorter; and the fore—wheels have been lowered, so as to go quite under the bend of the crane—neck.

When a horse draws hard, it is observed through the beams forward, and brings his breast near the ground, and then if the wheels are high, he is pulling the carriage against the ground. A horse tackled in a waggon will draw two or three ton, because the point of line of action is below his breast, by the lowness of the wheels. It is also common to see, when one horse is drawing a heavy load, especially up hill, his fore feet will rise from the ground; in which case it is usual to add a weight to the horse's head to keep him down, by a person mounting on his back or shoulders, which will enable him to draw that load which he could not move before.

The greatest stress, or main business of drawing, is to overcome the resistance of the air; and as the drawing is but little, and then the horse's back need be pressed but with a small weight.

8. The utility of broad wheels, in amending and preserving the roads, has been so much insisted on, that it has been recommended by many legislators to enforce their use. At the same time, the proprietors and drivers of carriages seem to be convinced by experience, that a narrow—wheeled carriage is more easily and speedily drawn by the same number of horses, than a broad—wheeled one of the same burden; probably because they are much lighter, and have less friction on the axle; and brought wheels will always be lighter than broad wheels.

WHEREAS it is evident, that there is a genus of animalculae which have an apparatus of arms for taking their prey. This apparatus has been supposed, by microscopic writers, to be a kind of wheels; and they thence named the creatures that are possessed of it, wheel—animals.

WHIRLPOOL, an eddy, vortex, or whirl, where the water is continually turning round. These in rivers are very common, from various accidents, and are usually very trivial, and of little consequence. In the sea they are more rare, but more dangerous. Sibbald has related the effects of a very remarkable strain of the whirlpool called the Orcades, which would prove very dangerous to strangers, though it is of no consequence to the people who are used to it. This is not fixed to any particular place, but appears in various parts of the coast of the sea among those islands. Wherever it appears, it is very furious; and boats, &c. would inevitably be driven in and perish with it; but the people who navigate them are prepared for it, and always carry an empty vessel, a log of wood, or large bundle of straw, or some such thing, in the boat with them; as soon as they perceive the whirlpool, they toss this within its vortex, keeping themselves out; this substance, whatever it may be, is immediately received into the centre, and carried under water; and as soon as this is done, the sur— face of the water, which was before the whirlpool, becomes smooth, and they row over it with safety; and in about an hour they see the vortex begin again in some other place, usually at about a mile distance from the first.}

WHIRLWINDS. This phenomenon is well defined by its name. Its nature may be illustrated by recurring to the same kind of motion in a denser fluid. When water is flowing through an aperture in the bottom of a vessel, we may observe that the meeting of the currents which proceed from all sides towards the opening, gives rise at length to a circular motion just over it; at first confined to a small space, but spreading by degrees, until it occupies a large portion of the surrounding water. At this time, the centrifugal force becomes greater every instant, the water absolutely quits the central space, leaving a hole through it, which, together with the whirlpool, continues to maintain the remaining time of the discharge. Now, as the water descends by its gravity, and the other effect depends on a lateral impulse, given by the most powerful of the confluence streams, and the same effect of the particular tract which appears, is due to the greater falling of the water, the whirlpool being the lateral pressure of surrounding colder and heavier air, may at any time give rise to a whirlwind of greater or less extent and force, according to the quantity of water which has been sucked up, and to a higher station, in order that the equilibrium of the atmosphere may be restored. There is wanted, for this purpose only a sudden impulse from some quarter, sufficient to disturb the uniform motion of the ascending stream. The effects of whirlwinds are sometimes tremendous; not only large quantities of hay, and other light bodies, but even the limbs of trees, the roofs of houses, and other ponderous matters, having been lifted up and carried off by them. Their effects are no where more conspicuous than in the vast plains of sand, so much dreaded by travellers; which, as they have the moving surface of the sand, are enabled to form which we have a good account in Bruce's Travels. Dr. Franklin, in whom sagacity of observation was eminently united with the power of simple and plain description, has left us the following account of the whirlwind, of which he was an eye—witness close at hand.

"Being in Maryland (says the doctor) riding with colonel Parker, and some other gentlemen, to his country—seat, we saw in the vale below us a whirlwind, beginning in the road, and swerving itself by the dust it raised and contained; it appeared in the form of a sugar—loaf, spinning on its point, moving up the hill towards us, increasing as it came forward. When it passed by us, its smaller part, near the ground, appeared no bigger than a common barrel, but widening upwards, it seemed at 40 or 50 feet high, to be 20 or 30 feet in diameter. The rest of the company stood looking after it, but my curiosity being stronger, I followed it, riding close by its side, and observed it lipping up, in its progress, all the dust that was under its smaller part. As it rose, it gained strength, and a shot fired through a water—spout will break it, I tried to break 8
this little whirlwind, by striking my whip frequently through it, but without an effect. Soon after it quitied the road, and took into the woods, growing every moment larger and stronger, raising, instead of dust, the old dry leaves, with which the ground was thick-covered, and muffled the noise with the rustling of the and the branches of trees, bending some tall trees round in a circle swiftly, and very surprizingly; though the progressive motion of the whirlwind was not swift, but that a man on foot might have kept pace with it; but the circular motion was amazingly rapid. By the leaves it was now filled with, I could plainly perceive that the current of air they were driven by, moved upwards in a spiral line; and when I saw the passing whirl which came time entire after leaving the trunks and bodies of large trees which it had enveloped, I no longer wondered that my whip had no effect on it in its smaller state. I accompanied it about 3 of a mile, till some limbs or dead trees, broken off by the whirl, flying about, falling near me, made me more apprehensive of danger; and then I stopped, looking at the top of it, as it went on, which was visible, by means of the leaves coming in it, for a very great height above the trees. Many of the leaves, as they got loose from the upper and widest part, were scattered in the wind; but so great was their height in the air, that they appeared no bigger than flies. My son, who by this time was come up with me, followed the whirlwind till it left the woods, and crossed an old tobacco field, where, finding neither dust nor leaves to take up, it gradually became invisible below, and as it went away over that field. The course of the general wind then blowing along with us as we travelled; and the progressive motion of the whirlwind was in a direction nearly opposite, though it did not keep a straight line; nor was its progressive motion uniform, it making little sallies as it went on either side, proceeding sometimes faster and sometimes slower, and seeming sometimes, for a few seconds stationary; then the other forwards pretty fast again. When we rejoined the company again, they were admiring the vast height of the leaves now brought by the common wind over our heads. These leaves as we travelled, falling now and then round about us, and some not reaching the ground till we had gone near three miles from the place where we saw the whirlwind begin.

WHISPERING-PLACES depend upon this principle: If the vibrations of the tremulous body are propagated through a long tube, they will be continually reverberated from the sides of the tube into its axis, and by that means from spreading, till they get out of it; whereby they will be exceedingly increased, and the sound rendered much louder than it would otherwise be. See Soudria.

Hence it is, that sound is conveyed from one side of a whispering-gellery to the opposite one, without being perceived by those who stand in the middle. The form of a whispering-gellery is that of a segment of a sphere, or a segment of a cylinder.

WHILST, a well-known name at cards, which requires great attention and silence; hence the name. This game is played by four persons, who cut for partners; the two highest and the two lowest are together, and the partners sit opposite to each other; the person who cuts the lowest card is to deal first, strong against none of the other persons, till he comes to the last card, which is turned up for the trump, and remains on the table till each person has played a card. The person on the left-hand side of the dealer plays first, and whoever wins the trick is to play again, the figures going on till all the cards are played out. The ace, king, queen, and knave, of trumps, are called honours; in case any three of these honours have been played between, or by either of the two partners, they reck on for two points towards the game; and if the four honours have been played between or by either of the two partners, they reckon for four points towards the game, the game consisting of ten points. The honours are reckoned after the tricks; all above six tricks reckoning also towards the game.

In Hoyle's Games may be seen the general rules for playing whist, which are too long for insertion here.

WHITING. See GADUS.

WICKLIFFISTS, or WICKLIFFITES, a religious sect which sprung up in England in the reign of Edward III. and took its name from John Wickliff, doctor and professor of divinity in the university of Oxford, who in six principal treatises made the sacramental bread and wine remained unaltered after consecration; and opposed the doctrine of purgatory, indulgences, auricular confession, the invocation of saints, and the worship of images. He maintained that children may be saved without being baptised; that priests may administer confirmation; that there ought to be only two orders in the church, that of priests, and that of deacons. He made an English version of the Bible, and composed two volumes, called Alethia, that is, Truth, from which John Husse learned most of his doctrines. In short, to this reformation we owe the first hint of the reformation which was effected about two hundred years after.

WIDOW, a woman who has lost her husband by death. In London, and throughout the province of York, the widow of a freeman is by custom entitled to her apparel, and the furniture of the bed-chamber, called the widow's chamber.

WIFE. After marriage, all the will of the wife, in judgment of law, is subject to the will of the husband, and it is commonly said a feme covert has no will. See Husband and Wife.

WILDERENCE, in gardening, a kind of grove of large trees, in a spacious garden, in which the walks are commonly made either to intersect each other in angles, or have the appearance of meanders and labyrinths.

Wilderness, says Mr. Miller, should always be proportioned to the extent of the gardens in which they are made; for it is very ridiculous to see a large wilderness planted with tall trees in a small spot of ground; and, on the other hand, nothing can be more absurd, than to see little paltry squares, or quarters of wilderness-work, in a magnificent large garden. As to the situation of wildernesses, they should never be placed too near one another, or so as to obstruct any distant prospect of the country, there being nothing so agreeable as an unconfined prospect; but where, from the situation of the place, the sight is confined within the limits of the garden, or there is any thing unsightly to be concealed, nothing can so well answer the purpose, as a well-designed scene of the various kinds of trees judiciously planted; and if it is so contrived, that the termination is planted circularly, with the concave towards the sight, it will have a much better effect, than if it ends in straight lines or angles. The plants should always be adapted to the size of the plantation; for it is very absurd for tall trees to be planted in the small squares of a little garden; and in large designs small shrubs will have a mean appearance.

As to the walks, those that have the appearance of meanders, where the eye cannot discover more than twenty or thirty yards in length, are generally preferable to all others, and these should now and then lead into an open circular piece of grass; in the centre of which may be placed either an obelisk, statue, or fountain; and, if in the middle of the wilderness there is contrived a large opening, in the centre of which may be erected a dome or banqueting-house, surrounded with a green plot of grass, it will be a considerable addition to the beauty of the whole. From the sides of the walks and openings the view should gradually rise above another above to the middle of the quarters, where should always be planted the largest-growing trees, so that the heads of all the trees may appear to view, while their stems will be hid from sight. Thus those parts which are planted with deciduous trees, roses, honey-suckles, spiras, and other kinds of low-flowering shrubs, may be planted next the walks and openings, and at their feet, near the sides of the walks, with primroses, violets, daffodils, &c., not in a straight line, but so as to appear accidental, as in a natural wood. Behind the first row of shrubs should be planted syringas, bilberries, meadowsweet, and other flowering shrubs of a middle growth; and these may be backed with many other sorts of trees, rising gradually to the middle of the quarters. The plant with evergreens may be disposed in the following manner; the first line next the great walks, may be placed the laevispinus, box, spurge-laurel, jujuber, savin, and other dwarf evergreens. Behind these may be placed larches, box, yews, cypresses, Virginia cedar, and other trees of the same growth; behind these may be planted Norway and silver firs, the true pine, and other sorts of the fir growth; and in the middle should be planted Scotch pines, pinaster, and other of the larger-growing evergreens, which will afford a most delightful prospect, if the different shades of the greens are curiously intermixed.

But beside the grand walks and openings, there should be some smaller walks through the middle of the quarters, where persons may retire for privacy; and by the sides of these private walks may also be scattered some wood flowers and plants, which, if artfully planted, will have a very good effect.

In the general design for these wilderesses, there should be an intermitting correspondence between the several parts; for the greater diversity there is in the distribution of these, the more pleasure they will afford.
WILL AND TESTAMENT, in law. Every person capable of binding himself by contract, is capable of making a will.

Also in the event of a male of 14 years and upwards, and female of 12 years and upwards, are capable of making a will respecting personal estates only.

But a married woman cannot make a will unless her spouse is reserved in her marriage settlement; but wherever personal property, however, is given to a married woman for her sole and separate use, she may dispose of it by will.

If a female sole makes her will, and afterwards marries, such marriage is a legal revocation of the will.

Wills are of two kinds, written and verbal; the former are most usual and secure. It is not absolutely necessary that a will should be witnessed; and a testament of chattels, written in the testator's own hand, though it should have neither the testator's name nor seal to it, nor witnesses present at his publication, will be good, provided sufficient circumstances can be had that it is his handwriting.

Gilb. 260.

By stat. 29 Car. II. c. 3, all devises of lands, and tenements, shall not only be in writing, but shall also be signed by the party so devising the same, or by some other person in his presence, and by his express direction, and shall be witnessed and subscribed in the presence of the person devising, by three or four credible witnesses, or else the devise will be entirely void, and the land will descend to the heir at law.

A will, even if made beyond sea, bequeathing land in England, must be attested by three witnesses. 2 P. Wms. 293.

A will, however, devising copyhold land, does not require to be witnessed; it is sufficient to declare the uses of a surrender of such copyhold land made to the use of the will. The party to whom the land is given becomes entitled to it by means of the surrender, and not by the will. 2 Atk. 37.

A codicil is a supplement to a will, or an addition made by the person making the same, annexed to, and to be taken as part of, the will, with the intention, by way of correction, to add something to, or take something from, the former disposition, and which may also be either written or verbal, under the same restrictions as regard wills.

If two wills are found, and it does not appear which was the former or latter, both will be void; but if two codicils are found, and it cannot be ascertained which was the first, but the same thing is devised to two persons, both ought to divide; but where either wills or codicils have dates, the latter is considered as valid, and revokes the former. See Administrator, Executor, and Legacy.

WILL WITH A WISP, or Jack with a lantern. See Meteor.

WILLICHA, a genus of plants of the common order triandria monogyne. The calyx is four-leaf; corolla ditto; capsule two-celled, many-seeded. There is one species, an annual of Mexico.

WILLUGHBEIA, a genus of plants of the common order triandria monogyne. The corolla is salver-shaped; stigma headed; fruit one or two celled, berry or pumpkin. There are two species, trees of Guiana.

WIND, a sensible current in the atmosphere. The motions of the atmosphere are subject, in a certain degree, to the same laws as those of water. If we remove a portion of the water in a large reservoir, we see the surrounding water flow in to restore the equilibrium. If we impel, in any direction, a certain portion, an equal quantity will move in a contrary direction from the same cause. If a portion, being rarified by heat, or condensed by cold, ascends or descends, a counter-current in another part is the necessary and certain result. It is thus in the atmosphere. No wind can blow without a counter-current in an opposite direction; or arise without a previous destruction of the equilibrium, the general causes of which are:

1. The ascent of the air over certain tracts.
2. Evaporation causing an actual increase in the volume of the atmosphere. 3. Rain, &c., causing an actual decrease in volume by the destruction of the vapour.

Currents thus produced remain general, extending over a large portion of the globe; periodical as in the Indian ocean; or variable, and as it were occasional, or at least uncertain, as the winds in temperate climates. General, permanent winds blow always nearly in the same direction. In the Atlantic and Pacific oceans, under the equator, the wind is almost always easterly; it blows, indeed, in this direction, on both sides of the equatorial line, at the latitude of 20°. More to the northward of the equator, the wind generally blows between the north and east; and the farther north we proceed, we find the wind to blow to a northwestern direction; more to the southward of the equator it blows between the south and east; and the farther towards the south, the more it comes in that direction.

Between the parallels of 28° and 40° south lat, in that tract which extends from 30° west to 100° east longitude from London, the wind is variable, but it most frequently blows from between the N. W. and S. W. so that the outward-bound East India ships generally run down their easting on the parallel of 30° south.

Navigators have given the appellation of trade-winds to these general winds.

Periodical winds. Those winds, which blow in a certain direction for a time, and at certain stated seasons change and blow for an equal space of time from the opposite point of the compass, are called monsoons. During the months of April, May, June, July, August, and September, the wind blows from the southward over the whole length of the Indian ocean, viz. between the parallels of 28° N. and 28° S. lat. and between the eastern coast of Africa and the meridian which passes through the western part of Japan; but in the other months, October, November, December, January, February, and March, the winds in all the northern parts of the Indian ocean shift round, and blow directly contrary to the course they held in the former six months. For some days before and after the change, there are calms, variable winds, and tremendous storms, with thunder, &c.

Philosophers differ in their opinions respecting the natural trade-winds; but a more probable theory of the general trade-winds is, that they are occasioned by the heat of the sun in the regions about the equator, where the air is heated to a greater degree, and consequently rarefied more than, in the more northern parts of the globe. From this expansion of the air in the tropical regions, the denser air, in higher latitudes, rushes violently towards the equator from both sides by this confluence. And in the denser air, without any other circumstances intervening, a direct northerly wind would be produced in the northern tropic, and a southern one in the other tropic; but as the earth’s rotational motion varies the direct influence of the sun on the surface of the earth, and as by that motion this influence is communicated from east to west, an easterly wind would be produced if this influence alone prevailed. On account of the cooperation of these two causes at the same time, the trade-winds blow naturally from the N. E. on the north, and from the S. E. on the south of the line, throughout the whole year; but as the sun approaches nearer to the tropics in the summer season, the point towards which these winds are directed will not be invariably the same; but they will incline more towards the north in that season, and more towards the south in our winter. The land and sea breezes in the tropical climates may be considered as partial inter- ruptions of the general trade-winds; and the cause of these is not very difficult to explain. From the heat of the earth, the water is always of a more even temperature. During the day, therefore, the land becomes considerably heated, the air rarified, and consequently in the afternoon to the west of the sea, which is less heated at that time than the land. On the other hand, during the night the earth loses its surplus heat, while the sea continues more even in its temperature. Towards morning, therefore, a breeze regularly proceeds from the land towards the ocean, where the air is warmer, and consequently more rarefied, than on shore.

The cause of the monsoons is not so well understood as that of the general trade-winds, which has been just remarked, suggests, at least, a probable theory on the subject. It is well known, that at the equator the changes of heat and cold are occasioned by the diurnal variation of the sun, and that the difference of heat between the day and the night is almost all that is perceived in those tropical regions; whereas in the polar regions the great vorticities of heat and cold are occasioned by the continual motion of the globe, which produces the sensible changes of winter and summer; consequently, if the heat of the sun was the only cause of the variation of the winds, the changes, if any, that would be produced by these means in equatorial regions, ought to be diurnal only, but the changes about the pole should be experienced only once in six months. As the effects arising from the heat of the sun upon the atmosphere cannot be greater at the equator than at the poles, the changes of the wind arising from the expansion of the air by the sun’s rays must be more steady in equatorial than in polar regions. The incontrovertible evidence of this truth, that the winds are more variable towards the pole, and more constant towards the equator. But in summer, the continual heat, even in high latitudes, comes to be sensibly felt, and produces changes on the wind, which are distinctly perceptible. In our own cold region
the effects of the sun on the wind are felt during the summer months; for while the weather in that season of the year is fine, the wind generally becomes stronger as the time of the day advances, and dies away towards the evening, and assumes that pleasing serenity so characteristic of India. But in winter, and at the different quarters of the year, the diurnal changes of the wind in northern climates. The annual revolution of the sun produces still more sensible effects. The prevalence of the western winds during summer may contribute to this cause, which is still more perceptible in France and Spain; because the continent of land to the eastward, being heated more than the waters of the Atlantic ocean, the air is drawn, during that season, towards the east, and consequently produces a western wind.

But these effects are much more perceptible in countries near the tropics than with us. For when the sun approaches the tropics of Cancer, the soil of Peria, Bengal, China, and the adjoining countries, becomes much more heated than the sea to the southward of those countries, that the current of the general trade-wind is interrupted, so as to blow from the south to the north, contrary to what it would do if no land was there. But as the high mountains of Africa, during all the year, are extremely cold, the low countries of India, to the eastward of it, become better than Africa in summer, and the air is naturally drawn thence to the eastward. From the same cause it follows, that the trade-wind in the Indian ocean, from April till October, blows in a northeast direction; but the trade-wind in open seas in the same latitude; but when the sun retires towards the tropic of Capricorn, these northern parts become colder, and the general trade-wind assumes its natural direction.

Having given the most obvious causes of the periodical monsoons in the Indian seas, it is necessary to observe, that no monsoon takes place to the southward of the equator, except the ocean around New Holland. There the same causes concur to produce a monsoon as in the northern tropic, and similar appearances take place. From October till April the monsoon sets in from the opposite side of the globe; the general course of the trade-wind on the other side of the Line; and here also the general trade-wind resumes its usual course during the other months, which constitute the winter season in these regions. It may not be improper to conclude this account of the tropical winds, by enumerating some of the principal influences of the monsoons.

Between the months of April and October, the winds blow from the S.W. wind all that part of the Indian ocean which lies between Madagascar and Cape Comorin, and in the contrary direction from October to April, with some small variation in different places; but in the bay of Bengal these winds are neither so strong nor so constant as in the Indian ocean. It must also be remarked, that the S.W. winds in those seas are more southerly on the African side, and more westerly towards India; and the variations are not so great as to be repugnant to the general theory. The cause of this variation is, as was before intimated, that the mountainous lands of Africa are colder than the flatter regions of Arabia and India; consequently the wind naturally blows from those cold mountains in the summer season, towards the warmer lands of Asia, which occasions those inflations of the wind to the eastward during the summer months. The peninsula of India, lying so much farther to the north than Arabia and Persia, adds greatly to this effect; because the wind naturally draws towards them, and produces that easterly variation of the monsoon which takes place in this part of the ocean, while the sandy deserts of Arabia draw the winds more directly northward, near the African coast. A similar chain of reasoning will serve to explain any other inflations or variations that may occur in the perusal of books of travels.

WINDS, variable. In the temperate zones the direction of the winds is by no means so regular as between the tropics. Even in the same degree of latitude we find them often blowing in different directions at the same time; while their changes are frequently so sudden and so capricious, that to account for them is hitherto been found impossible. When winds are violent, and continue long, they generally extend over a large space of land or sea, and affect the climate of regions at a distance. The case is more certainly the case when they blow from the north or east than from any other points. By the multiplication and comparison of meteorological tables, some regular connection between the changes of the atmosphere in different places may in time be observed, which will at last lead to a satisfactory theory of the winds. It is from such tables chiefly, that the following facts have been collected:

In Virginia, the prevailing winds are between the south-west, west, north, and north-west; the most frequent is the south-west, which blows more constantly in June, July, and August, than at any other season. The north-west winds blow most constantly in the month of December, January, and February, they blow from the north, north-west, and west; towards the end of February they change to the south, in which quarter they continue till near the end of March; during the last days in March and in April, they blow from the south-west, and at last from the east; and in this direction they continue during a part of May.

In the Mediterranean the wind blows nearly three-fourths of the year from the north; but there is always an easterly wind in that sea, which is generally more constant in spring than in summer. These observations do not apply to the gut of Gibraltar, where there are seldom any winds except the east and the west.

At Brest, in the island of Cornica, the prevailing wind is the south-west.

In Syria the north wind blows from the autumnal equinox to November; during December, January, and February, the winds which blow from the north-west, they blow from the north, in May from the east, and in June from the north. From this month to the autumnal equinox, the wind changes gradually as the sun approaches the equator, and continues blowing south and west, and at last to the east. At Bagdad, the most frequent winds are the south-west and north-west; at Pekin, the north and the south; at Kamtschatka, on the north-east coast of Asia, the prevailing winds blow from the north.

In Italy, the prevailing winds differ considerably according to the situation of the places where the observations have been made: at Rome and Padua, they are northerly, at Milan easterly. All that we have been able to learn concerning Spain and Portugal is, that on the west coast of these countries, the west is by far the most common wind, particularly in summer; and that at Madrid the wind is north-east for the greatest part of the summer, blowing almost constantly from the Pyrenean mountains. At Berne in Switzerland, the prevailing winds are the north and west; at St. Gothard, the north-east; at Lausanne, the north-west and south.

Father Cotte has given us the result of observations made at 86 different places of France; from which it appears, that along the whole south coast of that kingdom the wind blows most frequently from the north, north-west and north-east; on the west coast, from the west, south-west, and north-west; and on the north coast from the south-west. That in the interior parts of France, the south-west wind blows most frequently in 18 places; the west wind in 14; the north in 13; the south in 6; the north-east in 4; the south-east in 2; the east and north-west each of them one. On the west coast of the Netherlands, as far as Rotterdam, the prevailing winds are probably the south-west, at least this is the case at Dunkirk and Rotterdam. It is probable also, that along the rest of this coast, from the Hague to Hamburgh, the prevailing winds are the north-west, at least these winds are most frequently the case on the Hague and at Franeker. The prevailing wind at Delt is the south-east; and at Breda, the north and the east.

In Germany, the east wind is most frequent at Gottingen, Munich, Weimar, Nuremberg, Dresden, Sigmund, Erford, and at Buda.

Mean: 220.3 144.7

In Ireland, the south-west and west are the grand trade-winds; blowing most in summer, autumn, and winter, and least in spring. The north-east blows most in spring, and nearly double to what it does in autumn and winter. The south-east and north-west are nearly equal, and are most frequent after the south-west and west.

At Copenhagen the prevailing winds are the east and south-east; at Stockholm, the west and north. In Russia, from an average of a register of 16 years, the winds blow from November to April in the following order:

W. N. W. E. S. W. S. N. E. S.
Days 43 26 33 22 29 19 14 12

And during the other six months,

W. N. W. E. S. W. S. N. E. S.
Days 27 27 19 24 22 15 32 18

The west wind blows during the whole year 72 days; the north-west 58; the south-west and north 46 days each. During summer it is calm for 41 days, and during winter for 21. In Norway, the most frequent winds are the south, the south-west, and south-east. The wind at Bergen is seldom directly west, but generally south-west, or south-east; a north-west, and especially a north-east wind, are but little known there.

From the whole of these facts, it appears that the most frequent winds on the coast of Europe are the north-east, north-west, and north-west and north-east; and on the western coast, the south-west: that in the interior parts which lie most contiguous to the Atlantic ocean, south-west winds are also most frequent; but that easterly winds prevail in Germany. Westerly winds are also most frequent on the north-east coast of Asia.

It is probable that the winds are more constant in the south temperate zone, which is in a great measure covered with water, than in the north temperate zone, where their direction must be frequently interrupted and altered by mountains and other causes.

M. De la Caille, who was sent thither by the French king to make astronomical observations, informs us, that at the Cape of Good Hope the main winds are the south-east and north-west; that other winds seldom last longer than a few days; and that the east and north-east winds blow very seldom. The south-east wind blows in most months of the year, but chiefly from October to April; the north-west prevails during the other six months, bringing along with it rain, and tempests. Between the Cape of Good Hope and New Holland, the winds are commonly westerly, and blow in the following order: north-west, south-west, west, north.

In the Great South Sea, from latitude 30° to 40° south, the south-east trade-wind blows most frequently, especially when the sun approaches the tropic of Capricorn; the wind next to it in frequency is the north-west, and next to that is the south-west. From south latitude 40° to 50°, the prevailing wind is the north-west, and next the south-west. From south latitude 50° to 60°, the most frequent wind is also the north-west, and next to it is the west.

Thus it appears that the trade-winds sometimes extend farther into the south temperate zone than their usual limits, particularly during summer; that beyond their influence the winds are commonly westerly, and that they blow in the following order: north-west, south-west, west.

Such is the present state of the history of the direction of the winds. In the torrid zone they blow constantly from the north-east on the north side of the equator, and from the south-east on the south side of it. In the temperate zones they blow most frequently from the south-west; in the south temperate zone from the north-west, changing, however, frequently to all points of the compass; and in the north temperate zone blowing particularly during spring, from the north-east.

As to the velocity of the wind, its variations are almost infinite; from the gentlest breeze, to the hurricane which tears up trees and blows down houses. It has been remarked, that our most violent winds take place when neither the heat nor the cold is greatest; that violent winds generally extend over a great tract of country, and that they are accompanied by sudden and great falls in the mercury of the barometer. The reason appears to be, that violent winds succeed the precipitation in rain of a large quantity of vapour, which previously constituted a part of the bulk of the atmosphere; and this precipitation cannot take place when the general temperature approaches to either extreme. The wind is sometimes very violent at a distance from the earth, while it is quite calm at its surface. On one occasion Lamarti went at the rate of 70 miles an hour, in his balloon, though it was quite calm at Edinburgh when he ascended, and continued so during his whole voyage. The same thing happened lately to Garnier and his companion in their aerostatic voyage to Colchester. This again may be illustrated by the motions of dense fluids, which are always impeded in the parts contiguous to the sides and bottom of the vessels; and the same thing happens in tide-rivers, where the boatman, when he wishes to proceed with the tide, commits himself to the middle of the stream: but when he has to strive against it, he keeps close to the shore. It is, therefore, not the upper parts of the atmosphere which are accelerated, but the lower are retarded by friction against the surface of the earth.

The following table, drawn up by Mr. Smouton, will give the reader a pretty precise idea of the velocity of the wind in different circumstances:
WINDMILL, a kind of mill, the internal parts of which are much the same with those of a water-mill; from which, however, it differs in the absence of a water-wheel and the absence of a stroke of the wind upon its vanes, or sails, which are to be considered as a wheel on the axle.

There are various kinds of windmills. We shall content ourselves with describing the horizontal windmill, the construction of which is not so generally known as that of the others.

Plate Windmill, represents a horizontal windmill erected about 50 years ago at a distillery near Battersea, for grinding malt and corn. AA (fig. 1) is the main shaft, which turns on a gudgeon working in so as to be guided by solid masonry; this shaft has several wheels, as BB, attached to its upper part, as shown in fig. 2, for carrying a great number of float-boards DD, similar to a water-wheel, except being a little conical. This wheel is included in a frame EE, composed of several circular rings, connected by upright timbers, and strengthened by transverse braces, and which has timbers across the top to support the upper part. The wheels are set by a shaft AA, supported by a socket in the frame EE, and the ends, as shown at FF, the boards turn on a centre at the edge nearest the wheel, so that they can be set open, as in fig. 2, or be shut up so as to touch one another, and to allow no air to pass between them.

When the boards FF are set, as in fig. 2, it will be evident, from inspecting the figure, that the wind blow in any direction, it will always enter the building on one side, the other being in such a position that the wind cannot enter, and striking on the floats of the wheel will turn it round. The quantity of wind which strikes the wheel can be regulated by closing or opening the boards FF, all at once, which is done by a contrivance, shown in fig. 3. IIIH represents a plan of a part of the circular sail at the bottom of the frame EE, (figs. 1 and 2); IF are the wind-boards, which move on a centre at the edge of the sail; the boards have levers, GG, nailed to their lower ends, by which they can be turned about on the centre; II are rods, joined to the levers GG, the other ends of which are joined to a circular ring, of which KK is a segment; this ring rests upon rollers fixed in the floor beneath the sails.

When this ring is turned round one way, the rods II push the ends of the levers GG, and close up the boards; on the contrary, when it is turned the other way, it opens them.

The ring K has at one part of its under side a short cast iron segment with cope, which work in a corresponding one fixed to the floor. The axis of this pinion goes through the mill and into the open air, and is connected by ropes with a handle below the ground-floor of the mill.

When the miller turns this handle, it also turns the ring K (fig. 3), and, as before described, opens or closes the boards FF, and regulates the mill's velocity.

The main shaft, AA, has a large cog-wheel, O, fixed upon it, which turns two trundles on the shafts LM, on which the wheels NN are also fixed: each of these wheels turns three pinions, only one of which is represented on the axis of the mill-stones, which are arranged round the wheels NN, at proper intervals, like those described under the article FLOUR-MILL. The shaft LL has a beveled wheel at its upper end, which turns another, m, on the shaft u; which has riggers, as P, fixed on it, and by means of straps turns the bolting-mills; for a description of which see FLOUR-MILL.

With regard to the common windmills, we must observe that a patent has lately been taken out by Mr. Sutton, of Battersea, for a circular contrivance, entitled "A Sketch of the Properties and Advantages of Sutton's Patent Gravitated Sails for Windmills." We refer the reader to the article WIND-SAILS, for a full account of these, we can with pleasure refer to a work entitled "A Sketch of the Properties and Advantages of Sutton's Patent Gravitated Sails for Windmills," by W. S. Hefleden.

WIND-SAILS, in a ship, are made of the common sail-cloth, and are usually between 25 and 30 feet long, according to the size of the ship, and are of the form of a cone when upright. When they are made use of, they are hoisted by ropes to about two-thirds or more of their height, with their basis directed circularly by hoops, and their apex hanging downwards in the hatchways of the ship; above each of these, one of the common parts of the air rushing against it is directed into the wind-sail, and conveyed, as through a funnel, into the upper parts of the body of the ship.

Two-Ton-knife, a windlass, in a ship, are the main double blocks, which, being made fast to the end of a small cable, serve for hoisting goods into the ship, &c.

To WIND, or WEND, a ship, signifies to bring her head about. How wind or winds a ship is a question asked by mariners concerning a ship under sail; signifying as much as, upon what point of the compass does she lie with her head.

WINDWARD, in the sea language, denotes any thing towards that point from which the wind blows in respect of a ship: thus windward is the tide which runs against the wind.

Large Wind. In the sea language, to sail with a large wind, is the same as with a fair wind.

WINDAGE of a gun, mortar, or howitzer. The difference between the diameter of the bore, and the diameter of the barrel or shell.

In England, the great number of the shot supposed to be divided into 20 equal parts, and the diameter of the bore into 21 of those parts. The French divide the shot into 20, and the bore into 27. The Prussians divide the shot into 24, and the bore into 29. The Dutch nearly the same as the English. The general windage of shells in England is a quarter of an inch, let them be large or small, which is contrary to all reason. It is evident, that the less windage a shot or shot should have and true it will go; and having less room to bonsie from side to side, the gun will not be spoiled soon.

It is true that some artillery-officers say, that the windage of a gun should be equal to the thickness of the blade; because, when it has been loaded for a while, the shot will not come out without being loosened thereby, in order to unload it; and when this cannot be done, it must be fixed away, and so lost, but the most advantageous windage would be in dividing the shot in 24 equal parts, and the bore into 23, on account of the convenient scale it affords, not only to construct guns by, but also their carriages. Hence, according to this plan, the windage of a 9-pounder will be 160 of an inch, consequently a sufficient thickness for a blade; and those of a higher calibre become still thicker in proportion; but suppose this thickness is not enough, then, it is a mere trifle, in respect to the advantage otherwise gained.

WINDING STAIRS. See STAIRS.

WINDLASS, or Windlass, a machine used to raise large weights, as guns, stones, &c. See MECHANICS.

WINDLASS, in a ship, is a instrument, in small ships placed upon the deck, just about the foremost. It is made of a piece of timber six or eight feet square, in form of a tree, whose length is placed horizontally upon two pieces of wood at the ends, and upon which it is turned about by the help of handspikes put into holes made for that purpose. This instrument serves for raising goods, or hoisting of any weight in or out of the ship, and will purchase much more than any capstan, and that without any danger to those who have; for if in heaving the windlass about, any of the handspikes should happen to break, the windlass would fall of itself.

WINDOW. See ARCHITECTURE.

WINES. It is known that 10 substances, except such as contain the saccharine principle, except the granulated fermentation, and that in order to be susceptible of it, these saccharine substances must always contain a certain portion of extractive matter; for Lavosier has proved, that sugar cannot ferment, unless there be something obliged to add it to it a quantity of yeast in order to make it undergo this change.

The principles of which yeast consists are oxygen, hydrogen, carbon, and azote. The process of fermentation decomposes them, and gives rise to new products, namely: Water, carbonic acid, alcohol, acetous acid, saccharine residuum, and a residuum of the yeast.

The effects of the vinous fermentation consist, therefore, in separating the sugar, which is an oxide, into two parts; in oxygenating the one, at the expense of the other, to form carbonic acid; in deoxygenating the other in favor of the first, to form a combustible substance termed alcohol; so that was it possible to combine the two substances, the alcohol and the carbonic acid, one might reproduce sugar. It is necessary to remark, that the hydrogen of sugar does not exist in the state of oil in alcohol, being combined with a portion of oxygen, which
renders them miscible with water. These three principles, therefore, the oxygen, the hydrogen, and the carbon, are here in a kind of equilibrium; and, in fact, by making them pass through a red-hot tube of glass or porcelain, we may re-combine them two and two together, and the product will be water, hydrogen, carbonic acid, and carbon.

The analysis of wine commences in the cask, after which it successively deposits tar, lees, and its colouring principle, till at length hardly any thing remains besides alcohol and a small quantity of extractive matter, dissolved in a proportion of water more or less abundant. But this accurate analysis, which exhibits to us the principles of wines in their separate states, throws very little light upon their real nature, a deficiency which we shall endeavour to supply by a more rigorous method of investigation.

We shall distinguish in all wines an acid, alcohol, tartar, an extractive matter, aroma, and a colouring principle; the whole being diluted or dissolved in a smaller or larger proportion of water.

1. The acid. An acid exists in all wines; and we have never met with any in which we could not discover some traces of its presence, as well as the most watery wines, impart a red tinge to blue paper that is kept for some time immersed in them; but all wines are not acid in the same degree. Some wines, a natural acidity is the principal characteristic; those produced from grapes not perfectly ripe, or that grow in most climates, are of this kind; whilst such as are the product of the fermentation of grapes that have attained complete maturity and sweetness, contain but a very small quantity of acid. The proportion of acid appears, therefore, to be in the inverse ratio of the saccharine principle, and consequently of the alcohol, which is produced by the decomposition of the sugar.

This acid exists in great abundance in verjus; it is also found in must, though in less quantity. All fermented liquors, such as cider, perry, beer, and fermented farinaceous substances, contain this acid in a greater or less manner. It is even found in melasses. Indeed, it is only for the purpose of completely saturation it, that fins, ashes, and other earthy or alkaline bases, are used in refining sugar; otherwise the very presence of the acid would impede the crystallization of this salt.

If we concentrate wine by distillation, the extract which remains is in general of a sour pungent taste. Water, or even alcohol, poured upon this extract, will be sufficient to dissolve and raise the acid. This acid has a slightly empyreumatic smell, leaves a bitterish taste in the mouth, &c.

This acid, well filtered and left to stand in a flask, deposits a considerable quantity of extractive matter; it afterwards becomes covered with mould, and seems to approach to the nature of the acetic acid; by distillation it may be purified of a great quantity of the extractive matter, after which it becomes less liable to be decomposed by the putrefactive fermentation.

This acid precipitates the carbonic acid in its combinations; it dissolves most of the metallic salts with facility; forms the insoluble salts with lead, silver, and mercury; and separates the metals from all their solutions by acids.

This acid forms also an insoluble salt with lime. When we mix a large quantity of lime-water with wine, the acid is precipitated from it, and carries with it the whole of the colorizing principle.

This acid, therefore, is of the nature of the malic acid; it is always mixed with a small proportion of nitric acid; for, if it is digested upon the oxide of lead, besides the insoluble precipitate that is formed, a citrate is always produced which can be demonstrated by the known methods.

This malic acid disappears when the wine is converted into vinegar; it no more exists in well-prepared vinegar than it does in the acetic acid. This transformation of the malic acid into acetic acid, affords a natural explanation why that wine which has begun to sour cannot be employed in the preparation of the acetic of bread; in this case an insoluble precipitate is produced.

The existence, in different proportions, of the malic acid in wine, enables us to account for a phenomenon of the utmost importance, relative to the distillation of wines, and the properties of the vinous spirits which result from this process. Every one knows, not only the best but the worst of wine, the proportion of spirit, but likewise that the distilled spirits produced from different kinds of wine differ very widely from each other in their quantities. It is also well known that wines of a sour, pungent, and fermented farinaceous substances, yield but a small quantity of spirit, and that always of a bad quality. Careful and repeated distillations may indeed correct these faults to a certain degree, but they can never take them away altogether. These constant results, from a long course of experience, have been attributed to the superabundance of the extractive matter contained in these weak spirituous liquors; the composition of a portion of this matter, by distillation, seemed to be the immediate consequence, and the acid empyreumatic taste its natural effect. But, upon a more accurate investigation of this phenomenon, it is found that, besides the cause which is operated upon the superabundance of the extractive principle, another ought to be attended to, namely, the presence of the malic acid in almost all these cases.

Those wines which contain the largest proportion of malic acid, afford the worst-conditioned spirit. It appears even that the quantity of alcohol is less in proportion as that of the acid is more considerable. If we separate this acid by means of lime-water, lime, chalk, or some fixed alkali, we can only draw off a very small quantity of alcohol by distillation; and, in every case, the spirit acquires a very sour pungent taste, which does not tend to meliorate its quality.

The difference of the spirits obtained by distillation from different wines, depends, therefore, principally upon the different proportions in which these wines contain malic acid; but no process has been hitherto discovered by which we can with certainty destroy the bad effects which the admixture of this acid with vinous spirits produces.

This acid, which we find in the grape at the utmost period for which they appear in wines till they have completely degenerated into vinegar, ought in preference to be denominated the vinous acid; however, for the sake of avoiding confusion, we shall retain the usual term of malic acid.

2. Alcohol. Alcohol forms the true characteristic of wine. It is the product of the decomposition of sugar, and its quantity is always proportionate to that of the sugar that has been decomposed.

Alcohol abounds more in some wines than it does in others; those of hot climates contain a large quantity of it, whilst those of cold climates contain scarcely any. Ripe and sweet grapes produce it in abundance; but the wines made of grapes that are unripe, watery, and sour, yield very little.

Some wines produced in the southern parts of our hemisphere, yield alcohol in the proportion of one-third of their quantity; whilst many of those manufactured in more northern latitudes contain not more than one-fifteenth. It is the proportion of alcohol contained in them that renders wines more or less generous; and upon the same circumstance depends their disposition or resistance to the acetic fermentation. The less a wine contains of alcohol it turns sour; the proportion of extractive matter contained in it being supposed the same in both cases.

The richer in spirit a wine is, the less it contains of malic acid; and this is the reason why the best wines, in general, furnish the best brandies; as they are then exempt from the presence of this acid, which gives them a disagreeable flavour.

It is by distillation that we extract from wines the whole of the alcohol they contain.

When wines are distilled, the operation is carried on till the liquor which passes over is no longer inflammable.

Wines furnish more or less brandy in proportion to their different degrees of spirituosity. A very generous wine furnishes about a third of its weight: the mean proportion of the brandy, furnished by the wines of the southern provinces of France, is about one-fourth of the whole; some even yield as much as one-third.

Old wines yield better brandy than new ones, but in less quantity, particularly when the decomposition of the saccharine principle has been completely accomplished and subjected to the process of distillation.

That which remains in the boiler, after the brandy has been extracted, is called vinasse; and is a confused mixture of tartar, malic acid, &c. This residuum is generally thrown away as useless; nevertheless, after drying it in the air, or by means of a stove, a tolerably pure alkali may be extracted from it by combustion.

In some distilleries the vinasse is suffered to turn sour, in order afterwards to distill, and extract the small quantity of vinegar that has been formed in it.

Brandy is the more spirituous in proportion as it is mixed with a smaller proportion of water; and as it is of importance in commerce, that we should be able easily to ascertain the degrees of spirituosity, attention is being paid to the means by which this may be performed.

The distiller judges of the spirituosity of brandy by the number, the magnitude, and the permanency, of the bubbles which form themselves upon agitating the liquor. With this view it is customary to pour the vessel into another, or suffered to fall from a certain height, or, which is the more general practice,
WINE.

It is inclosed in an oblong flask, as to fill about two-thirds of the whole, and violently agitated, the mouth of the flask being kept tightly closed with a thickness of the thumb. This last apparatus is called the sound.

The test by combustion, in the manner it is usually practised, is very faulty. The regulation of the year 1799 directs to put gunpowder into a boiler, and, after covering with the lid, apply the pressure of the thumb. The burning must be of good quality if it sets fire to the powder, and bad in the contrary event.

But the same quantity of liquor either does, or does not, set fire to gunpowder, according to the method in which it is employed: a small proportion always does it, and a large one never; for, in the last case, the water contained in the liquid is sufficient to wet the powder, and prevent its taking fire.

Salt of tartar (carbonat of potash) is also employed as a test for brandy. This alkali is soluble in water, but not in alcohol; so that upon dissolving it in brandy, the alcohol swims at the top of the solution.

The defective nature of these processes has rendered it necessary to have recourse to means capable of determining the spirituosity of a liquor by ascertaining its specific gravity.

A drop of oil poured upon alcohol fixes itself upon the surface, or falls to the bottom, according to the degree of spirituousness which the liquor possesses. This method has been adopted and proposed by the Spanish government in the year 1770; but it is subject to inaccuracy, as the effect depends upon the height from which it falls, the weight of the oil, the proportion in which it is employed; and the temperature of the atmosphere, the dimensions of the vessel, &c.

In the year 1772, this important subject was resumed by two able philosophers, namely, Karie and Projet de Cetie, who introduced in Languedoc, an hydrometer, to which they adapted a thermometer, the different degrees of which constantly indicate the corrections requisite to be made in the graduation of the hydrometer, on account of the very variable temperature of the atmosphere. By the aid of this hydrometer, one may not only ascertain the degree of spirituousness, but also bring the brandy to any degree that may be thought necessary.

For this purpose different weights are used, the heaviest of which is marked Holland-proof, and the highest 3—7; so that if we see, at the lower extremity of the scale of the aræometer, Holland-proof, and plunge the instrument into a liquor 3—7, it sinks much too deep; but we may raise it again to the level of Holland-proof, by adding four-sevenths of water.

If, on the contrary, we have the weight 3—7, and plunge the aræometer into a liquor Holland-proof, it will rise in the liquor above this last term, to which it may easily be reduced by adding alcohol of a higher degree of spirituousness.

When brandies are to be distilled for the purpose of extracting their alcohol, the compound bath is usually employed. The heat is then more gentle and equal, and the product of the distillation of a better quality. This is what is called spirit of wine in commerce.

3. The tartar. Tartar exists in verjusce, as also in must; it contributes to facilitate the formation of alcohol, as we have already observed, according to the experiments of Baltis. It deposits itself upon the sides, forming a crust, more or less thick, with crystals of irregular forms. Some time before the vintage, when the casks are to be got ready for receiving the juice, they are stored away in tartar detached from them, in order to be employed in the different uses of commerce.

Tartar is not furnished in equal quantity by all wines; the red wines yield a larger proportion of it than the whites; those of the deepest colour and thickest consistence generally yield the most.

Its colour likewise varies very much; and it is distinguished into white and red tartar, according to the colour of the wines from which it has been deposited.

This salt has little solubility in cold water, but considerably more in boiling water. It scarcely dissolves at all in the mouth, and it resists the pressure of the teeth.

It is deprived of its colouring principle by a simple process, and it is then termed cream of tartar. For this purpose it is dissolved in boiling water, and as soon as the solution is saturated, it is put into a Earthen pot to cool.

In cooling, it deposits a layer of crystals, which are already very nearly deprived of their colour. These crystals are again dissolved in boiling water, and the solution mixed in the proportion of five parts to a hundred, with a sandy argillaceous earth, which is dug at Morveil, near Montpellier. This mixture is evaporated till a pellicle forms upon it; in cooling it deposits white crystals, which, after being exposed for some days to the air, upon cansa, acquire that whiteness by which cream of tartar is distinguished. The original water is preserved in order to be employed in new solutions.

Tartar is purified also by calcination. By this operation its acid is decomposed and destroyed, so that nothing remains besides the alkali and the carbon. The alkali is dissolved in water; and by filtering and evaporating the solution, we obtain the salt well known in pharmacy by the name of salt of tartar, or carbonat of potas.

Tartar furnishes not more than about a fourth part of its weight in crystals. The extractive principle. The extractive principle abounds in must, where it appears to be dissolved by the aid of the sugar: but when the saccharine principle is decomposed by means of fermentation, the quantity of extractive matter sensibly diminishes; a part of it deposits itself in a fibrous form; and this deposit, which principally constitutes the lees, is the more considerable in proportion as the fermentation is more gentle, and the alcohol more abundant. This deposit is always mixed with a considerable quantity of tartar.

There always exists in wine a proportion of extractive matter in a state of dissolution, which may be separated from it by means of evaporation. It abounds more in new wines than in old ones; and the older the wine grows, the more completely is it freed from the extractive principle.

The lees, after being well pressed, are dried in the sand, or in stoves, and then burnt, in order to extract that species of alkali known in commerce by the name of pearl-ashes. The resinum, after the combustion, is a porous mass, of a greenish-grey colour, and forms about a third part of the whole quantity of leaves that have been burnt.

5. The aroma. All natural wines have an odour more or less agreeable to the smell. Some of the latter owe it to volatile substances, either because it is conventions the strong smell of the alcohol, or because it has been destroyed or dissipated by the violent fermentation that was requisite to develop the spirit.

This aroma does not appear to be capable of being extracted and communicated to pleasure to other substances. Even heat seems to destroy it; for, excepting the first liquid that passes over in distillation, which still retains something of the odour peculiar to the wine, the brandy which follows after has only those properties that essentially belong to it.

6. The colouring principle. The colouring principle of wine belongs to the residue of the vegetable ferment, which is left unchanged in fermenting, except when it is kept in a state of ferment, without it, the wine is white. This colouring principle does not dissolve till the alcohol is developed; it is only then that the wine acquires its colour, which is deeper in proportion to the violence of the fermentation.

A portion of the colouring principle deposits itself in the cask, together with the tartar and the lees; and, as the wine grows old, it is not unfrequent to see it entirely lose its colour: the colouring principle then deposits itself in pellicles on the sides or bottom of the cask, and is seen floating in the liquid in the form of films, which injure its transparency.

If we expose bottles filled with wine to the rays of the sun, a few days are sufficient to precipitate the colouring principle in large pellicles; the wine losing neither its perfume nor its strength.

By adding a large quantity of lime-water to wine we precipitate its colouring principle. In this case the lime combines with the malic acid, and forms a salt which appears in light flakes in the liquid. These flakes gradually sink to the bottom, carrying with them the whole of the colouring principle. The deposit is black or white, according to the colour of the wine on which we operate. It frequently happens, that a wine is still susceptible of a new precipitation, although it had been completely discolorated by the first deposit, which proves that the colouring principle has a very strong affinity with the malate of lime. This coloured precipitate is not soluble either in cold or in hot water. Alcohol has scarcely any effect upon it, except that it acquires a slight brownish tinge. The nitric acid dissolves the colouring principle of this precipitate.

When wine is reduced to the state of extract, alcohol purified purifies it of a deep tinge, in the same manner as water does, though not in an equal degree. But, besides the colouring principle which then dissolves itself, there is also a saccharine extractive principle present, which facilitates the solution.
The colouring principle, therefore, does not appear to be of a resinous nature; it exhibits the characteristic of belonging to the numerous class of vegetable products, which approach to the nature of the lees of wine, though without possessing all its properties. The greater number of colouring principles and all topazuline; they are soluble by the action of the extractive matter, and, upon cooling, tend to form a solid form.

**WINE-SPRINT.** A term used by our distillers, and which may seem to mean the same thing with the phrase of spirit of wine; but they are taken in very different senses in the trade.

Spirit of wine is the name given to the common malt spirit, when reduced to an alcohol, or totally inflammable state; but the phrase wine-spirit is used to express a very clean and fine spirit, of the ordinary proof strength, and made in England from wines of foreign growth.

The way of producing it is by simple distillation, and it is never rectified any higher than common bubble-proof. The several wines of different names yield very different proportions, but, in general, the strongest yield one-fourth, the weakest in spirits one-eighth part of proofspirit; that is, they contain from a sixteenth to an eighth part of their quantity of pure alcohol.

**WINNOWING-MACHINES.** Machines of this sort are in pretty general use, where threshing-mills, to which they may be attached, are not erected: they are made on different principles according to particular circumstances. Those contrived by Mr. Cor. of Leicester, or on Mr. Winlow's plan, are good implements, and will dress grain with much dispatch. And there are others which are employed in the northern districts, which are made by Rodgers, that are also upon good and convenient principles; as well as many more in different places which have great merit in their construction, and do their work well and expeditiously. They are made of different sizes, from three to five or six persons will gain last many years when the materials of which they are formed are of a proper kind.

**WINTER.** A genus of plants of the class polymen; and in the natural system arranged under the 12th order, holarabian. The calyx is three-lobed; there are six or twelve petals; there is no style; the fruit is a berry, which is club-shaped as well as the genmer. There are three species, the aromatica, grandis, and ancilla.

Winter aromatic is one of the largest forest-trees upon Terra del Fuego; it often rises to the height of 50 feet. Its outward bark is on the trunk grey and very little wrinkled, on the branches quite smooth and green. The branches do not spread horizontally, but are bent upwards, and form an elegant head of an oval shape. The leaves come out without order, of an oval elliptic shape, quite entire, obtuse, flat, smooth, shining, of a golden yellow; they are softly downy on the upper side of a lively deep-green colour, and of a pale bluish colour underneath, without any nerves, and their veins scarcely visible; they are somewhat narrower near the foot-stalks, and there their margins are bent downwards. In general, the leaves are from three to four inches long, and between one and two broad; they have veined four short football stalks, seldom half an inch long, which are smooth, concave on the upper side, and convex underneath. From the seeds of the old foot-stalks the branches are often tuberculated.

**WIRE.** A piece of metal drawn through the hole of an iron into a thread of a fineness answerable to the hole it passed through. Wires are frequently drawn so fine as to be wrought along with other threads of silk, wool, flax, &c.

The metals most commonly drawn into wire, are gold, silver, copper, and iron. Gold wire is made of cylindrical agosts of silver, covered over with a skin of gold, and thus drawn successively through a vast number of holes, each smaller and smaller; till at last it is brought to a fineness exceeding that of a hair. That admirable ductility which makes gold wire so useful is so small, that no wire other than gold wire is made of it.

Silver wire is the same with gold wire, except that the latter is gilt, or covered with gold, and the former is not.

There are also gold-covered and silver wires: the first made of a cylinder of copper, silvered over, and then covered with gold; and the second of a like cylinder of copper, silvered over, and drawn through the iron, after the same manner as gold and silver wire.

Brass wire is drawn after the same manner, as the former. Of this there are divers sizes, suited to different sorts of works. The finest is used for the heads of musical instruments, as harpsichords, &c.

The pin-makers likewise use vast quantities of brass wire, to make their pins of.

Iron wire is drawn of various sizes, from half an inch to one-eighth of an inch diameter, and even smaller.

The first iron that runs from the stone when melting, being the softest and toughest, is preserved to make wire of. Iron wire is made from bars of iron, called electrode-iron, which are first drawn out to a greater length, and to whatever the thickness of the little finger, at a furnace, with a hammer gently moved by water; one, two, or three pieces are bored round, and put into a furnace to anneal for 12 hours. A pretty strong fire is used for this operation. After this they are laid under water for three or four months, the longer the better; then they are delivered to the workmen, called rippers, who draw them into wire through two or three holes. After this they anneal them again for six hours, and water them a second time for about a week, and then draw them again to the rippers, who draw them into wire of the thickness of large packthread. They are then annealed a third time, and then watered for a week longer, and delivered to the small wire-drawers, called overhouse-men.

In the mill where this work is performed, there are several barrels hooped with iron, on each of which hang two links, which stand across, and are fastened to the two ends of the tonge which catch hold of the wire, and draw it through the hole. The axis on which the tonge runs does not run through the centre, but is placed on one side, which is on which the hooks are placed; and underneath there is fastened to the barrel a spoke of wood, which they call a swingle, which is drawn back a good way by the cogs in the axis of the wheel, and draws back the barrel, which falls to again by its own weight. The tongs hanging on the hooks of the barrel, are by the workmen fastened to the end of the wire, and by the force of the wheel, the hooks being pulled back, draw the wire through the holes. The plate in which the holes are, is iron on the outside, and steel on the inside; and the wire is anointed with train-oil, to make it run the easier.

**WIRE OF LAPLAND.** The inhabitants of Lapland have a sort of shining slender substance in use among them on several occasions, which is made of the thickness and structure of a well-fed hair, yet smaller. They are called by those who do not examine its structure or substance, Lapland wire. It is made of the sinews of the reindeer, which being carefully separated in the eating, are, with the sinew, after sucking the sinews, fastened directly with tin, and being spun, formed into a thread, or small silver, and of admirable fineness and strength, when wrought to the smallest filament; but when longer, is very strong, and fit for the purposes of strength and ornament. Their wire, as it is called, is made of the finest of these threads, covered with tin. The women do this business; and the way they take it is to melt a piece of tin, and placing at the edge of it a horn with a hole through it, they draw these sinews threads, covered with the tin, through the hole, which prevents their coming out too thick covered. This drawing is performed with their teeth; and there is a single piece of bone placed at the top of the horn, and the wire is made flat, so that we always and it rounded on all sides but one, where it is flat.

This wire they use in embroidery their clothes, as we do gold and silver; they often sold it to strangers for the notion of having certain magical virtue.

**WITCHCRAFT.** By 9 G. II, c. 5, no prosecution shall be commenced or carried on against any person for witchcraft, sorcery, enchantment, or conjuration; or for charging another with any such offence.

But if any person shall pretend to exercise or use any kind of witchcraft, sorcery, enchantment, or conjuration, and undertake to tell fortunes, or pretend from his skill or knowledge in any occult or crafty science, to discover where, in what manner, any goods supposed to have been stolen or lost, may be found; he shall be imprisoned for a year, and once in every quarter of that year stand openly on the pillory for an hour; and further shall be bound to 'good behaviour' as the court shall award.

**WITENA-MOT, or WITENA-GEMOT, among the Saxons.** A term which literally signified the assembly of the wise men, and was applied to the great council of the nation, of latter days called the parliamet.
WITHERINGIA, a genus of plants of the class and order triandra monogynia. The corolla is sub-campanulate; calyx very small, four-toothed; perianthium twofold. There is one species, herb of South America.

WITZENIA, one of the plants of the class and order triandra monogynia. The corolla is one-petalled; stigma emarginate; capsule superior. There is one species, herb of the Amazon.

WITTERNAM, in law, a writ that lies where a distress is driven out of the county, and the sheriff cannot make delivery to the party distrained for; in that case this writ is directed to the sheriff, commanding him to take as many of the beasts, or goods, of the party into his keeping, till he make delivery of the first distress.

WITNESS, one who is sworn to give evidence in a cause.

A man is subpoenaed as a witness upon a trial, he must appear in court on pain of 100l., to be forfeited to the king, and 10l. together with damages equivalent to the loss sustained, by the want of his evidence to the party aggrieved.

But witnesses ought to have a reasonable time, that their attendance upon the court may be of as little prejudice to themselves as possible; and the court of king's-bench held, in that notice given in the forenoon to attend the sitting that evening at Westminster was too short a time. Str. 510.

Where a witness cannot be present at a trial, he may, by consent of the plaintiff and defendant, and by a rule of court, be examined upon interrogatories at the judge's chambers, and covered by oath.

No witness is bound to appear to give evidence in a cause unless his reasonable excuse is tendered him, and if he appears till such charge is actually paid him, except he be excused and is summoned to give evidence within the bills of mortality.

WOAD, in botany. See Isatis, and Indigo.

WOLF. See Canis.

WOLFHOLES, in the defence of places, are round holes, generally about two or three feet in diameter at the top, one at bottom, and two a half deep, dug in the front of any work. Sometimes a sharp-pointed stake or two are placed at the bottom, and covered with very thick planks, and green sods; consequently the enemy, on advancing, fall in, and are put into confusion.

WOLFRAM, a ore of tungsten, is found in different parts of Germany, in Sweden, Britain, France, and Spain; and almost constantly accompanied by ores of tin. It occurs both massive and crystallized. The primitive form of its crystals, according to the observations of Mr. Huy, is a rectangular parallelopiped, whose length is 8.06, whose breadth is 5.1, and thickness 4.33. It is not common, however, to find crystals of this perfect form in many cases: the angles, and sometimes the edges, of the crystal are wanting; as, Mr. Huy has shown, to the superposition of plates, whose edges or angles decrease according to a certain law.

WOOL.

greenish globule, and with microcrystalline salt a transparent globule of a deep red.

The specimen of this ore, examined by Messrs. d'Elhuyart, was composed of

- 65 oxide of tungsten
- 22 oxide of manganese
- 13 oxide of iron

Wool.

Another specimen from Puy-les-Mines in France, analysed by Vaquelin and Hecht, contained

- 67 oxide of tungsten
- 18.00 black oxide of iron
- 6.35 black oxide of manganese
- 1.50 silica
- 7.25 oxide of the iron and manganese

100.00

WOMEN. By the 26. G. II. c. 33, no suit shall be had in any ecclesiastical court, to compel a celebration of marriage in large ecclesiary, by reason of any contract of marriage whatsoever, whether per verba de præsentacil, or per verba de futuro: and the marriage of any person under the age of twenty-one, without the consent of parents or guardians, shall be null and void.

By 20. H. VI. c. 9 peers shall be tried as peers for treason or felony.

And by stat. 3 W. c. 9, a woman being convicted of an offence, for which a man may have his clergy, shall suffer the same punishment that a man should suffer, who has the benefit of his clergy allowed; that is, shall be burnt in the land, and further kept in prison until the court shall think fit, not exceeding one year.

But she shall be only once entitled to the benefit of the said statute.

WOOD, a solid substance, wherein the trunks and branches of trees consist. See the articles Tree, Trunk, Branch, Underwood, Plants, physiology of; Timber, &c.

The wood lies immediately under the bark, and forms by the greatest part of the trunk and large branches of trees. It consists of concentric layers, the number of which increases with the age of the part.

Each of these layers, as Mr. Duhamel ascertained, is separate from the others, and these are composed chiefly of longitudinal fibres. Hence the reason that wood may be much more easily split asunder than cut across.

The wood, when we inspect it with attention, is not, through its whole extent, the same: the part of it next the bark is much softer and whiter, and more juicy than the rest, and has for that reason obtained a particular name; it has been called the alburnum or aubier. The perfect wood is browner, and harder, and denser, than the alburnum, and the layers increase in density the nearer they are to the centre. Sir John Hill gave to the innermost layer of wood the name of corona; or rather he gave this name to a thin zone which, according to him, lies between the wood and the pith.

Mortimer observes that all kinds of wood are preserved from insects and from many other occasions of decay, by oily substances, particularly the essential oils of vegetables. Oil of spike is excellent; and oil of juniper, turpentine, or any other of this kind, will serve the purpose; these will prevent tables, instruments, &c. from being eaten by pieces by these vermin; and linseed-oil will serve, in many cases, to the same purpose; probably nut-oil will do also, and this is a sweeter oil, and a better varnish for woods. Some of the West Indian trees afford a sort of timber which, if it would answer in point of size, would have great advantages over any of the European wood in ship-building for the merchant-service, no worm ever touching this timber. The acacan, or tree which produces the cashew-nut, is of this kind; and there is a tree of Jamaica, known by the name of the white wood, which has exactly the same property; and so have many other of their trees.

To season wood expeditiously for sea-service, Mr. Boyle observes, that it has been usual to bake it in ovens.

The art of moulding wood is mentioned by Mr. Boyle as a desideratum in the art of carving. He says, he had been credibly informed of its having been practised at the Hague; and suspects that it might have been performed by some men who that softens the wood, and afterwards allows it to harden again, in the manner that was known; or moulded; or perhaps by reducing the wood into a powder, and then uniting it into a mass with strong but thin glue. And he adds, that, having mixed saw-dust with a fine glue made of isinglass, slightly straining out what was superfluous through a piece of linen, the remainder, formed into a ball, and dried, became so hard as to rebound when thrown against the floor.

The people who work much in wood, and about small works, find a very surprising difference in it, according to the different seasons at which the tree was cut down; and this not regularly the same in regard to all species, but different in regard to each. The button-mould makers find that the wood of the pear-tree, cut in summer, works toughest; holy, on the contrary, works toughest when cut in winter; box is mellowest when it has been cut in summer, but hardest when cut about the Easter; hawthorn works mellow when cut about October, and the service is always tough if cut in summer.

WOOD STAINING.

To stain wood yellow. Take any white wood, and brush it over several times with the tincture of turmeric root, made by putting an ounce of turmeric, ground to powder, to a pint of spirit, and after they have stood for some days, straining off the tincture. If the yellow colour is desired to have a reddish cast, a little dragon's blood must be added.

A cheaper, but less strong and bright yellow is, by the tincture of French berries made boiling-hot.

Wood may also be stained yellow by means of aqua fortis, which will sometimes produce a very beautiful yellow colour, but at other times a browner. Care must be taken, however, that the aqua fortis is not too strong; otherwise a blackish colour will be the result.

To stain wood red. For a bright red stain for wood, take a strong infusion of Brazil wood in stale urine, or in water, coloured with pearl-ashes, in the proportion of an ounce to a gallon; to a gallon of either of which, the proportion of Brazil wood must be
pound, which being put to them, they must stand together for two or three days, often stirring the mixture. With this infusion strained, and made boiling-hot, brush over the wood to be stained till it appears strongly colored; then, while yet wet, brush it over with alum-water made in the proportion of two ounces of alum to a pint of water.

For a less bright red dissolve an ounce of dragon's blood in a pint of spirit of wine, and brush over the wood with the tincture till the stain appears to be as strong as is desired; but this, in fact, rather lacquering than staining.

For a pink or rose red, add to a gallon of the above infusion of Brazil wood two additional ounces of the pearl-ashes, and use it as was before directed: but it is necessary, in this case, to brush the wood over with alum-water. By increasing the proportion of pearl-ashes, the red may be rendered yet paler; but it is proper, when more than this quantity is added, to make the alum-water stronger.

A stain wood blue may be stained blue by means of either copper or indigo.

The method of staining blue with copper is as follows: Make a solution of copper in aqua fortis, and brush it while hot several times over the wood; then make a solution of pearl-ashes in the proportion of two ounces to a pint of water, and brush it over the wood stained with the solution of copper, till it is of a perfectly blue colour.

Dissolve verdigris in vinegar, or crystals of verdigris in water, and with the hot solution brush over the wood till it is duly stained.

To stain wood purple. Brush the wood to be stained several times with a strong decoction of logwood and Brazil, made in the proportion of one pound of the logwood, and a quarter of a pound of the Brazil, to a gallon of water, and boil for an hour or more. When the wood has been brushed over till there is a sufficient body of colour, let it dry, and then be slightly passed over by a solution of one drachm of pearl-ashes in a quart of water. This solution must be carefully used, as it will very much change the colour from a brown red, which it will be originally found to be, to a dark blue purple, and therefore its effect must be restrained to the due point for producing the colour desired.

To stain wood mahogany colour. The substances used for staining mahogany colour are madder, Brazil wood, and logwood: each of which produces reddish brown stains, and they must be mixed together in such proportions as will produce the tint required.

To stain wood black. Brush the wood several times over with a hot decoction of logwood. Then having prepared an infusion of galls by putting a quarter of a pound of powdered galls to two parts of water, and setting them in the sunshine, or any other gentle heat, for three or four days, brush the wood over three or four times with it, and it will be a beautiful black. It may be polished with a hard brush and shoemakers' black wax.

Wood, fossil: whole trees, or parts of them, are very frequently found buried in the earth, and that in different strata; sometimes in stone, but more usually in earth, but sometimes in small pieces loose among gravel. See PETRIFICATION.

WOODCOCK. See the article Scolo-

WOODCOCK-SHELL, in natural history, the varnished yellow purpura, with tuber-
cles, and a long book; and the thorny wood-
cock-shell is the yellow long-beaked purpura, with long and crooked spines.

WOODCOCK-WOOD. See Oniscus.

WOODCOCK-WOOD, or Yellow wood. See the article Scolo-

WOOD, among manufacturers, the threads which the weavers shoot across with an instru-
ment called the shuttle. The wood is of dif-
f erent matter, according to the piece to be wrought. In taffety, both wood and warp are silk. In mohair, the wood is usually wool, and the warp silk. In satins, the warp is frequently flax, and the wood silk.

WOOL, a kind of long, soft, curly hair (see the article Hair), which covers the skin of several of the ruminating animals, but which is particularly cut or torn from that of the sheep, is in such universal use, that we should think it must be one of those animal substances most accurately known; it is, however, only within the last few years, that chemists have occupied themselves with examining it. Formerly, they contented themselves with considering it as diffusing a disagreeable smell when it was burned. As it yields a much richer spirit of ammonia, by dis-
tillation. It had been remarked in common life, that it did not inflame without great dif-
culty, and that it exhaled a very faint smoke, instead of taking a bright flame. Eventually, it was known, that the caustic alkalies easily corroded it, and that it quickly received, and forcibly retained, the colouring matters that were impressed upon it, so that it deserved the first rank amongst the substances to be dyed. It is eminently useful, to which it has been appropriated in a number of arts from time immemorial, has brought all its useful properties to light; but chemis-
try had considered it only under its most gen-
eral relation with all the animal matters, without ascertaining any thing specific in it. Berthollet began to occupy himself particu-
larly with it in 1784 and 1785. He has shewn that the caustic alkali less dissolves and entirely destroys it from this solution; in combination, he has sought the mode of action which the alka-
lies exert upon animal substances, and he has par-
ticularly availed himself of it, for explain-
ing the dyebility which exists between these two matters. In this manner he has especially accounted for the action of the lapis causticus, upon the bodies of the animals. He has, moreover, shown that the wool of wool was difficult to be burned, like that of all the animal compounds; that wool, treated by the nitric acid, afforded azotic gas, and oxalic acid, with a fatty matter. Chap-
tal, applying this solution of wool in the alka-
lies, to the processes of the manufacture of cloth, has represented it as a soap of great utility for these manufactures, and very well adapted for being substituted instead of that which is fabricated with vegetable oil. Wool has, moreover, been considered as a very bad conductor of calor; and upon this principle, it has been explained, bow, by retaining that which exudes from our bodies, it forms the warmest clothing, the best adapted for moder-
ating the severity of the winters. See Hair.

The facts contained in the article to which we refer, will explain all the phenomena, and all the properties which wool presents, in the frequent and advantageous uses to which it is constantly applied. The warmth which it affords as clothing or covering, its imperme-
ability by water, its fine colouration, the durabil-
ity and solidity of its dyes, its destruction by the alkalis, the facility with which grease is removed from the wool, and the elasticity and the best extension of the spots which are formed upon it, even the use which it has, and the functions which it per-
forms upon the bodies of those animals which are covered with it, and from which we take it in order to clothe ourselves; the adherent hair of the cat and fowl oil; the exudation with which it is impregnated upon the bodies of sheep; the manner in which it defends them against the rain and the water, which are so hurtful to it; its slow combustion; the yellowness and loss of tenacity that are produced in it by long exposure to the air: in a word, all that appertains to its characters, its formation, its use, its so various properties, its destruction, becomes clear and easily conceivable by the distinct determination of its nature, and of its composition.

WOOD, either in a raw or manufactured state, has always been the principal of the materials used in manufacture. The price of wood was in very early times much higher in proportion to the wages of labour, the rent of land, and the price of butcher's meat, than at present. It was before the time of Edward III., always exported raw, the art of working it into cloth and dyeing being so imperfectly known, that no persons above the degree of working people could go dressed in cloth of English manufacture.

The first steps taken to encourage the manufacture of woollen cloths was by Edward the Third, who procured some good workmen from the Netherlands by means of protection and encouragement. The value of wood was considered as so essentially solid, that taxes were voted in that commodity, reckoning by the number of sacks, and in proportion to the price of the necessaries of life and value of silver, wool was at least three times dearer than it is now. The manufacturing of cloth was everywhere within a few years, the policy of preventing the exportation of the raw material was soon evident; and the first act, was that of H. IV. c. 2, by which the exportation of sheep, lambs, or rams, is forbidden under heavy penalties.

By stat. 28. Geo. III. all former statutes respecting the exportation of wool and sheep are repealed, and numerous restrictions are consolidated in that statute.

By this act, if any person shall send or re-
cive any sheep on board any vessel, to be carried out of the kingdom, such vessel shall be forfeited, and the person so offending shall forfeit 3l. for every sheep, and suffer solitary imprisonment for three months. But when sheep, by a licence from the collector of the customs, may be taken on board for the use of the ship's company; and every person who shall export any wool, or woollen articles slightly made up, so as easily to be reduced again to wool, or any fuller's earth or tobaco-
pipe clay, and every carrier, ship-owner, com-
mander, mariner, or other person, who shall knowingly assist in exporting, or at-
tending to export, these articles, shall forfeit three shillings for every pound weight, or the sum of 50l. in the whole, at the election of the prosecutor, and shall also suffer solitary imprisonment for three months. But wool
may be carried coastwise upon being duly entered, and security being given according to the directions of the statute, to the officer of the port whence the same shall be conveyed; and the owners of sheep within five miles of the sea, and two miles in Kent and Sussex, cannot remove the wool; without giving notice to the officer of the nearest port, as directed by the statute.

WOollen Cloth, interment in. By 30 G. II. c. 3. (an act which is required to be given in charge at the assizes and sessions, and to be read four times publicly each year in the church by every person,) no corpse of any person (except of those who die of the plague) shall be buried in any shirt, shift, sheet, or shroud, or any thing made or mingled with flax, hemp, silk, hair, gold, or silver, or in any stuff or thing not made of sheep's wool only; or be put into any coffin lined or faced with any sort of clothier-stuff, or any other thing, made of any other material than sheep's wool only, under penalty of $L. to be recovered by distress and sale of the goods and chattels of the party deceased.

Woot-cloths. By 33 G. III. c. 104, all those who have served an apprenticeship to the trade of a wool-comber, or who are by law entitled to exercise the same, and also their wives and children, may set up and exercise such trade, or any other trade or business they are apt and able for, in any town or place within this kingdom, without any molestation; nor shall they be removable from such place by the poor laws.

The singular, signifies signal, token; for, as watch-word, &c.

The Word, is a peculiar word that Watch Word, serves for a token and mark of distinction, given out in the orders of the day in times of peace, but in war every evening in the field, by the general who commands, and in garrison by the governor, or other officer commanding in chief, to prevent surprise, and hinder an enemy, or any treacherous person, from passing backwards or forwards. This watch-word is generally called the parole, and to it is added the countersign. The first is known to all officers and non-commissioned officers; the latter only to the sentinel and such guards that go to the rounds, or patroles, exchange the word with the officers on duty; nor must the sentinels let any one pass who has notgot the countersign.

Words of command, certain terms which have been adopted for the exercise and movement of military bodies, according to the nature of each particular service. Words of command are classed under two principal heads, and consist of those which are given by the chief of command, that is, by a general, or division, or division of, and those which are uttered by the subordinate leaders of troops, &c.

WORD, in language, an articulate sound, representing some idea or conception of the mind.

The copiousness of the English language is proved by the following enumeration of the words in Johnson's Dictionary:

It must be remarked, however, that in this list many of the compound words are not reckoned; that the participles are those only having no verbs to which they may be referred, as behold; though so few verbal and participal nouns are stated by Johnson, yet every active verb may supply one of the former description, and every verb one of the latter; and that both these (verbal and participal nouns) seem to be merely different applications of a true gerund.

WORDS, which may be taken or interpreted by law in a general or common sense, ought not to receive a strained or unusual construction; and ambiguous words are to be construed so as to make them stand with law and justice, and not to be wrested to do wrong.

WRECK, is a judicial writ that issues out of the sheriff, upon a judgment by default, in action of the case, covenant, trespass, trover, &c; commanding him to summon a jury to inquire what damages the plaintiff has sustained occasioned by the original is returned, after the suit begins. The original bear date in the name of the king; but the judicial writs bear teste in the name of the chief justice.

WRIT of Asssistance, issues out of the exchequer, to authorize any person to take a constable, or other public officer, to seize goods or merchandise prohibited and uncustomed. It is also a writ issuing out of the chancey, for the summoning a defendant to appear, and are granted before the suit is begun, to begin the same; and judicial writs of this sort cannot be quashed till the original is returned, after the suit begins. The original bear date in the name of the king; but the judicial writs bear teste in the name of the chief justice.

WRIT of Assistance, issues out of the exchequer, to authorize any person to take a constable, or other public officer, to seize goods or merchandise prohibited and uncustomed.

WURMBA, a genus of plants of the class and order Dianthrea monogynia. The corolla is tubular, ligulate, with the upper lip small, the lower lip three-lobed, the outer lobe five-parted, the inner lobe two-parted, the tube four-valved. There is one species, herb of Carinthia.
X or x, the twenty-second letter of our alphabet. In numerals it expresses 10, whence in old Roman manuscripts it is used for denarius; and as such seems to be made of two V's placed one over the other. When a dash is added over it, thus X, it signifies ten thousand.

XANTHELE, a genus of plants of the class and order dioecia syngenemia. The flowers are dioecious; the calyx five-parted; corolla 5-6-petalled. There are two species, shrubs of Guatemala.

XANTHIB, a genus of plants of the class monocotyledon, order pentandria, and arranged in the natural classification under the 49th order, composita. The male flowers are composite, common calyx, fructified; corolla monopetalous, tubular, quinquelocular. Female: calyx involucre of two leaves, containing two flowers; corolla 0; drupa dry, prickly; nucleus bilocular. There are five species, only one of which is a native of Britain, the strumarium or less burdock. The stem of this plant is a foot and a half high, thick, often spotted; leaves heart-shaped, lobed, on long footstalks. Flowers, male and female, many together, in the axil of the leaves. The leaves are bitter and astringent. A decoction of the whole plant affords a showy yellow colour, but it is better if only the flowers are used. Horses and goats eat it; cows, sheep, and swine, refuse it.

XANTHIONYX, a genus of plants of the class and order pentandria polypogonia. There is no calyx; the petals five; nectaries five, pedicelled; capsules five, one-seeded. There is one species, a shrub of North America.

XANTHORZA, a genus of plants of the class and order pentandria polypogonia. There is no calyx; the petals five; nectaries five, pedicelled; capsules five, one-seeded. There is one species, a shrub of Jamaica.

XANTHEUM, a genus of the syn-

genesia polypogonia superful class of plants; the compound flower of which is unequal, and consists of many tubulous hermaphrodite floscles placed on the disc, and also a few female tubulolated ones on the verge; the seeds are oblong, coronated, and contained in the cup. There are twenty-seven species.

XIMENIA, a genus of plants of the class and order pentandria monogyne. The calyx is perianthium, composed of a small, corollated, and deciduous leaves; the corolla is formed of four petals, of a campanulate figure, divided at the edge into three erect, oblong, obtuse segments; the germen is small, and of a suboval figure; the fruit is an oval drupe, containing a cell; the seed is oval, microlocular, and smooth. There are three species, trees of the West Indies.

XIPHIAS, in zoology, the sword-fish, a genus of fishes belonging to the order of apodes. The upper jaw terminates in a long sword-shaped rostrum, from which it is called the sword-fish: there are no teeth in the mouth; the gill membrane has eight rays; and the body is somewhat cylindrical. There is but one species, viz. the gladius, found in the European ocean. This fish sometimes attains a length of one-third of a mile; and as occasion in the Mediterranean sea, especially in the part that separates Italy from Sicily, which has been long celebrated for it: the promontory Pelorus, now Capo di Faro, was a place noted for the resort of the vigiles, and possibly the station of the speculatores, or the person who watched and gave notice of the approach of the fish.

The ancient method of taking them is particularly described by Strabo, and agrees exactly with that practised by the moderns. A man ascends one of the cliffs that overhang the sea; as soon as he spies the fish, he gives notice, either by his voice or by signs, of the course it takes. Another, that is stationed in a boat, climbs up the mast, and on seeing the sword-fish, directs the rowsers towards it. As soon as he thinks they are got within reach, he descends, and taking a spear in his hand, strikes it into the fish; which, after wearying itself with its agitation, is seized and drawn into the boat. It is usually esteemed by the Sicilians, who buy it up eagerly, and at its first coming into season, give about six-pence English per pound. The season lasts from May till August. The antients used to cut this fish very fine, and called Tomus Thurianus, from Thuris, a town in the bay of Tarentum, where it was taken and cured.

The sword-fish is said to be very voracious, and that it is a great enemy to the tuna, who (according to Belon) are as much terrified at it as sheep are at the sight of a wolf. It is a great enemy to the whales, and frequently destroys them.

XIPHYDIDUM, a genus of plants of the class and order triandria monogyne. This corolla is scapellated, equal; capsules superior, three-celled, many-seeded. There is one species, a herb of the West Indies.

XYLO ALOES, or ALO-WOOD, in pharmacy. See Excercaria.

XYLOGCARUS, a genus of plants of the class and order octandria monogyne. The calyx is four-toothed; the corolla four-petalled; nectaries eight-cleft; filaments inserted in nect. drupes four or five-grooved; nuts eight or ten. There is one species, a tree of the East Indies.

XYLOLUM, a genus of plants of the class and order tetrandria monogyne. The ament, is with a simple scale; petals four, staminuliferus; stigma club-shaped, obtuse. There is one species, of no note.

XYLOPHYLLA, a genus of plants of the class and order polyanthra trigrina. The calyx is five-toothed, coloured; corolla none; one stigma, jagged; capsule three-celled; seeds two. There are seven species, shrubs of the West Indies.

XYLOFLA, a genus of plants of the class and order polyanthra polygynia. The calyx is three-leaved; petals six; capsule one or two seeded, four-cornered, two-valved; seeds arilled. There are three species, trees of the West Indies.

XYLOSMA, a genus of plants of the class and order dioecia polyanthra. The calyx is four or five parted; corolla none; male stamnia twenty to fifty; female style scarcely any; stigma trifid; berry dry; seeds two, three-seeded. There are two species.

XYRIS, a genus of the triandria monogyne class of plants, the flower of which consists of three plain, patent, large, crested petals, with narrow unguis, of the length of the cup. The fruit is a roundish, triloclar, trivalvular capsule, within the cup, with a great number of very small seeds. There are three species.

Y.

Y, the twenty-third letter of our alphabet. Y is a numeral, signifying 150, or according to Baronius, 159; and with a dash at top, as Y, it signified 150,000.

YACHT: This word is taken from the Dutch, from the Yacht, a small boat with one deck, carrying four, eight, or twelve guns, and thirty or forty men. Yachts, in general, are from thirty to 160 tons; contrived and adorned both withside and without, for carrying state pageants, etc. They answer the purposes of business as well as pleasure, being remarkably good sailers.

YARD. See Measure.

YARDS of a ship, are those long pieces of timber which are made a little tapering at each end, and are fitted each athwart its proper mast, with the sails made fast to them, so as to be hauled up, or lowered down, as occasion serves. They have their names from the masts to which they belong. As for the length of the main-yard, it is usually five-sixths of the length of the keel, or six-sevenths of the length of the main-mast. Their thickness is commonly three quarters of an inch for every yard in length. The length of the main-top-yard is two-thirds of the main-yard; and the fore-yard four-fifths of it. The spitsail-yard, and cross-sails yard, are half the main-yard; and the thick-knives, or the main-yard and spitsail-yard is half an inch for every yard in length. All small yards are half the great yards from cleat to cleat. When a yard is down a portail, it gives the length of all top-sail sheets, lifts, ties, and bunt-lines, as also of the leech-lines and halliards, measuring from the hounds to the deck; and when it is hoisted, it gives the length of clew-linens, clew-garnets, braces, tackles, sheets, and bow-lines.

There are several sea-terms relating to the management of the yard; as square the rounds, that is, see that they hang right across the ship, and no yard-arm traversed more than another; top yard, that is, make them stand even. To top the main and foreyards, the clew-linens are the most proper;
YAR

YAR, in the full extent of the word, is a system or cycle of several months, usually 12. Others define year, in the general, a period or space of time, measured out by the revolution of some celestial body in its orbit. In the heavens, the stars make but one revolution, is called the great year; and the times in which Jupiter, Saturn, the Sun, Moon, &c. complete their courses, and return to the same point of the zodiac, are respectively called the years of Jupiter and Saturn, and the solar and lunar years, &c.

As year denoted originally a revolution, and was not limited to that of the Sun; accordingly we find by the oldest accounts, that people have, at different times, expressed other revolutions by it, particularly that of the Moon; and consequently that the years of some accounts, are to be reckoned only months, and sometimes periods of 2, or 3, or 4 months. This will help us greatly in understanding the accounts that certain nations give of their own antiquity, and perhaps of the age of men. We read expressly, in several of the old Greek writers, that the Egyptian year, at one period, was only a month; and in another, it was a period of 3 months, or four months; and it is probable that the children of Israel followed the Egyptian account of their year. The Egyptians talked, almost 2000 years ago, of having accounts of events, 43,000 years distant. A great deal must be allowed to fallacy, on the above account; but beside this, the Egyptians had, in the time of the Greeks, the same ambition which the Chinese have at present, in which the fixed stars upon which people, as these do upon us, for the oldest inhabitants of the earth. They had recourse also to the same means; and both the present and the early impostors have pretended to ancient observations of the heavenly bodies, and recounted eclipses in particular, to vouch for the truth of their accounts. Since the time in which the solar year, or period of the earth's revolution round the Sun, is to be reckoned with certainty; but for those remote ages, in which we do not know with certainty what is meant by the term year, it is impossible to form any conjectures of the duration of time. The Egyptians pretend to an antiquity of the same romantic kind; they talk of 47,000 years in which they had kept observations; but we may judge of these as of the others, and of the observations as of the years. The Egyptians speak of the stars having four times altered their courses in that period which they claim for their history, and that the Sun set twice in the east. They were not such perfect astronomers, but, after a roundabout voyage, they might perhaps mistake the east for the west when they came in.

Year, or solar year, properly, and by way of eminence so called, is the space of time in which the Sun moves through the twelve signs of the ecliptic. This, by the observations of the best modern astronomers, contains 365 days, 5 hours, 48 minutes, 48 seconds; the quantity assumed by the authors of the Bible, and by all nations with regard to their periods, upon which the division is founded. By this, the various forms of civil years that have formerly obtained, or that do still obtain, in different nations, are to be examined. Civil year is that form of year which every nation has contrived or adopted, for compu-
ing their time by. Or the civil is the tropical year, considered as only consisting of a certain number of whole days; the odd hours and minutes, aside, to render the computation of time, in the common occasions of life, more easy. As the tropical year is 365 days, 5 hours, 49 minutes, or almost 365 days, 6 hours, which is 356 days and a quarter; but if the civil year is made 365 days, every fourth year it must be 366 days, to keep nearly to the course of the sun. And hence the civil year is either common or bissextile. The

Common civil year, is that consisting of 365 days; having seven months of thirty-one days each, four of thirty days, and one of twenty-eight days; as indicated by the following well-known memorial verses:

Thirty days hath September, April, June, and November;
February twenty-eight alone,
And all the rest have thirty-one.

Bissextile or leap-year, consists of 366 days, having one day extraordinary, called the intercalary, or bissextile day, which takes place every fourth year. This additional day to every fourth year, was first introduced by Julius Caesar; who, to make the civil year keep step with the tropical year, contrived that the six hours which the latter exceeded the former, should make one day in four years, and be added between the 23rd and 24th of February, which was their sixth of the calends of March; and so they then counted this day twice over, or had six sexto calenda, hence the year itself came to be called bis sextus, and bissextile.

Among us, however, the intercalary day is not introduced by counting the 23rd of February twice over, but by adding a day at the end of that month, which therefore in that year contains 29 days.

The civil or legal year, in England, formerly commenced on the day of the anunciation, or 25th of March; though the historical year began on the day of the Circumcision, or 1st of January; on which day the German and Italian year also begins. The part of the year between these two terms was used by the ancients both ways; as 1745, or 1744. By the act for altering the style, the civil year now commences with the 1st of January.

Antient Roman year. This was the lunar year, which, as first settled by Romulus, contained only ten months, of unequal numbers of days, in the following order: viz.

March 31, April 30, May 31, June 30, Quintilis 31, Sextilis 30, September 30, October 31, November 30, December 30, in all 304 days, which came short of the tropical lunar year by 50 days, and of the solar by 61 days. Hence the beginning of Romulus's year was vague, and unfixed to any precise season; to remove which inconvenience, that prince ordered so many days to be added yearly as would make the state of the heavens correspond to the first month, without calling them by the name of any month.

Numa Pompilius corrected this irregular constitution of the year, containing two new months, January and February, not belonging to the days that were used to be added to the former year. Thus Numa's year consisted of twelve months, of different days, as follow; viz.

<table>

This is called the Gregorian, or New Style, and the Julian, or Old Style.

As the Egyptian year, by neglecting the 6 hours, in every 4 years loses a whole day of the Julian year, its beginning runs through every part of the Julian year in the space of 1460 years; after which, they meet again, for which reason it is called the erratic year. And because this return to the same day of the Julian year, in the space of 1460 Julian years, this circle is called the Sothic period.

This year was applied by the Egyptians to civil uses, till Anthony and Cleopatra were defeated; but the mathematicians and astronomers used it till the time of Ptolomy, who made use of it in his Almagest; so that the knowledge of it is of great use in astronomy, for comparing the ancient observations with the modern.

The antient Egyptians, we are told by Diodorus Siculus, measured their years by the course of the moon. At first they were only one month, then 3, then 4, like that of the Arcadians; and then 6, like that of the people of Arcamania. Those authors add, that it is on this account that they reckon a vast number of years from the beginning of the world; and that in the history of their kings, we meet with some who lived 1600 or 1200 years. By such means many account for the great ages of the ancient patriarchs; expounding the gradual decrease in their ages, by the successive increase of the numbers.
although with some alteration; for they still retained their ancient months, with the five additional days; and every fourth year they intercalated, for the 6 hours, at the end of the year, or between the 28th and 29th of August. Also, the beginning of their year, or the first day of the month Thoth, answered to the 29th of August of the Julian year, or to the 29th if it happened to be leap-year.

The ancient Greek year, was a lunar year, consisting of 12 months, which at first had each 30 days, then alternately 29 and 30 days, corresponding to the first appearance of the new moon; with the addition of an embolic month of 30 days, every 3d, 5th, 7th, 11th, 14th, 16th, and 19th year of a cycle of 19 years; in order to keep the new and full moons to the same terms or seasons of the year.

Their year commenced with that new moon which was nearest to the summer solstice. And the order of the months, with the number of their days, were as follows: 1. Apros; 2. Bounymus; 29 of 29 days; 3. Hahase; 4. Mascaram; 5. Jornada; 6. Sabat; 7. Ty; 8. Rabia; 9. Tisri; 10. Jacatil; 11. Di mel; 12. Assirer.

The Athenian, Macedonian, and Turkish year, called also the year of the Hegira, is a lunar year, equal to 334 days, 8 hours, 48 minutes, and consists of 12 months, containing alternately 30 and 29 days; although sometimes it contains 13 months; the names &c. being as follows: 1. Muharram of 30 days; Saphar 29; Rabia 30; 4. Latt-er Rabia 29; 5. Jomada 30; 6. Lutter Jomada 30; 7. Rajab 30; 8. Shaaban 29; 9. Ramazan 30; 10. Shwav; 11. Dulkahat 30; 12. Dhulhijja 29, in the embolic month 30. An intercalary day is added every 2d, 5th, 7th, 10th, 13th, 16th, 18th, 21st, 24th, 29th, 30th, in a cycle of 29 years. This day is reckoned from the first appearance of the new moons after the conjunction.

YEADEGERDIC YEAR. See Persian Year.

YEAR and DAY, it is a time that determines a right in many cases; and in some works an usurpation, and in others a prescription; as in case of an estray, if the owner, proclamation being made, challenges it not within the time, it is forfeited.

No is the year, and day a day given in case of appeal; in case of descent after entry or claim, if no claim upon a fine or writ of right at the common law. So of a villain remaining in ancient demesne; of a man sore bruised or wounded; of protections; essuins in respect of the king's service; of a wreck; and divers other cases. Co. 6. Rep. Foi. 107.

YEAR BOOKS, reports in a regular series, from Ed. II. inclusive, to the time of Henry VIII., which were taken by the prothonotaries of the court, at the expense of the crown, and published annually.

YEAR DAY and WASTE, is a part of the king's prerogative whereby he challenges the profits of their lands and tenements for a year and a day, that are attainted of petty treason or felony; whoever is lord of the manor where the lands or tenements belong; and not only so, but in the end may waste the tenements, destroy the houses, root up the woods, garden, and pasture, and plough up the meadows, except the lord of the fee agrees with him for redemption of such waste, after having 20 days' notice, or the lord of the fee. Stann. Probat. c. 16.

YEARS, estate for. Tenant for term of years, is where a man lets lands or tenements to another, for a certain term of years agreed upon between the lessor and lessee; and when the lessee enters by force and the lessor is at the time to be liable, then he is tenant for term of years. Litt. Sect. 38.

If tenements are let to a man for the term of half a year, or for a quarter of a year, or any less, it is not for a certain term for years, and is styled in some legal proceedings, a year being the shortest term, which the law in this case takes notice of. Litt. Sect. 67.

Generally, every estate which must expire at a period certain and prefixed, by whatever words created, is an estate for years; and therefore this estate is frequently called a term; because its duration or continuance, is bounded, limited, and determined. 2 Black. 143.

For every such estate must have a certain beginning, and certain end. If no day of commencement is named in the creation of this estate, it begins from the making, or delivery of the lease. A lease for so many years as such an one shall live, is void from the beginning; for it may determine sooner, or it can ever be reduced to a certainty, during the continuance of the lease. Id.

And the same doctrine holds, if a person makes a lease of his glebe for so many years as he shall continue parson of such a church, for this is still more uncertain. But a lease for twenty or more years, if the parson shall so long live, or if he shall so long continue parson, is good; for there is a certain period fixed, beyond which it cannot last, though it may determine sooner, on the parson's death, or his ceasing to be parson there. 2 Black. 143.

An estate for years, though ever so many, is inferior to an estate for life. For an estate for life, though it should be only for the life of another person, is a freehold; but an estate, though for a thousand years, is only a chattel, and reckoned part of the personal estate. Id.

Hence it follows, that a lease for years may be made to continue in futuro, though a lease for life cannot. As if I grant lands to one from Michaelmas next for twenty years, this is good; but to hold from Michaelmas next for the term of his natural life, is void. 2 Black.

For no estate of freehold can commence in futuro, because it cannot be created at common law without livery of seisin, or corporal possession of the land; and corporal possession cannot be given of an estate now, which cannot commence now, but hereafter. And because no livery of seisin is necessary for a lease for years, such a lessee is not said to be seized, or to have true legal seisin of the lands. Nor indeed does the bare lease vest any estate in the lessee, but only gives him a right of entry on the tenement, which right is called his interest in the term; but when he has actually so entered, and thereby accepted the grant, the estate Michaelmas next vested in him; and he is possessed, not properly of the land, but of the term of years, the possession or seisin of the land remaining still in him who has the freehold. 2 Black.

YELLOW. See DOLPHIN-HAMMER. See EMERIZA.

YEMAN, is defined to be one that has fee land of 40/- a year; who was thereby hereafter qualified to serve on juries, and
can yet vote for knights of the shire, and do any other act where the law requires one that is probus et leges homo. Below yeomen are ranked tradesmen, artificers, and labourers. 2 Inst. 668.

Yeoman of the guard, one belonging to a sort of foot guards, who attend at the palace. The yeomen were uniformly required to be six feet high. They are in number 100 on constant duty, and 70 off duty. The one half carry arquebuses, and the other pertas. Their attendance is confined to the sovereign's person, both at home and abroad. They are clad after the manner of king Henry VIII.

The yeomen of the guards were anciently 250 men of the next rank, under gentry. This corps was first instituted by king Henry VII, anno 1466.

YEST, YEAST, or BARM, a head or scum, rising upon beer or ale, while working or fermenting in the vat. See Fermentation.

YOK, or Yoke, in agriculture, a frame of wood, fitted over the necks of oxen whereby they are coupled together, and harnessed to the plough. See Plough.

It consists of several parts: as the yoke, properly so called, which is a thick piece of wood, lying over the neck; the bow, which compasses the neck about; the stirrups and forwarding, which hold the bow fast in the yoke; and the yoke-rings and ox-chain.

The Romans made the cannon they subdue, pass under the yoke, which they called sub jugum mittere, that is, they made them pass under a sort of furca pustulare, or gallow, consisting of a piece of iron or some weapon, laid across two others, planted upright in the ground.

YORK. In the county of York, only one panel of 48 jurors shall be returned to serve on the grand jury at the assizes; and at the quarter-sessions not above 40, either upon the grand jury or other service there. 7 and 8 W. III, c. 32.

And no person having 100l. a year, shall be summoned to the sessions, but only persons less liable to bear the expense of attending at the assizes. 1 Anne, c. 13.

By stat. 4 W. III, c. 2, the inhabitants of the province of York, have power to dispose of the crown's estate by will which before they had not, further than the testator's own proportionable part, called the dead man's or death's part. For if the testator had a wife, and a child, or children, the wife should have one third, the child or children another third, and the remaining third was all that the testator had to dispose of. If he had a wife and no child, then she should have one moiety, and the other moiety remained to him to dispose of by his testament; so if he left a child or children, and no wife. But if he had neither wife or child, he might dispose of the whole. In case of intestacy, the same proportion continue to the wife and children to this day; but the dead man's part shall be distributed according to the stat. 22 and 23 Car. II, c. 10, commonly called the statute of distributions.

YTRIA. Some time before 1788, Captain Arhenius discovered in the quarry of Ytterby in Sweden, a peculiar mineral different from all those described by mineralogists. Its colour is greenish-black, and its fracture like that of glass. It is magnetic, and generally too hard to be scratched by a knife. If it is opaque, except in small pieces, when it transmits some yellow rays. Its specific gravity is 4.237. Professor Gadolin analysed this mineral in 1794, and found it to form a new earth; but though his analysis was published in the Stockholm Transactions for 1794, and in Cleel's Annals for 1796, it was some time before it drew the attention of chemical mineralogists. The conclusions of Gadolin were confirmed by Ekeberg in 1797, who gave to the new earth the name of yttria. They were still farther confirmed and extended by Vauquelin in 1800, and likewise by Lavoisier about the same time; and Ekeberg has published a new dissertation on the subject in the Swedish Transactions for 1802. We may therefore consider the peculiar nature of yttria as sufficiently established.

TTROANTALITE, a mineral found in the same place with gadolinite. It is in small kidney-form masses of the size of a hazel-nut. Fracture granular, iron-grey, and of a metallic lustre. Hardness inconsiderable. May be scratched with a knife, and gives a grey-coloured powder. Not magnetic. Specific gravity 5.130. It is composed of the oxides of tantalum and iron united to yttria.

YUCCA, Adam's needle, a genus of plants of the class hexandria and order monogynia. The corolla is campanulate and patent, there is no style, the capsule is trilocular. There are four species, none of which are natives of Britain. All of them are exceedingly curious in their growth, and are therefore much cultivated in gardens. The Indians make a kind of bread from the roots of this plant.

YUNX, in zoology, a genus of birds of the order picex. The bill is short, roundish, and pointed; the nostrils concave and naked; the tongue very long and cylindrical; there are two fore and two hind claws. There is only one species, the torquilla, wry-neck, which is a native of Europe, Asia, and Africa, and is often seen in Britain. It is ash-coloured above, with light black and brown strokes; beneath light-brown, with black spots; tail ash-colour, with four black bars; weight 1 oz.; irides hazl; length seven inches; migrates.

Z.

Z, the twenty-fourth and last letter of our alphabet.

In abbreviations this letter formerly stood as a mark for several sorts of weights; sometimes it signified an ounce and a half, and very frequently it stood for half an ounce; sometimes for the eighth part of an ounce, or a dram troy weight; and it has in earlier times been used to express the third part of an ounce, or eight scruples. ZZ were used by some of the ancient physicians to express myrrh, and at present they are often used to signify zincifer, or ginger.

ZAFFRE, the oxide of cobalt, employed for painting porcelain and cobalt of a blue colour. See Cobalt.

ZAMIA, a genus of the natural order of palmaceae. The amant is shiobe-shaped; scales with pollen underneath; frut. amant shioblé-shaped with scales at each margin; berry solitary. There are five species.

ZANNICHHELLA, horaced pond-weed, a genus of the monoece monandria class of plants, the male flower of which consists only of a single stamen, it is calyce nor corolla. In the female flower the calyx is composed of a single leaf; there is no co-
The peculiar the calyx Is Way, rumale
of its crystal is a rectangular prism, whose bases are squares. The most common variety is a long four-sided prism, terminated by low four-sided pyramids.

Its texture is strated or fibrous. Its lustre is silky. Reflects double. Absorbs water. Specific gravity 2.0833. Colour white, often with a shade of red or yellow. When heated it becomes electric, like the tournamule. Before the blow-pipe it frotts, emits a phosphorescent light, and pellets into a white semi-transparent enamel, too soft to cut glass, and soluble in acids. In acids it dissolves slowly and partially without effervescence; and at last, unless the quantity of liquid is too great, it is converted into a jelly. A specimen of zeolite, analysed by Vauquelin, contained

53.00 silica
27.00 alumina
9.48 lime
10.00 water
90.46.

ZEUS, in mythology, a genius of fires of the order of thoracite. The heat is compressed and declines, the upper lip being vaulted over by a transverse membrane; the tongue is subulate; there are seven rays in the Gill-membrane; and the body is compressed. The species are eight, of which the most remarkable is the faber or doree. It is of a hideous form; its body is oval, and greatly compressed on the sides; the head large; the snout vastly projecting; the mouth very wide, the teeth very small; the eyes great, the inles yellow; the lateral line oddly distorted, sinking at each end, and rising near the back in the middle; beneath it on each side is a round black spot. The tail is round at the end, and consists of fifteen yellow rays. The colour of the sides is olive, varied with light blue and white, and white living is very perceptible, and as if gilt; for which reason it is called the dorree. The largest fish we have heard of weighed twelve pounds. See Plate Nat. Hist. fig. 421.

ZIERIA, a genus of plants of the class monotaca, order tetradiatra monocaulon. The calyx is four-parted; styles simple; carpels four; seeds arilled: There is one species, not deserving notice.

ZINC. The antients were acquainted with a mineral to which they gave the name of cadmia, from Cadmus, who first taught the Greeks to use it. They knew that when melted with copper it formed brass; and that when burnt, a white spongy kind of ashes was volatilized, which they used in medicine. This mineral contained a good deal of zinc; and yet there is no proof remaining that the antients were acquainted with that metal. The word zinc first occurs in the writings Paracelsus, who died in 1534. He informs us very gravely, that it is a metal, and not a metal, and that it consists chiefly of the ashes of copper. This metal has also been called spelter. Zinc has never been found in Europe in a state of purity, and it was long before a method was discovered of extracting it from its ore. Henkel pointed out one in 1721; Von Swab obtained it by distillation in 1742; and Margraf published a process in the Berlin Memoirs in 1746.

Zinc is of a brilliant white colour, with a shade of blue, and is composed of a number of thin plates adhering together. When this metal is rubbed for some time between the fingers, they acquire a peculiar taste, and a very perceptible pervious smell; to which, however, is six and a half. When rubbed upon the fingers it tingles of a black colour. Its specific gravity, after it has been melted, is 6.61; after it has been compesed 7.1908; whilst its density is increased 1.987. This metal forms in a manner the limit between the brittle and the malleable metals. Its malleability is by no means to be compared with that of some of the metals; yet it is not brittle, like others. When struck with a hammer, it does not break, but yields and becomes somewhat flatter; and by a cautious and equal pressure, it may be reduced to a pretty thin plate, which are supple and elastic, but cannot be folded without breaking. This property of zinc was first ascertainment by Mr. Sage. When heated to about 400°, it becomes so brittle, that it may be reduced to powder in a mortar.

Zircone. It is not described. Zircon has not been ascertained. When heated to the temperature of about 700°, it melts; and if the heat is increased, it evaporates, and may be easily distilled over in close vessels. When allowed to cool slowly, it crystallizes into any of quadrangular prisms, disposed in all directions. If they are exposed to the air while hot, they assume a blue changeable colour.

When exposed to the air, its lustre is soon tarnished, but it scarcely undergoes any other change. When kept under water its surface soon becomes black, the water is slowly decomposed, hydrogen gas is emitted, and the oxygen combines with the metal. If the heat is increased, the decomposition goes on more rapidly; and if the steam of water is made to pass over zinc at a very high temperature, it is decomposed so rapidly, that very violent detonations take place.

When zinc is kept melted in an open vessel, its surface is soon covered with a grey-coloured pellicle, in consequence of its combination with oxygen. When this pellicle is removed, another soon succeeds, in which the whole of the zinc be oxidized. When these pellicles are heated and agitated in an open vessel, they soon assume the form of a grey powder, often having a shade of yellow. The powdered has been called the grey oxide of zinc. When zinc is raised to a very strong red heat in an open vessel, it takes fire, and burns with a brillian white flame, and at the same time emits a vast quantity of very light white flakes. These are merely an oxide of zinc. This oxide was well known to the antients. Dioscorides describes the method of preparing it. The antients called it pomptus; the early christians gave it the name of nihil album, and the flowers of zinc. Dioscorides compares it to wool. Two different oxides of zinc are present known.

The peroxide, or white oxide of zinc, is the oxide usually formed in the different processes to which the metal is subjected. We are indebted to Mr. Proust for an exact analysis of this oxide and its combinations. It is composed of eighty parts of oxygen and four parts of zinc. This oxide is formed not only by burning zinc, but also by dissolving...
it in diluted sulphuric or nitric acid, and precipitating it by potassa. This oxide is used as a paint; but its colour must be perfectly white so that the zinc happens to contain a little iron, which is often the case with the zinc of commerce, the oxide obtained has a tinge of yellow, because it is mixed with a little yellow oxide of iron.

The protoxide, or zinc combined with a minimum of oxygen, is obtained by exposing the peroxide to a strong heat in an earthenware retort or covered crucible. From the experiments of Desormes and Clement, it appears that by this process zinc loses a portion of its oxygen, and assumes a yellow colour. According to the analysis of these chemists, the protoxide of zinc is composed of eighty-eight parts of zinc and twelve parts of oxygen. The reduction of the oxides of zinc is in operation of difficulty, in consequence of the strong affinity which exists between zinc and oxygen. It must be mixed with charcoal, and exposed to a strong heat in vessels which screen it from the contact of the external air.

Most of the simple combustibles combine with zinc.

Hydrogen gas dissolves a little of it in certain cases. It is not to be procured by hydrogen gas by dissolving zinc in diluted sulphuric acid. The gas thus obtained is as pure as any which can be procured. It carries along with it however a little zinc in solution; hence it is composed of the sides of the glass jars, and on the surface of the water over which it stands. This gas, if we believe the French chemists, contains often a little carburetted hydrogen gas; a proof that zinc frequently contains carbon. When this metal is dissolved in sulphuric acid, it deposits a black insoluble powder, which the French chemists found to be carburet of iron. It is uncertain whether it is carburet, or carbon combined with zinc, which gives occasion to the production of the carburetted hydrogen gas.

It is believed at present that sulphur does not combine with zinc in the metallic state; lead is said to form the combination artificially has succeeded. Sulphur unites with the oxide of zinc when melted along with it in a crucible. This was first discovered by Delsin in 1781. The experiment was afterward repeated by Moreau. The sulphurated oxide of zinc is of a dark-brown colour, and brittle. It exists native in great abundance, and is known by the name of black. Mr. Proust, however, has announced it as his opinion, that blende is a sulphuret of zinc, or a compound of sulphur and zinc in the metallic state.

Zinc may be combined with phosphorus, by dropping small bits of phosphorus into it while in a state of fusion. Pelletier, to whom we are indebted for the experiment, added also a little resin, to prevent the oxidation of the zinc. Phosphuret of zinc is of a white colour, and metallic splendour, but resembles lead more than zinc. It is somewhat malleable. When hardened or filed, it emits the colour of phosphorus. When exposed to a strong heat, it burns like zinc.

Phosphorus combines also with the oxide of zinc, and the salt which Margraf had obtained during his experiments on phosphorus. When twelve parts of oxide of zinc, twelve parts of phosphoric acid, and two parts of charcoal-powder, are distilled in an earthenware retort, and a strong heat applied, a metallic substance sublimes of a silver-white colour, which when broken has a vitreous appearance. According to Pelletier, the phosphuret of oxide of zinc. When heated by the blowpipe, the phosphorus burns, and leaves behind a glass, transparent while in fusion, but opaque after cooling. Phosphuret of zinc is oxidized by zinc obtained also when two parts of zinc and one part of phosphorus are distilled in an earthen retort. The products are, 1. Zinc; 2. Oxide of zinc; 3. A red sublimate, which is phosphuret of oxide of zinc; 4. Needle-shaped crystals of metallic brilliancy, and a bluish colour. These also Pelletier considers as phosphuret oxide of zinc.

Zinc does not combine with azote. Mutaric acid readily converts it into an oxide. Zinc combines with almost all the metals, and some of its alloys are of great importance.

Elective affinity may be united to gold in any proportion by evolution. The alloy is the whiter and more brittle, the greater quantity of zinc it contains. An alloy, consisting of equal parts of these metals, is very hard and white, receives a fine polish, and does not tarnish readily. It was therefore been proposed by Mr. Malouin as very proper for the spectrum of telescopes. One part of zinc is said to destroy the ductility of 100 parts of gold.

Platinum combines very readily with zinc. The alloy is brittle, pretty hard, very inodorous, of a bluish-white colour, and not so clear as that of zinc.

The alloy of silver and zinc is easily produced by fusion. It is brittle, and has not been applied to any use.

Zinc may be combined with mercury, either by triturating the two metals together, or by dropping mercury into melted zinc.

This amalgam is solid. It crystallizes when melted, and cooled slowly into lamelated hexagonal figures, with cavities between them. They are composed of one part of zinc and two and a half of mercury. It is used to rub on electrical machines, in order to excite a current of electricity.

Zinc combines readily with copper, and forms one of the most useful of all the metallic alloys. The metals are usually combined together by stratiifying plates of copper and zinc, or the oxide of zinc combined with carbolic acid, called calamine, and applying heat. When the zinc does not exceed a fourth part of the copper, the alloy is known by the name of brass. It is of a beautiful yellow colour, more fusible than copper, and not so apt to tarnish. It is malleable, and so ductile that it may be drawn into wire. Its density is greater than the mean. It ought to be by calculation 7.6395, but it actually is 8.3958; so that its density is increased by about 1/10th. When the alloy contains three parts of zinc and four of copper, it assumes a colour nearly the same with gold, but it is not so malleable as brass. It is then called pinbeck, and is used for the crown and prince Rupert's metal. Brass was known, and very much valued, by the antients. They used an ore of zinc to form it, which they called cadmia. Dr. Watson has proved that it was brass that the ancients used according to Columella. Their ass was copper, or rather bronze.

It is very difficult to form an alloy of iron and zinc. Wallerius has shown that iron is capable of combining with a small portion of zinc; and Malouin has shewn that zinc may be used instead of tin to cover iron plates, a process which indicates there is an affinity between the two metals.

Tin and zinc may be easily combined by fusion. The alloy is, much harder than zinc, and scarcely less ductile. This alloy is often the principal ingredient in the compound called pewter.

The alloy of lead and zinc has been examined by Wallerius, Gelert, Muthenbrock, and Gniein. This last chemist succeeded in forming the alloy by fusion. He put some into the mixture, and covered the crucible in order to prevent the evaporation of the zinc. When the zinc exceeded the lead very much, the alloy was malleable, and much harder than lead. A mixture of two parts of zinc and one of lead formed an alloy more ductile and harder than brass. A mixture of equal parts of zinc and lead, formed an alloy differing little in ductility and colour from lead; but it was harder and more susceptible of polish, and much more sonorous. When the mixture contained a smaller quantity of zinc, it still approached nearer the ductility and colour of lead; but it continued harder, more sonorous, and susceptible of polish, till the proportions approached to 1 zinc and 1 lead, when the alloy differed from the last metal only in being somewhat harder.

ZINIA, a genus of plants of the class Syngenia, order polygama superflua, and in the natural system arranged under the 40th order, composita. The receptacle is paleaceous, the pappus consists of two erect awns, the calyx is ovato-cylindrical and imbricated; the rays consist of five persistent entire florets. There are 5 species, some of them natives of Britain.

ZIRCON. This stone is brought from Ceylon, and found also in France and Spain, and other parts of Europe. It is commonly crystallized. The primitive form of its crystals is an octahedron, composed of two four-sided, pyramids applied base to base, whose sides are isoceles triangles. The inclination of the sides of the same pyramid to each other is 124° 52'; the inclination of the sides of one pyramid to those of another 82° 50'. The angle at the apex is 72° 44'. The varieties of the crystalline forms of zircon amount to seven. In some cases there is a foursided prism interposed between the pyramids of the primitive form; sometimes all the angles of this prism are wanting, and two triangular faces in place of each; sometimes the crystals are dodecahedrons, composed of a flat four-sided prism with hexagonal faces, terminated by four-sided summit with rhomoidal faces; sometimes the edges of this prism, sometimes the edges where the prism and summit join, and sometimes both together, are wanting, and we find small faces in their place. For an accurate description and figure of these various forms, we refer to Haeckel.

The texture of zircon is foliated. Fracture imperfectly conchoidal. Causes a very great double refraction. Specific gravity from 4.615 to 4.383. Colours various, from reddish or yellowish, sometimes it is limpid. Before the blowpipe, it loses its colour, but not its transparency. With borax
ZOO with The species formerly called hyacinth is of a yellowish-red color, mixed with brown. Its surface is smooth. Its lustre 3 to 4.

2. The variety formerly called jargon of Ceylon is either grey, greenish, yellowish brown, reddish brown, or violet. It has little external lustre. It is sometimes nearly opaque.

The variety, according to the analysis of Vanheulgen, is composed of 64.5 zirconia 32.0 silica 2.0 oxide of iron

ZIZANIA, a genus of plants of the class monocotyledon, order caryophylli; and in the natural system arranged under the 4th order, graminia. There is no male calyx; the corolla is a bivalved heartless globe, intermixed with the female flowers; there is no female calyx; the corolla is an univalved, cucullated, and aristated globe; the style is bipartite, and there is one seed covered with the plaited corolla. There are 2 species; the aquatica and terrestris, none of which are native of Britain.

ZODIAC, See ASTRONOMY.

ZODIACAL light, a brightness sometimes observed in the zodiac, resembling that of the galaxy, or milky way. It appears at certain season, viz. towards the end of winter and in the spring after sunset, or before his rising in autumn and beginning of winter, resembling the form of a pyramid, lying lengthways with its apex along the zodiac, its base being placed obliquely with respect to the horizon. This phenomenon was first described and named by the elder Cassini, in 1683. It was afterwards observed by Fatio, in 1684, 1685, and 1686; also by Kirch and Eimmart, in 1685, 1689, 1691, 1693, and 1694.

ZOEIA, or a genus of plants of the class strutters, and order polygama. The receptacle is bristly; the pappus setaceous; the corolline of the radius liguilated; the calyx imbriicated. There is one species, the lentago.

ZONE, in geography and astronomy, a division of the terrestreal globe, with respect to the different degree of heat found in the different parts.

A zone is the fifth part of the surface of the earth, contained between two parallels. The zones are denominated torrid, frigid and temperate.

The torrid zone is a band surrounding the terrestrial globe, and terminated by the two tropics. Its breadth is 46° 59'. The equator, running through the middle of it, divides it into two equal parts, each containing 23° 29'. The ancients imagined the torrid zone uninhabitable.

The temperate zones are two bands, environing the globe, and contained between the tropics and the polar circles: the breadth of each is 43° 2'.

The frigid zones are segments of the surface of the earth, terminated, one by the antarctic, and the other by the arctic circle. The breadth of each is 46° 59'.

ZOONIS, a genus of insects of the order Coleoptera. The generic character is, antennae tectaceous; feelers four, filiform; jaw entire, longer than the feelers; lip emarginate. There are eight species.

ZOOLOGY, is that part of natural history which relates to animals. In order to divide the study of zoology, many methods of reducing animals to classes, genera, and species, have been invented: but as that of Linneus is undoubtedly the best, the most extensive, and the most generally adopted, we shall give a brief account of it.

Linneus divides the whole animal kingdom into six classes. The characters of these six classes are taken from the internal structure of animals, in the following manner:

Class I. Mammalia, or animals that suckle their young. The characters of this class are these: The heart has two ventricles and two auricles; the blood is red and warm; and the animals belonging to it are viviparous.

Class II. Aecte, or birds. The characters are the same with those of class I. excepting that the animals belonging to it are oviparous.

Class III. Amphibia, or amphibious animals. The heart has but one ventricle and one auricle; the blood is red and cold; and the animals belonging to this class have the command of their lungs, so that the intervals between the act of respiration and expiration are in some measure voluntary.

Class IV. Pisces, or fishes. The heart has the same structure, and the blood the same qualities, with those of the amphibia; but the animals belonging to this class are easily distinguished from the amphibia, by having no such voluntary command of their lungs, and by having external branchial or gills. Class V. Insecta, or insects. The heart has one ventricle, but no auricle; the blood is cold and white; and the animals are furnished with antennae or feelers. See Insect.

Class VI. Pauces, or worms. The characters are the same with those of class V. only the animals have no antennae, and are furnished with tentacula.

The first class, Mammmalia, is subdivided into seven orders; the characters which are taken from number, structure, and situation of the teeth.

Order I. The primates have four incisors, or fore-teeth, in each jaw, and one dog-tooth, N. B. By one dog-tooth, Linneus means one on each side of the fore-teeth in both jaws. This order includes four genera, viz. homo, simia, lemur, vesperilfo.

Order II. The bruta have no fore-teeth in either jaw. This order includes seven genera, viz. rhinoceros, elephas, tichocerus, bradypus, myrmecocystis, manis, dasypus.

Order III. The fera have, for the most part, six conical fore-teeth in each jaw. This order includes ten genera, viz. phoca, canis, felis, viverra, mustela, ursus, deldphus, tapir, siren, erinaceus.

Order IV. The glires have two fore-teeth in each jaw, and no dog-teeth. This order includes ten genera, viz. hystric, lepus, castor, mus, sciurus, myoxus, cavia, aratomy, dipus.

Order V. The pectora have no fore-teeth in the upper jaw, but six or eight in the under jaw. This order includes eight genera, viz. camelus, moschus, graffus, cervus, antilope, capra, ovis.

Order VI. The belæve have obtuse fore-teeth.

Order VII. The cete, or whale kind, have no upper character in the teeth, being very different in the different genera; before sufficiently distinguished from the other orders of mammalia, by living in the ocean, having pectoral fins, and fins and spiracles upon the head. This order includes four genera, viz. monodon, balaen, physeter, delphinus.

The generic characters of the mammalia are, like those of the orders, almost entirely taken from the teeth, excepting the vesperillo, which, besides the character of the order derived from the teeth, has this further mark, that there is a membrane attached to the feet and sides, by means of which the creature is enabled to fly: the hystric, whose body is covered with sharp spines; and the whole order of pectora, whose genera, besides the characters taken from the teeth, are distinguished into those which have horns, those which have no horns, and by peculiarities in the horns themselves.

The specific characters are very various, being taken from any part of the body which possesses a peculiar uniform mark of distinction. As examples of these characters are to be found in a description of each genus; it is unnecessary to say any thing further concerning them in this place.

The second class, Aecte, is subdivided into six orders; the characters of which are taken from the structure of their teeth: and the whole order of pectora, whose genera, besides the characters taken from the teeth, are distinguished into those which have horns, those which have no horns, and by peculiarities in the horns themselves.

The specific characters are very various, being taken from any part of the body which possesses a peculiar uniform mark of distinction. As examples of these characters are to be found in a description of each genus; it is unnecessary to say any thing further concerning them in this place.
The generic characters of this class are taken from peculiarieties in the head, the mouth, the teeth, the nostril, the rays of the gill in the membrane of the gills, the eyes, the general figure of the body, the nature of the tail, the situation of the spiral.

The specific characters are taken from peculiarieties in all the parts above enumerated, and many others.

The fifth class, Fascea, is subdivided into seven orders, the characters of which are taken from the wings. See the article Insect.

Order I. The coleoptera have four wings, the two superior ones being crassuscoxous, and furnished with a straight spine. This order comprehends forty-seven genera, viz. scarabaeus, lucanus, dernestes, melrythus, buphis, tritonea, hippocrepis, lyon, panus, bostrichus, anturhens, nitidula, coccinella, curculio, brenus, atelacius, erodium, staphylinus, scarus, zygia,模拟, teobus, baccinio, cophra, paras, hippus, hydropis, vespa, vespa, cantharida, criocerus, elater, catorus, alopus, carabus, ylita, serropalpus, cerambyx, lepura, rhinocerous, zonitis, cindelida, dyctious, torficula.

Order II. The nemiptera have four wings, the two superior ones being semi-tergosternal, and incumbent, i.e. the interior edges lie above one another. This order includes fourteen genera, viz. blatta, pneumonia, minutis, grylius, fulgora, cida, notocopa, nepa, cicada, macrocephalus, sphix, cherus, coccus, thrips.

Order III. The lepidoptera have four wings, all of them imbricated with scales. This order contains three genera, viz. papilio, sphinx, phaenala.

Order IV. The neuroptera have four wings, interwoven with veins, like a piece of network, and no stig in the anus. This order includes seven genera, viz. libella, hiperbenacis, myrmex, phycnus, panocy, rophidia.

Order V. The hymenoptera have the same characters with the former, only the anus is armed with a stig. But this mark is peculiar to the females and nesters; for the males have no sting. This order comprehends fifteen genera, viz. cynips, tentrelo, sirex, ichneunon, sphex, scolia, thynnus, leucopis, tipula, chalcis, carypis, vespa, apis, formica, mutilla.

Order VI. The diptera have two wings, and two clavated halteres or balances behind each wing. This order contains twelve genera, viz. diops, tipula, musca, tabanus, ennis, concept, oestra, asilus, stenomyxus, culex, bonbyllus, hippobosca.

Order VII. The aptera have no wings. This order contains fifteen species, viz. lepisma, podura, termes, pediculus, pules, acarus, hydracina, aranea, plagni, scorpio, cancer, monocolus, oniscus, scolopendria, julus.

The sixth class, Pernes, is divided into five orders.

Order I. The intestina are the most simple animals, being perfectly naked, and without limbs of any kind. This order contains twenty-one genera, viz. acaris, trichocopa, luscinia, tilia, syclor, ligula, linguaster,strongylus, cinchohynilus, harca, cecirrounded, caryophyllus, fasciata, terrama, furia, myrme, gordius, hirundo, liricdens, sipunculus, planaria.

Order II. The mollusca are likewise simple naked animals, without any shell; but they are brachiated, or furnished with a kind of limbs. This order comprehends thirty-one genera, viz. actinia, clava, mannnertia, pedicularia, asidica, salpa, dagys, pterochilus, limax, sphylla, dentes, tethis, holothuria, terbellia, triton, cepha, ceps, libara, lema, sceylh, glaucus, alpisdrita, amphitrite, spone, neris, nia, physophora, medua, bocernia, asteria, eccenia.

Order III. The testacea have the same characters with those of order II. But are covered with a shell. This order includes thirty genera, viz. chiton, lepon, phalos, mya, solen, tellenia, cardium, naetera, donax, venus, spondylus, chama, arca, ostrea, anoxia, mytilus, pinna, argonauta, nautilus, conus, cyprca, bulla, voluta, sacchurn, stransbus, murex, trochus, turbo, helix, moria, bollus, patella, denulatum, scalaria.

Order IV. The zoophyta, are compound animals, furnished with a kind of flowers, and having a vegetating root and stem. This order contains fifteen genera, viz. tubipora, madrepora, millepora, acelopora, isis, antipathes, gorgonia, oleye, siphonga, flusta, tubularia, corallia, serpulaita, pernula, hydra.

Order V. The tunicata consists of very small simple animals. This order contains nine genera, viz. brachionus, vorticella, trichoda, ceraria, leucopeora, gonium, copoda, paramecium, cycloidium, bursaria, virbio, enchelis, bacillaria, volvox, monas.

For more particular information concerning the several branches and subjects of zoology, the reader may consult the various articles above referred to, and he will find most of the genera described in their order in the alphabet.

ZOOPHYTA, in natural history, the 4th order under the class of Vermin. See Zoology.

ZOSTERA, a genus of plants of the class: gynandria, order polyanthia; and in the natural system arranged under the second order, pipirica. The spadix is linear, and fertile only in the last flower; the calyx is five-parted; petals five; capsules five. There is one species, the amasa, resembling quassia, a shrub of Guiana.

ZYG. See SQUAMUS.

ZYGIA, a genus of insects of the order Coleoptera. The generic character is, antennae moniliform: feelers equal, filiform: lip elon-gated, membranes: jaw one-toothed.

ZYGOPHILYUM, bean-caper, a genus of plants of the class of decanaria and order monogyna, and in the natural system arranged under the 14th order, gramineae. The calyx is five-leaved; petals five; nectarium ten-leaved, covering the germ; envelopes five-celled. There are 14 species, partly shrubby, and some of them natives of warm climates, though some of them are hardy enough to endure the open air in this country.
INDEX TO THE TREATISES
IN THE SECOND VOLUME.

INFANCY.
Air and exercise, remarks on, 14 b.
Bathing of infants, remarks on, 13 a.
Bowels, disorder in, 18 a.
Clothing of infants, remarks on, 13 a, b, c.
Croup, remarks on this disorder, 18 a.
Diet of infants, 11 a.
Diseases of infancy, 15 a.
Mesenteric atrophy, remarks on, 15 a; con.
sumptions, 15 a.
Nurses, remarks on, 13 a.
Fugitives, the practice of administering them to
new-born children, iniquitous, 12 b.
Rickets, remarks on, 18 a.
Sucking, importance of this being done by the
mother, 12 a.
Teething, affections occasioned by, 18 a.
Temperature of infants, 12 a.
Washing of infants, remarks on, 13 a.
Water in the head, remarks on this disease, 16 c;
chronic internal, b; chronic external, 17 a;
acute hydrocephalus, b.
Wetting, time of, 12 c.
Worms, remarks on, 17 a.

INSTRUMENTS, MATHEMATICAL.
Compasses, plain, 23 c; drawing, b; projection,
57 a.
Gunter’s lines, 26 c.
Line of chords, to construct, 25 d; of rhumbs,
13 a; of sines, b; of tangents, b; of saccata, b;
of latitudes, 25 a; of latitude, b; of hours, b; of inclinations of meridians, b.
Lines of equal parts, 24 b.
Parallel ruler, 24 a.
Pen and pencil, drawing, 24 a.
Protractor, 24 a.
Scale, plain, 24 a.
Sector, 25 c to 35 c.

MAGNETISM.
Attraction and repulsion, magnetic, account of,
96 a.
Compass, mariner’s, construction of 96 c; azi.
moth, 97 a.
Compass-nails, best methods of communicating
magnetism to them, 96 a, b.
Deviation of the magnet from the true meri.
dian, 95 a.
Dip of the needle, 95 a.
Dipping-needle, construction and use of, 97 a,
95 b.
Directive property of the magnet, first discov.
dery of, 95 a.
Experiments to illustrate the magnetic theory,
97 b.
Horse-shoe magnet, and its properties, described,
96 a.
Inclination, magnetic, 95 a.
Instruments, mechanical, construction and use of
the principal, 96 c.
Iron, methods of making it magnetic, 95 a.
Magnet, description of, 95 b.
Needles, magnetic, construction and use of, 96 c.
Polarity of the magnet, account of, 94 c.
Poles of the magnet, described, 93 c.
Properties, characteristic of the magnet, 98 a.
Steel, its difference in receiving magnetism, very
great, 96 a.

MATERIA MEDICA.
Antacids, 115 c.
Anthemelitics, 116 c.
Antip fistics, 111 a, b.
Arnica, 111 c to 112 a.
Astringents, 112 b; vegetable, b; mineral, c.
Cathartics, 113 b.
Coffee considered as a drink, 109 b.
Definition of the materia medica, 107 a.
Demulcents, 116 b.
Diaphoretics, 114 c, d.
Dietetics, 107 b.
Diluents and emollients, 116 b.
Dried, 114 a; saline, b; vegetable, c; from the
animal kingdom, ib.
Dressing, virtues, remarks on the different meth.
ods of, 108 a.
Drink, remarks on, 109 a.
Emetics, 113 c; from the vegetable kingdom, 113 a;
from the mineral kingdom, id.
Emmenagogues, 112 c; from the class of tonics,
114 a; of antispasmodics, b; of cathartics, b.
Epistaxis and rubefaciens, 115 b.
Erchines, 116 a.
Escharotics, 116 a.
Expectorants, 114 a, 115 a.
Food, animal, remarks on, 108 a; vegetable, b.
Laxatives, 113 b.
Lithotriptics, 115 a.
Medicinals, 109 c; classification of, 110 a.
Milk and its productions, remarks on, 108 b.
Narcotics, enumeration of, 110 b to 111 b.
Organic life, principles of, 107 a.
Purgatives, 113 b.
Refrigerants, 115 a.
Silagogues, 115 a.
Tea considered as a drink, 109 a.
Tonics, 111 a; from the mineral kingdom, b;
from the vegetable kingdom, b.
Water, remarks on the different kinds of, as:
articles of drink, 109 a; spring, well, river,
lake, and rain water, b; snow and hail wa-
ter.

MECHANICS.
Balance, principles and theory of the, 124 c; cir.
cumstances to be attended to, in order to have
it as perfect as possible, b.
Capstan, principles of, 125 b.
Compound machines considered, 127 b.
Cranes, principles of, 126 c.
Horses, important points of attention in the ap.
plication of them as moving powers in ma-
chinery, 127 a, 128 a.
Inclined plane, principles of, 126 a.
Lever described, 128 a; different sorts of, and
illustrations of these: the first kind, b; the
second kind, c; the hammer-lever, 124 a.
Mechanics, definition and vast importance of
this science, 125 a.
Men and horses; of the application of, as mov-
ing powers in machinery, &c. 127 c.
Powers, mechanical, defined, 125 a; enumer.
ated, b.
Pulley, different kinds of, and principles and
operation of each, 126 a.
Screw, principles of, 196 c; illustration of its
effect, 127 a.
Steel-yard, principles of, 125 a.
Wedge’s, principles of, 126 b.

Wheel and axle, principles and operation of,
125 a to 126 a.
Wheels and pinions, ratio of their respective ve-
locities illustrated, 127 c.

MEDALS.
British coins, early, 150 b; those of the Saxon
monarchy, c, since the Conquest, c; first
brass, c; gold, 151 a.
Coinage, question of the origin of, 128 a.
Coins and medals, the knowledge of, probably
first introduced into this country from Italy,
128 b.
Definition of the term medal, 128 b.
Greek coins, list and value of, 126 c; silver, b;
copper, 129 a; gold, b.
Legends on the Greek and Roman coins, 130 a.
Medallions, ancient, 130 a.
Mediterranean coins, early 190 c; of the kings
and queens of Macedon, Sicily, &c. b; of
Roman emperors, ib.; of kings on Greek
coins, ib.
Review of medals among the Greeks and Ro-
mans, 130 a.
Roman coins, list and value of, 129 a; brass, b;
silver, b; gold, c.
Study of medals, its antiquity, 128 b.
Utility of medals in the sciences, 129 b.

MEDICINE.
Adynamia; their genera, symptoms, and meth.
ods of cure, 147 a to c.
Blood, discharges of: their genera, symptoms,
and methods of cure, 144 a to 145 a.
Hocheave, the founder of the humoral patho.
lology, 132 c.
Cachexies, class of, 132 a.
Classification of disease, 143 c.
Cold affusion in fever, 136 b to 137 a.
Cold air, use of, in fever, 137 b.
Comata; their genera, symptoms, and methods
of cure, 146 b to 147 a.
Critical days in fever, 139 b.
Darwin, Dr., his theory, and objections to it;
123 a, b, 135 a.
Definition of medicine, 131 a.
Diseases, classification of, 133 b.
Drospay; its genera, and methods of cure, 133 a
to 134 a.
Empirics and Dogmatists, sects of, 131 b.
Epicurean philosophy introduced into the schools
of medicine, 131 c.
Eruptions; their genera, symptoms, species, and
methods of cure, 145 a to 144 a.
Fever, definition of, 134 a; phenomena of, b; s;
species, b; Cullen’s genera, c; its exciting
causes, b; proximate cause, 135 a; theory of
Dr. Cullen respecting fever, and objections to
this, b; of Dr. Darwin, and objections, ib.;
treatment in, 136 a; of cold and rapid afflu.
sion, cold and alburn, cold water internally, and
cold air, in, b; other refrigerants, 137 c; of
the use of animal food, 138 a; sudorifics, b;
purgatives and emetics, c; unfavourable signs
in fever, 129 b; critical days, b; recapitula.
tion of the treatment of fever, 139 b; treat.
ment of continued fever during the first three
or four days, ib.; after the fifth or sixth day,
b; treatment of intermittent fever, ib.
Fever-houses considered, 139 a to 140 a.
Galen, his doctrines, 131 a.
INDEX TO THE TREATISES.

RHEOTORIC.
Amplification considered, 579 b.
Antithesis, 581 a.
Apostrophe, 581 a.
Arguments, disposal of, 579 a.
Arrangement or order, the most important point in every composition, 577 e; execution of this, 578 a.
Beauty of style, 582 a.
Climate, 550 a.
Definition of rhetoric, 577 c.
Diphthong considered, 579 a.
Harmony of style, 581 a.
History, method of writing, 578 b; its effect, 579 b; civil history, 585 a.
Hyperbole, 579 c.
Inversion, 581 a.
Irony, 580 a.
Metaphor, 580 b, 592 a.
Mettomy, 580 b.
Perspicuity of style, 580 a.
Prosopopeia, 581 a.
Purity of style, 570 a.
Style, 579 c; the various kinds of, specified, 582 b.
Sublimity of style, 581 c.
Transitions considered, 579 b.
Unity of design and action considered, 578 a.
Vigour or energy of style, 580 b.

SCULPTURE.
Ancient art of sculpture, 633 b.
Definition of sculpture, 630 a.
English sculpture, 640 a.
French sculpture, 639 a.
Grecian sculpture, 633 a; causes of its excellence, 636 a; its character, 636 b; its decline, 637 a.
History of sculpture, 633 a.
Italian sculpture, modern, 639 a to e.
Model, use of the, 639 a.
Modern art of sculpture, 638 a.
Modes of process, different, in sculpture, 631 c.
Oriental sculpture, ancient, 633 c to 634 a.
Roman sculpture, ancient, 638 a to c.
Stone and marble, sculpture in, 639 a.
Study, methods of, 631 a.
Wood, sculpture in, 638 a.

SHIP-BUILDING.
Construction of ships, 660 a.
Dimensions considered, 658 b, c.
Guns, to make a ship carry hers well out of the water, 638 a.
Masts, 661 a.
Pitching hard, to make a ship go smoothly through the water without, 655 b.
Plane, art of delineating ships on, 656 a.
Plane of elevation of a sixty-gun ship described, 659 a; plane of projection, 659 b; horizontal plane, 659 a.
Sail, to make a ship carry a good one, 658 b.
Steer, to make a ship, well, 658 a.
Stowing and trimming of ships, importance of doing this judiciously, 661 a.
Wind, to make a ship keep a good one, 658 b.

SURGERY.
Abdomen, wounds in, 738 a.
Amputation considered, 734 c, 735 a, 742 a.
Aneurisms, 739 a; diagnostic marks of, &c; causer, 739 c; treatment, c.
Arteriotomy, 746 a.
Bite, wounds of, 744 a to c.
Blood-letting, 747 c; topical bleeding, 748 a.
Bones, diseases of, 747 a.
Breast and lung wounds, wounds of, 794 a.
Breastotomy, 743 a.
Cancer considered, 746 a; its causes and peculiari- ties, b; treatment, b; operation, b.
Chin, wounds in the cavity of, 738 b.
Contused and lacerated wounds, 739 a.
Corns, 747 a.

qualities, 398 a; grinding the colours, and preparing them for the pallet, r, c; hair-pencils; manner of choosing them, &c, 339 a; ivory; method of choosing, bleaching, and preparing, b; mixing compound tints for the face, c; colours proper for men's draperies, 340 a; painting the face, b; general observa-

Plants, Physiology of.

Sleep, &c. considered, 438 a.
Smell, the sense of, considered, 428 a.
Speech, the faculty of, considered, 429 b.
Touch, the sense of, considered, 428 a.
Veins, of the action of, 436 b.
Virility, state of, 431 a.
Voice (the), considered, 429 a.

PNEUMATICS.
Air, particulars in which it differs from all other fluids, 453 c.
Air-gun described, and its principle explained, 460 b.
Air-pump, description of, 456 a; attention necessary in making experiments with, 456 b; American, described, 460 c, 461 c; marks on the respective merits and imperfections of these instruments, 462 a, b.
Elasticity of air, 457 a.
Miscellaneous experiments, 457 c.
Pressure of the air upon the body of a middle-sized man, 457 a.
Prince, Mr., his air-pump described, 461 a.
Rarity of the air at different heights above the surface of the earth, 457 b.
Suction, the idea of, disproved, 456 c.
Vacuum, the Torricellian, 456 c.
Weight of air demonstrated, 456 a.

POETRY.
Ancient poetry considered, 463 b.
Arabian poetry, character of, 463 a.
Blank verse considered, 466 b.
Classical poetry considered, 464 a.
Classification, poetical, 467 b.
Comedy, origin of, 464 c.
D: fision of poetry, 463 a.
Description, poetical, 470 b to 471 b.
Didactic poetry, 468 a.
Dramatic poetry, 469 a.
Elegiac poetry, 467 c.
English versification considered, 465 b.
Epic poetry, 468 a.
Grecian poetry considered, 464 a to c.
Hebrew poetry, character of 463 b.
Imagery, a prose passage rich in, 463 b.
Lyric poetry, 468 a.
Metre of poetry, evidently borrowed from the simple melodies of music, 463 a.
Metrical harmony, and poetical emotion, 469 c.
Modern poetry, origin of, 465 a.
Ode, construction of, 464 b.
Pastoral poetry, 468 a.
Roman poetry considered, 464 a, 465 a.
Satirical poetry, 468 a.
Song considered, 469 a.
Tragedy, origin of, 464 a.
Troubadours, 465 a.
INDEX TO THE TREATISES.

Naval warfare, 879 a.
Navy, British; earliest state, and progress of, 876 b to 876 b.
Principles, general, in modern warfare, 882 a.
Signals used in ancient naval combat, 878 b.

WATER.

Acids, kinds and proportions of, contained in mineral waters, 887 a; method of ascertaining the proportions of mineral acids combined in waters, 891 a.
Acidulous mineral waters, composition of, 888 a.
Air, kinds and proportions of, contained in mineral waters, 887 a; methods of detecting the proportions of aerial fluids in water, 891 a.
Alkali contained in mineral waters, 887 a; method of ascertaining the proportion of alkaline carbonate present in waters, 891 a.
Both water, analysis of, 888 a.
Chalybeate waters, composition of, 888 a.
Common water, its properties and kinds, 886 a.
Earth contained in mineral waters, 887 a; methods of detecting the proportions of earthy carbons in water, 891 a.
Fluidity not the most simple state of water, 886 a.
Hepatic, or sulphureous waters, composition of, 888 a.
Lake-water, nature of, 886 a.
Marsh-water, nature of, 886 a.
Mineral waters, 886 c, 887 a; table of the component parts of many mineral waters, 888 ; method of analysing them, 888 a; methods of detecting their presence in waters, 890 a; of ascertaining their proportions, 892 a.
Nitrates, methods of detecting their presence in waters, 890 b; of ascertaining their proportions, 892 a.
Rain-water, nature of, 886 a.
River-water, nature of, 886 a.
Sulphate waters, composition of, 888 a.
Salt contained in mineral waters, 887 a.
Spring-water, nature of, 886 a.
Substances occurring in mineral waters, means of detecting them all, 888 a to 889 e.

Vol. II. 6 B
UNIVERSAL HISTORY, ANCIENT and MODERN, from the earliest Records of Time to the General Peace of 1802; complete in Twenty-Six Volumes, illustrated with Plates, and illustrated with Maps, Indexes, and Chronological Tables.

By WILLIAM MAYOR, LL. D.
Vicar of Hurley, in Berkshire; Rector of Stonefield, Oxon; Chaplain to the Earl of Moira, &c. &c.

There are Two Editions; which may be had done up in three kinds of Binding, at the following Prices:

- COMMON PAPER - in Boards - £4 13 6
- Ditto, Ditto - half bound - £5 0 0
- Ditto, Ditto - calf gilt - £5 15 6
- TIME and LARGE PAPER - in Boards - £6 5 0
- Ditto, Ditto - half bound - £6 16 6
- Ditto, Ditto - calf gilt - £7 10 0

In the Execution of this extensive and arduous Undertaking, through all its parts, the Editor has been solicitous to keep at an equal distance from Prolixity and Brevity. He has studied to be clear, distinct, comprehensive, and exact. To all persons, therefore, who wish to possess at a moderate Expence, a complete body of Universal History, brought down to the present Time; to Schools in particular, to Students, and to circulating and private Libraries; the Work will unquestionably prove a valuable and desirable acquisition.

THE HISTORY OF GREAT BRITAIN, FROM THE REVOLUTION in 1688 (when Hume's History terminates), to THE PEACE of AMIENS in 1802. A New Edition, printed in Twelve Volumes, octavo, uniformly with the History of Mr. Hume, price Six Guineas in boards; or any two Volumes separately, price 21s. in boards.

By WILLIAM BSELHAM, ESQ.
Mr. HUME'S History was brought by that writer down to the period of the Revolution, and Mr. Belsham has taken up the narrative from the Revolution and brought it down to the Peace of Amiens.

Both works form an uniform Series of Twenty Volumes; and they may be had of every Bookseller in Town and Country, price Nine GUINEAS in boards.

Persons already possessing Mr. Hume's History, may have Mr. Belsham's entire Work by itself, in Twelve Volumes, for S.X GUINEAS in boards.

And as the latter part of Smollett's General History was frequently sold, previously to the appearance of Mr. Belsham's Work, as a Continuation of Hume to the Death of George the Second, Mr. Phillips thinks it proper to observe, that Mr. Belsham's History of the Reign of George the Third may be had separately, to complete Hume and Smollett, in Eight Volumes, price FOUR GUINEAS in boards.

THE LIFE of GEORGE WASHINGTON, Commander in Chief of the American Forces during the War which established the Independence of his Country, and FIRST President of the United States of America; compiled under the Inspection of his Nephew and Heir, the HONOURABLE BUSHROD WASHINGTON, from original papers, bequeathed to him by his deceased relative; in Two Editions: one in SUPER MEDIUM QUARTO, price Seven Guineas and a Half in boards, and another in DEMY OCTAVO, price Two Guineas and a Half in boards; the whole illustrated with numerous Views, Maps, and Plans.

By JOHN MARSHALL, Chief Justice of the United States, &c. &c.

MODERN LONDON: consisting of a Brief History of the Metropolis of the British Empire, and of a Full and Circumstantial Description of its Present State; illustrated by beautiful charac-
teristic Engravings, representing all the Places of great public Resort, and the principal Buildings in one large and elegant Quarto Volume, illustrated with Sixty Engravings, by the first Artists, plain and coloured, price Three Guineas in boards.

This Work is the only existing Publication of sufficient Consequence and Authority to illustrate to Foreigners and Strangers the Wealth, Splendour, Population, and Magnificence, of the largest City in the World. It was published expressly with that Design and it is calculated to convey to the remotest Nations the clearest Ideas relative to London, and to preserve the Recollection of its most interesting Features to those persons who are or have been familiar with them.

THE FARMER'S CALENDAR; containing a full Account of the BUSINESS necessary to be performed on all kinds of Farms during EVERY MONTH of the Year, with the latest Improvements, and the Mode of executing them. The Sixth Edition, improved; in One large Volume, octavo, price Half a Guinea in boards.

By ARTHUR YOUNG, Esq. F. R. S.
Secretary to the Board of Agriculture, and Member of various Philosophical and Agricultural Societies in Europe and America.

A COMPLETE SYSTEM of PRACTICAL AGRICULTURE; including all the MODERN IMPROVEMENTS and DISCOVERIES, and the results of all the attention and inquiry which have been bestowed on this important Science, during the last thirty years; the whole combining and explaining fully, extensively, and completely, the PRINCIPLES and PRACTICE of the MODERN ART of HUSBANDRY in all its branches and relations. A new and improved Edition, in two large volumes quarto, illustrated with nearly One Hundred Engravings, representing the most improved Implements, the various Grasses, and the principal Breeds of Sheep and Cattle, price Four Guineas in Boards.

By R. W. DICKSON, M. D.
Honorary Member of the Board of Agriculture.

CARR'S TRAVELS IN IRELAND.

THE STRANGER in IRELAND, or a Tour through the Southern and Western PARTS of that Country, in the Year 1803; containing Views of the State of Society, Manners, and Opinions, among the People of Ireland, interspersed with numerous characteristic Anecdotes, in an elegant Volume quarto, decorated with Seventeen beautiful Engravings, price 4½s. in Boards.

By SIR JOHN CARR.

TRAVELS ROUND the BALTIC, through DENMARK, SWEDEN, RUSSIA, POLAND, and PRUSSIA; with numerous Plates, price 4½s. in boards.

By SIR JOHN CARR.

AN ILLUSTRATION of the ANATOMY of the HUMAN EAR, accompanied by Views of that ORGAN, accurately drawn, of the Natural Size, from a Series of Dissections. To which is added, a TREATISE on its DISEASES, and the proper TREATMENT, price 2½s. in Boards, elegantly printed in One Volume folio, with splendid Engravings by Heath.

By J. C. SAUNDERS, Demonstrator of Practical Anatomy in the Anatomical School in St. Thomas's Hospital, and Surgeon to the London Dispensary for Diseases of the Eye and Ear.

TRAVELS in GERMANY, HOLLAND, FLANDERS, and FRANCE, TO PARIS: With numerous particulars, relative to the Present State of that Capital; its Festivals, Literature, Characters, Paintings, Musick, Theatres, Gardens, Institutions, Architecture, and especially the Manners of the People, &c. &c. In two elegant Volumes, Quarto, decorated with a great number of Vignettes, with a separate Atlas of large and splendid Engravings, representing the principal Objects and Buildings in Paris, price Eight GUINEAS in boards; or, with the Plates reduced in size, and folded in the Volumes, price Five GUINEAS in boards.

By THOMAS HOLcroft.

ANIMAL BIOGRAPHY: or, ANECDOTES and CURIOUS FACTS, relative to the Manners, Habits, and Economy, of the WHOLE ANIMAL CREATION, collected from works of Authority in all Languages, from expensive Books of Natural History, from Voyages and Travels, and from every authentic Source. The whole clasped and arranged according to the system of Linnaeus. A new Edition, considerably extended and improved, in Three large Volumes, 8vo, price 11. 10s. in boards.

By the Rev. W. BINGLEY, Fellow of the Linnaean Society, and late of St. Peter's College, Cambridge.
